THE
AMERICAN CYCLOPÆDIA:

A

Popular Dictionary

OF

GENERAL KNOWLEDGE.

EDITED BY

GEORGE RIPLEY AND CHARLES A. DANA.

WITH SUPPLEMENT.

VOLUME XIV.

PRIOR-SHOE.

NEW YORK:
D. APPLETON AND COMPANY,

1, 3, AND 5 BOND STREET.

LONDON: CAXTON HOUSE, PATERNOSTER SQUARE.

1883.

ENTERED, according to Act of Congress, in the year 1862, by D. APPLETON AND COMPANY, in the Clerk's Office of the District Court of the United States for the Southern District of New York.

ENTERED, according to Act of Congress, in the year 1875, by D. APPLETON AND COMPANY, in the Office of the Librarian of Congress, at Washington.

ENTERED, according to Act of Congress, in the year 1880, by D. APPLETON AND COMPANY, in the Office of the Librarian of Congress, at Washington.

ENTERED, according to Act of Congress, in the year 1883, by D. APPLETON AND COMPANY, in the Office of the Librarian of Congress, at Washington.

Among the Contributors to the Fourteenth Volume of the Revised Edition are the following:

- Prof. CLEVELAND ABBE, Washington, D. C.
RAIN.
RAIN GAUGE.
- HENRY CAREY BAIRD, Philadelphia.
SAVINGS BANK.
- HON. GEORGE BANOROFF, Washington, D. C.
SANDYS, Sir EDWIN.
SANDYS, GEORGE.
- WILLARD BARTLETT.
PUNJAB.
SAHARA.
SARAWAK.
- A. M. BELL, M. D., Brooklyn, N. Y.
PUSTULE, MALIGNANT.
- JULIUS BING.
RABELAIS.
ROUSSEAU, JEAN JACQUES,
SAINT PETERSBURG.
SCHILLER, JOHANN CHRISTOPH FRIEDRICH VON,
SERVIA,
and other articles in biography, geography, and history.
- WILLIAM BLAIKIE.
ROWING.
- FRANCIS C. BOWMAN.
RUBINSTEIN, ANTON.
SCHUBERT, FRANZ.
SCHUMANN, ROBERT.
- EDWARD L. BURLINGAME, Ph. D.
PRUSSIA (in part).
PUMPELLY, RAPHAEL.
PYGMY.
- ROBERT CARTER.
PSALMANAZAR, GEORGE.
PTOLEMY I., II., III.
RALEIGH, Sir WALTER.
SEWARD, WILLIAM HENRY.
- JOHN D. CHAMPLIN, Jr.
QUEENSLAND,
RED SEA,
RING,
SAMOAN ISLANDS,
SANTO DOMINGO,
SCOTLAND (in part),
and other articles in geography and history.
- Prof. E. H. CLARKE, M. D., Harvard University.
SARSAPARILLA (medical part),
SASSAFRAS (medical part),
SENNA (medical part),
and other articles in materia medica.
- THEODORE P. COOK, Utica, N. Y.
SEYMOUR, HORATIO.
- Hon. T. M. COOLEY, LL. D., Michigan University, Ann Arbor.
PRIZE (in part),
PRIZE MONEY,
RECORD (in part),
and other legal articles.
- JOSEPH CROWDY, St. John's, Newfoundland.
SAINT JOHN'S.
- Prof. J. C. DALTON, M. D.
PULSE,
QUINCY,
RESPIRATION,
and other medical and physiological articles.

THE

AMERICAN CYCLOPÆDIA.

PRIOR

PRIOR, Matthew, an English poet, born at Wimborne-Minster, Dorsetshire, July 21, 1664, died at Wimpole, Cambridgeshire, a seat of Lord Oxford, Sept. 18, 1721. He graduated at Cambridge in 1686. Here he formed an intimacy with Charles Montague, afterward earl of Halifax, with whom he wrote "The City Mouse and Country Mouse" (1687), in ridicule of Dryden's "Hind and Panther." He was appointed in 1690 secretary of the embassy at the Hague, and became one of the gentlemen of the bedchamber to William III. In 1695 he wrote an ode on the death of Queen Mary. In 1697 he was appointed secretary of the commissioners who concluded the treaty of Ryswick, and in 1698 secretary of the embassy at the court of France. In 1699 he was made under secretary of state, but losing his place shortly after, received in 1700 the appointment of commissioner of trade. The same year he published his *Carmen Seculare*, a panegyric on King William. In 1701 he was elected a member of parliament from East Grinstead, and soon after he changed his politics, becoming a violent tory. In 1711 he was sent on a private mission to Paris with proposals of peace. Bolingbroke went to Paris as ambassador to hasten the negotiations; and Prior, who was in company with him, after Bolingbroke's return became the ambassador. When, in August, 1714, the whigs had regained office, Prior was recalled, and was at once arrested on a charge of treason. While a prisoner in his own house for two years he wrote "Alma, or the Progress of the Mind." After his release he published his poems by subscription, through which he realized 4,000 guineas. Lord Harley, son of the earl of Oxford, added an equal sum for the purchase of Down hall in Essex, which was settled upon Prior for his life. He was buried in Westminster abbey, and a monument was erected to his memory,

PRISCILLIAN

for which he left £500 in his will. The best of the old editions of his poems is that of 1791 (2 vols. 8vo). An edition with a life by Mitford (2 vols. 12mo) was published in 1835.

PRISCIANUS, a Roman grammarian, who lived about A. D. 500, and is supposed from his surname Cæsariensis to have been born or educated at Cæsarea. He was a pupil of Theodistus, and taught grammar at Constantinople, was in receipt of a salary from the government, and was probably a Christian. His *Commentariorum Grammaticorum Libri XVIII* contains a large number of quotations from Greek and Latin writers not otherwise known, and a parallel between the Greek and Latin languages. He also wrote a "Grammatical Catechism on twelve Lines of the *Æneid*," a "Treatise on Accents," one on "The Metres of Terence," some short poems, and several translations from the Greek; and the acrostics prefixed to the plays of Plautus are ascribed to him. His name is familiar in the phrase *diminuere Prisciani caput* (to break Priscian's head), commonly applied to those who use false Latin.

PRISCILLIAN, the founder of a religious sect in Spain and Gaul, born in the neighborhood of Cordova, died in Treves in 385. He was of high birth, and possessed wide learning and great rhetorical talents. It is said that he was instructed by a certain Egyptian called Mark, and by Elpidius and Agape. He appeared as a religious reformer with the pretension of having been called to preach the true doctrine and a spiritual asceticism, and to found within the Catholic church a special secret society of initiated and saints. He was excommunicated by a synod held at Saragossa about 380, but to no effect, as he was soon after ordained bishop of Ávila. The emperor Gratian was thereupon persuaded to publish an edict exiling Priscillian and his friends, but a revocation of the edict

was obtained by bribing some of the court officials. Another synod, held at the instance of Bishop Ithacius at Bordeaux in 384, when Maximus had usurped the throne, again gave an adverse decision. Priscillian appealed before the emperor, who sentenced him to death and decreed the confiscation of his property. Priscillian's execution is the first instance of a Christian condemned to death for heresy. The doctrines held by the Priscillianists were a mixture of Manichæism and Gnosticism.

PRISM, in geometry, a solid bounded by plane faces, of which two that are opposite are equal, similar, and parallel, and are called the bases of the prism; the other surfaces are parallelograms. The axis is the line connecting the centres of the bases. The prism is triangular, square, pentagonal, and so on, according as the figure of the bases is triangular, square, pentagonal, &c. It is right or oblique according as the sides are perpendicular or oblique to the bases. A right prism is regular when its bases have the figure of a regular polygon. The prism corresponds among bodies with plane surfaces to the cylinder among bodies with curve surfaces.—In optics, a prism is a portion of a refracting medium bounded by two plane surfaces inclined to one another. The line in which these two surfaces meet, or would meet if produced, is the edge of the prism; their inclination is called its refracting angle. The form commonly used is a triangular prism of glass. A good contrivance for delicate experiments may be made with two rectangular pieces of plate glass firmly set to form two sides of a triangular box which is to be filled with water or spirits of turpentine. The prism is essential in apparatus for decomposing light.

PRISONS AND PRISON DISCIPLINE. Penitentiary science, or the system of detaining, punishing, and reforming criminals, is of modern origin. The Scriptures contain references to prison houses and to the punishment of offenders. In Greece and Rome punishments were inflicted by loss of caste, of citizenship, and of liberty, banishment, and penal labor, which was sometimes performed on public works, in quarries, mines, &c. In the Roman empire there were houses, called *ergastula*, used chiefly for the punishment of criminal and refractory slaves. In Rome there still remains a prison, known as the Mamertine caves, consisting of several vaults or apartments. (See *ROME*, vol. xiv., p. 411.) The feudal barons had towers in their castles called *donjons*, whence is derived dungeon, for the confinement of their captive foes or refractory retainers. Sometimes the prison vaults were cut in the solid rock below the surface of the earth.—A movement for the amelioration of the wretched condition of English prisons and prisoners was begun by John Howard, whose investigations led to the enactment of two laws by parliament in 1774, one abolishing prison fees (which up to that time had been exacted from all prisoners) and the protracted

confinement of the prisoner until these were paid, the other providing for an improvement of the sanitary condition of jails. In 1777 appeared the first work of Howard on prisons, "The State of the Prisons in England and Wales." The works of Beccaria on crime and punishment appeared about the same time on the continent; and in England Sir William Blackstone, Mr. Bentham, and Mr. Eden entered upon the work of prison reform in earnest. The prisons were found to be in the most wretched condition, while the treatment to which the prisoners were subjected was demoralizing in the highest degree. In 1776 a prison was built at Horsham by the duke of Richmond under Howard's advice and coöperation, and was a marked improvement upon any prison then existing. In 1778 an act for the establishment of penitentiary houses was passed through the efforts of Howard, Eden, and Blackstone. The leading principles of the new system were that "if any offenders convicted of crimes for which transportation has been usually inflicted were ordered to solitary imprisonment, accompanied by well regulated labor and religious instruction, it might be the means under Providence, not only of deterring others, but also of reforming the individuals and turning them to habits of industry." There was much delay in carrying out the proposed reforms. In 1791 Jeremy Bentham published his "Panopticon, or the Inspection House," containing a plan for a model prison; but it was not till 1821 that the great penitentiary at Millbank on his model was completed, though it had been opened in 1817. It comprised six pentagonal structures radiating like the spokes of a wheel from a central hexagon, from which all the cells were visible. This prison was torn down in 1875. In 1842 was opened the cellular prison at Pentonville. Government convict prisons have also been established at Brixton, Portland, Chatham, Portsmouth, Parkhurst, Dartmoor, and Woking. The convict prison at Fulham is exclusively for females, who are also sent to Woking. Early in the present century Mrs. Elizabeth Fry commenced her mission to the female prisoners in Newgate; and in 1818 Mr. (afterward Sir T. F.) Buxton published an "Inquiry whether Crime and Misery are produced or prevented by the present System of Discipline." From this work it appears that, notwithstanding Howard's exposures, Mrs. Fry's revelations, and the developments made by the committee of aldermen of London in 1815, the abuses of Howard's time still continued, and had in many particulars increased, and that a radical and thorough change was needed. The hulks of men-of-war were for a time used as prisons, but have been abandoned. In the United States, the work of reform was begun in Philadelphia in 1776, and has been steadily carried on by a large number of philanthropists and publicists. Chief among these have been Louis Dwight, Roberts Vaux, one of the

founders of the cellular system, Edward Livingston, Francis Lieber, Elam Lynde, the founder of the Auburn system, Amos Pillsbury, for 40 years the head of the Connecticut state prison and the Albany penitentiary, and John W. Edmonds, the founder of the New York prison association. These are no longer living; but the work is still carried on by Dr. E. O. Wines, whose extended labors in behalf of prison reform are well known throughout the civilized world, by Sanborn, Brockway, Richard Vaux, and many others. In Europe the subject of penitentiary reform has been earnestly discussed in recent years, and reforms have been urged in all countries. Prominent among the leaders have been Sir Walter Crofton in Ireland; Mr. Crawford, Alexander Maconochie, Gen. Jebb, Matthew Davenport Hill, and Miss Mary Carpenter in England; Stevens in Belgium; Pols in Holland; De Metz, Béranger (de la Drôme), Bonneville de Marsangy, and Loysen in France; Obermaier, Varrentrapp, and Holtzendorff in Germany; Guillaume in Switzerland; Count Sollohub in Russia; and Beltrani Scalia in Italy. Various prison congresses have been held in Europe since 1845, when the first, proposed by Ducpétiaux, then inspector general of prisons in Belgium, was convened at Frankfort. The most important of these was the international congress proposed by Dr. Wines and held in London in 1872. A second international congress is to be held in Europe in 1877. A permanent commission for the study of penitentiary reform, organized by the congress of London, held sessions in Brussels in 1874 and in Bruchsal in 1875. Commissions for the revision of the penal code and prison reform have been at work recently in France, Italy, and Russia. In the United States national prison congresses were held in Cincinnati in 1870, Baltimore in 1872, and St. Louis in 1874. The leading principles which it is sought to introduce into prison management in all countries are thus epitomized by Dr. Wines: "Reformation of prisoners as a chief end to be kept in view; hope as the great regenerative force in prisons; work, education, and religion as other vital forces to the same end; abbreviation of sentence and participation in earnings as incentives to diligence, good conduct, and self-improvement; the enlisting of the will of the prisoner in the work of his own moral regeneration; the introduction of variety of trades into prisons, and the mastery by every convict of some handicraft as a means of support after discharge; the use of the law of love as an agent in prison discipline, to the exclusion, as far as may be, of the grosser forms of force; the utter worthlessness of short imprisonments, and the necessity of longer terms even for minor offences, when repeated; and the intellectual, moral, and industrial education of neglected, vagrant, and vicious children, this last being, in aim and essential features, an anticipation of the industrial school and

juvenile reformatory of our day." The reformation of the prisoner is sought primarily for the protection of society. A marked tendency of advanced American opinion on the subject of penal treatment is the centralization and unification of control of all the prisons of a state, and their correlation for preventive and reformatory ends. Under the law of 1873, all prisoners in Maine, except the boys in the state reformatory, are practically under one board of control. There is also a growing tendency toward the recognition of prenatal influences producing the criminal impulse and transmitting it from one generation to another, and of the existence of physical causes of disease and degeneracy. The prevalence of these views frequently induces great caution in inflicting retributive punishment. Indeed, in some states the abolition of definite term sentences is urged, as being necessarily vindictive in some degree, and the substitution of indefinite committal to custody until such observable modifications of character are wrought as give good hope of the criminal's reform.—The association of convicts day and night was formerly much practised, and still prevails to a limited extent in some prisons of Europe; but this plan is now generally condemned. Three systems are in use: 1, the separate or cellular, known also as the Pennsylvania or "individual treatment;" 2, the associate or congregate, also called the Auburn; 3, the Irish convict, or Crofton. Transportation was practised in Great Britain as early as 1619, when 100 convicts were sent to Virginia, and afterward small numbers were occasionally sent out and sold to the planters for 7 to 14 years, a practice often alluded to by Defoe and other writers; but the business was not conducted systematically till after 1718, when for a number of years as many as 2,000 convicts were annually transported. In 1786 it was determined to establish a penal colony in Australia, and the first cargo, of 880 convicts, was sent out in 1787, to Port Jackson, near Sydney. The convicts died by hundreds of fever on the passage out; or if they arrived they were unable to earn a subsistence, and perished of famine, or, to preserve life, adopted the savage habits of the native bush rangers. At length the influx of free settlers, the extensive sheep culture, and the building up of large towns, made their condition tolerable; while the grants of lands to the emancipists, as those who had served their time were called, and the plan of allowing tickets of leave, which in some cases shortened their term of punishment almost one half, soon gave to the convict settlers a predominating influence in the colony. This led to the organization among the free settlers of a party opposed to the system, and in 1840 transportation to South Australia ceased. It was maintained in Tasmania till 1853. In 1857 an act was passed abolishing transportation entirely as a means of punishment; but convicts sentenced to penal servitude might

still be sent beyond seas by order of the secretary of state. In 1867 transportation was altogether discontinued. Transportation to penal colonies in Guiana and New Caledonia is now a part of the penal code of France, which has also agricultural penitentiaries in the island of Corsica. Under the penal laws of Spain the punishment of fetters for life is undergone with labor in designated places in Africa, in the Canary islands, or beyond the seas. Transportation into penal colonies in Africa was adopted by Portugal in 1852, and is still practised. Italy has agricultural penal colonies in the islands of Gorgona, Capraia, and Pianosa, in the Tuscan archipelago, and also in the island of Sardinia. The penal code of Russia prescribes transportation with hard labor for life, or from 4 to 20 years, to Siberia, and beyond the Caucasus.—The foundation of the separate system, as it is now practised in this country and in Europe, was laid in Philadelphia in the latter part of the last century. The abuses attending the treatment of prisoners had been strongly condemned by a number of philanthropists in that city. Prisoners were associated together day and night, and made to work in the public streets. In 1790 a law was passed by the legislature to try the system of "solitary confinement to hard labor," which was soon after adopted in the Walnut street jail. In 1821 the legislature authorized the construction of the eastern penitentiary there, which was opened in 1829. The western penitentiary had been opened in Pittsburgh in 1827, and in both the separate system was adopted. It has been discontinued in the western, but in the eastern it is still maintained. This prison was visited by De Tocqueville, Beaumont, Demetz, Blouet, Mr. Crawford, inspector general of the prisons of England, and other foreign publicists, and was taken as the model of the great English prison of Pentonville, and of other prisons in Paris, Belgium, Holland, Germany, Sweden, Norway, Denmark, and other countries. The distinguishing features of the separate or cellular system are individual separation of the prisoners day and night during the entire term of their imprisonment, communication with the officials, visits and correspondence with persons outside under prescribed restrictions, individual walks in the open air, obligatory and remunerated work for the prisoners, and mental, moral, religious, and technical individual instruction. Not only is the association of convicts prevented, but even the opportunity of seeing one another. Each is kept in a separate cell, where he eats, sleeps, works, and passes the entire term of his imprisonment, except the time spent in exercise in the small yard attached to his cell. When he leaves his cell his face, except the eyes, is covered with a cap to prevent recognition. When religious services are held, the convicts in many prisons remain in their cells. In the Belgian prisons they can

see the priest, but not one another; in the eastern penitentiary they hear but do not see the preacher. In the cellular prison at Bruchsal, Baden, they leave their cells to attend religious services and to receive secular instruction, but with their faces covered; visitors are seen in a room assigned for that purpose. The advantages claimed for this system are that it prevents mutual corruption and other evil influences of the association of convicts, promotes the manhood and self-respect of the prisoner, especially after liberation, diminishes the chances of escape, admits a variation of discipline by affording an opportunity for the separate study and treatment of each prisoner, and in consequence of its repressive and reformatory efficiency permits a diminution of the period of imprisonment. Thus by the Belgian law of 1870 a sentence of one year, if to cellular imprisonment, may be reduced to 9 months, of 5 years to 3 years and 5 months, of 10 years to 6 years and 3 months, of 15 years to 8 years and 5 months, and of 20 years to 9 years and 8 months. Those sentenced to imprisonment for life can be compelled to pass only the first 10 years in separate confinement. In the eastern penitentiary in Philadelphia the prisoner is able by good conduct to reduce his sentence one month in each of the first two years, two months in each succeeding year to the fifth, three months in each following year to the tenth, and four months in each remaining year of the sentence. Chief among the objections urged against the system are that it wars against the social instinct in men, producing a morbid state of mind and increasing the percentage of insanity, and that it is more costly than the congregate system. In reply it is maintained that the first of these objections is not supported by statistics, while the increase in cost is balanced by the decrease in the duration of imprisonment. In the United States the separate system has met with little favor outside of Pennsylvania; in every other state the congregate plan has been adopted. In Europe, however, the former has many advocates. When adopted, it is generally applied in the case of short sentences with provision for abbreviation. It has received its best development in Belgium, where it prevails almost entirely, having been first tried in the prison of Ghent in 1835. The penitentiary of Louvain, which has about 600 cells, is regarded as the model cellular prison of Europe. The system prevails in a few of the French, Prussian, Austrian, Norwegian, Swedish, and Italian prisons. Denmark has one cellular prison for male convicts in Seeland; no person can be kept in isolation longer than three years and a half. In Baden sentences to hard labor and to imprisonment are served in cellular prisons, but such confinement cannot be extended beyond three years without the consent of the prisoner. The convict prison of Bruchsal is strictly cellular. Bavaria has one cellular prison for convicts and three for persons awaiting

trial; the former is at Nuremberg, and has a capacity for 400 men. In Holland the judge may sentence to separate or associated imprisonment, but the former must not exceed two years. The three great cellular prisons are in Amsterdam, with 208 cells, Utrecht, 186, and Rotterdam, 344. Many of the local prisons are also on the separate plan.—The congregate system was first adopted in the United States in the state prison of New York at Auburn. This, however, was not the origin of the system; for it had been practised as early as 1703 at the prison of San Michele in Rome, on the portals of which was inscribed: *Parum est improbos coercere pœna nisi probos efficias disciplina* ("It is useless to punish the bad without improving them by discipline"). An excellent prison of this kind was also opened at Ghent in 1775. Industrial labor, religious and scholastic education, abbreviation of sentence, participation in earnings, &c., were found by Howard in this prison when he visited it in 1775-6, and again in 1781. But soon afterward the plan of conducting the prison was changed by the emperor Joseph II., and its reputation for excellence was lost. The construction of the Auburn prison was begun in 1816. The plan of idle seclusion in separate cells was at first adopted, and it was not till 1824 that the congregate system was fully established by Capt. Elam Lynde. Under this system the prisoners labor in association during the day, take their meals either together or in their cells, and attend religious exercises in a body. Strict silence is enjoined upon the convicts. Communication may be held with the officers of the prison, and with visitors when permission is granted. The night is passed by the prisoners in solitary confinement in a small cell. It is asserted that this system is more economical than the separate, both because the original cost of construction is much less in consequence of the cells being smaller, and because associated labor is attended with greater profit. It is also said to be better adapted to the mental and bodily condition of the convict. It prevails extensively in Europe, and exclusively in the United States except in Philadelphia.—The distinguishing features of the separate and congregate systems are united in the Irish convict or Crofton system, which was introduced by Sir Walter Crofton into Ireland in 1854, where it has since prevailed with the most successful results; and it has been accepted by many, and especially American penologists, as the best penal system yet devised. Its origin is attributed to Alexander Maconochie, who had expounded and advocated the fundamental principles of the system before putting them into practice in 1840 at the penal colony under his charge on Norfolk island. Maconochie was recalled in 1844, and the former system of cruelty was reestablished there. M. Bonneville de Marsangy of France also proposed and published as early as 1846 a plan of penitentiary treatment embodying the

main features of this system. In perfecting a plan of penal treatment, Sir Walter Crofton had to deal with the three principles of secondary punishment (*i. e.*, by terminable imprisonment) generally recognized by penologists: 1, the deterrent principle, which by the application of pain is intended to impress the convict, as well as the community, with the belief that the profits of crime are overbalanced by its losses, thus subduing by fear the desire of the criminal to do wrong; 2, the principle styled by Bentham that of "incapacitation," which is designed to render the culprit incapable of committing crime by removing him from society to the prison; 3, the reformatory principle, by which the desire of the convict to do wrong is overcome. The union of these principles into one plan of treatment in order to attain the "twofold end of punishment, amendment and example," is the basis of the Crofton system. The term of imprisonment is divided into three stages, and is passed in three different prisons: Mountjoy prison in Dublin, which has a capacity for about 500 convicts; Spike island, in the harbor of Queenstown, which will accommodate 700; and Lusk, about 12 m. from Dublin, with accommodations for 100. The first stage continues eight or nine months in separate imprisonment in a cellular prison. The treatment here is made penal by a very reduced dietary during the first four months, meat being entirely withheld, and by the absence of interesting employment during the first three months, the convicts being occupied chiefly in picking oakum. Much time is spent in receiving religious and secular instruction, and each convict is taught the entire scope of the system of imprisonment he is undergoing, and how much depends upon himself. The controlling feature of the second stage is the system of marks, by which the classification is governed and the abbreviation of the sentence determined. There are four classes in the second stage, and the time spent by a convict in each class is determined, within certain limits, by the number of marks gained. The maximum number to be attained is nine a month, three each for good conduct, attention to school duties, and industry at work. Skill is not rewarded by marks. The convict must gain 18 marks in the third class to pass to the second, 54 in the second for promotion to the first, and 108 in the first before entering the advanced class. Thus, as he can acquire only nine marks a month, he must spend at least 2 months in the first class, 6 in the second, and 12 in the first. The time passed in the advanced class depends upon the length of the sentence. It must be at least 13 months when the sentence is five years, 53 when it is 10, and 93 when it is 15 years. During the second stage the convicts are employed in association, chiefly on public works. They do not receive any portion of their earnings, but are allowed certain gratuities, which are re-

ceived on release. The chief punishments are loss of marks, forfeiture of gratuities, withdrawal of privileges, and remanding to a lower class or to the cellular prison at Mountjoy. The most remarkable feature of the Crofton system is the third or "intermediate" stage, passed at Lusk. Here are no walls, or bars, or police, or armed watchmen. There is no physical restraint, no check on conversation, no prison garb. The prisoner is here in a condition of semi-freedom, a state of probation before liberation. The convicts are employed in groups upon the farm under the supervision of a half dozen unarmed warders, who generally work with them. There is nothing to prevent escape by day or night; but the desire to escape has been manifested very rarely. The mark system is discontinued. There are no punishments, but the convict may be remanded back to separate and solitary confinement at Mountjoy. The convicts hear frequent lectures, and attend the parish church in a body. The period of detention here varies with the length of the sentence; it is 6 months on a sentence of 5 years, 11 months on one of 10 years, and 16 months on one of 15 years. The object of the treatment is threefold: 1, by exposing the criminal to the ordinary temptations and trials of the world, to test his reform; 2, to afford a guarantee to the public that the reform is real, and that the convict may be trusted; 3, to supplement the previous discipline with a more natural training, and so by partial freedom to prepare the prisoner gradually for full liberty. The same principles of progressive classification are applied to females, for whom there is a separate prison during the first stage at Mountjoy, and provision for the associated labor of the second stage in the same prison; while the intermediate or final stage is passed in "refuges." The amount of reduction which a convict may effect in the duration of his imprisonment is determined by his conduct and industry at Spike island. Suppose he is sentenced for five years: what is the maximum reduction within his reach? He must pass 8 months at Mountjoy, 33 months at Spike island (2 months in the 3d class, 6 in the 2d, 12 in the 1st, and 13 in the advanced) and 6 months at Lusk, making 41 months in ordinary imprisonment, and 6 in semi-confinement. His period of detention therefore is 3 years and 11 months, and he is restored to liberty on a ticket of license 13 months before the expiration of his sentenced term. In like manner he may reduce a sentence of 10 years to 7 years and 8 months, and one of 15 years to 11 years and 5 months. When the convict has passed through the system of penal treatment above described, and secured an abbreviation of his term of imprisonment, he is not restored to unconditional freedom, but is liberated upon a ticket of license. He is subject to the supervision of the constabulary, to whom he must report at regular intervals for registration;

and if he fails to perform the conditions of the license, he may be remanded to prison for the remainder of his term of sentence. The nearest approach to the Crofton system outside of Ireland is found in England, but without its crowning feature in the intermediate stage. It is regarded with favor in Switzerland, where some of its features have already been adopted. Its introduction into the United States, with certain modifications, is recommended by high authorities, but is opposed by others as not being adapted to a government composed of separate states. The number of inmates in the Irish convict prisons during the year ending March 31, 1874, with the average cost of their support, was as follows:

PRISONS.	Average number of convicts.	ANNUAL COST PER PRISONER.	
		Gross.	Net.
Mountjoy, male.....	151	£54 8s. 6d.	£46 19s. 7d.
female.....	295	82 6 8	26 15 5
Spike Island.....	644	30 5 3	14 7 11
Lusk.....	40	68 1 9	39 8 0
Total.....	1,130	£36 6 11	£22 17 4

—In the United States there are as many systems of prison management as there are states. There is no national institution for the confinement of offenders against the national laws, who are consequently sentenced to the prisons of the several states. All places of confinement in the United States may be divided, according to their management, into municipal (town and city), county, and state prisons; and according to the grade of offence, into juvenile reformatories, houses of correction, and state prisons. In general each county has one, and some of them two or three jails. These as well as the city prisons are generally houses of detention, though in some of the county prisons a system of industrial labor, instruction, &c., is established. The county prisons are generally considered unsatisfactory either for detention before trial or for the imprisonment of offenders after conviction, and it is earnestly sought to provide something better in place of them. This want has given rise to the class of prisons called houses of correction, workhouses, and sometimes penitentiaries. Each of the 37 states has a state prison, except Delaware, which uses the county jails for the confinement of convicted felons. New York and Indiana (including that for women) have three each, and Pennsylvania and Iowa two each, making 43 state prisons in the United States, exclusive of the convict prisons in the territories. The chief prison officers are usually appointed by the governor to hold office during good behavior; in New York they are appointed by the elective board of three prison inspectors. Most of the states have such boards, generally appointed by the governor. The New York prison association is also authorized to inspect all the prisons of

the state. Many of the prisons contain from 300 to 500 cells. The largest are in New York, that at Auburn having 1,292 cells, and Sing Sing 1,200. The Ohio penitentiary at Columbus has 1,110 cells, and that of Illinois at Joliet 1,000. These institutions, however, as well as those in other states, frequently receive a greater number of convicts than they have cells. The total number of cells in all the state prisons is about 16,000. Some of them are intended for two or more prisoners. Their average dimensions are 8 ft. long, 4½ ft. wide, and 7½ ft. high, giving for the average contents of each about 240 cubic ft. Those in the Pennsylvania prisons and the prison for women in Indianapolis are much larger; in those of Illinois, Indiana, Iowa, Massachusetts (a portion), New York, Ohio, and some other states, they are smaller. Penal or "hard" labor, as by the treadmill, the crank, the shot drill, &c., which has been so common in English prisons, hardly exists in the United States. Here the labor is industrial, of which almost every kind is practised, according to the requirements and opportunities of the locality. The contract system of labor prevails exclusively in 19 of the state prisons, the leasing system in 6, state management exclusively in 9, and a mixed system in 7. Under the contract system the labor of the convicts is generally let at a fixed sum per day, which is often very small. Penologists find objections to this system on reformatory grounds, but it is generally less expensive to the government than the management of prison labor by the officers. In large prisons it is regarded by many as indispensable; but it is thought that it can be safely dispensed with in prisons containing fewer than 200 convicts. According to the report of the national prison association, the total income of 29 convict prisons in 1873 was \$1,413,073, including \$1,328,882 earnings from labor and \$84,191 from other sources, chiefly for the board of United States prisoners. The average earnings for each of the entire prison population amounted to \$121; for each engaged in productive labor, \$173. The average per capita cost of the convicts was \$172. Of the 29 states that reported, 12 showed an excess of earnings over the total current expenses, including salaries, as follows:

STATES.	Average No. of prisoners.	Total current expenses including salaries.	Prisoners' earnings from labor.	Total income.
Maine.....	146	\$29,811	\$35,076	\$35,856
New Hampshire.....	82	18,067	22,106	23,679
Vermont.....	80	18,312	14,380	14,380
Massachusetts.....	578	117,918	181,957	141,845
Rhode Island.....	74	8,196	10,991	11,996
Connecticut.....	180	24,941	25,572	26,452
Maryland.....	587	65,466	71,104	71,104
Ohio.....	910	152,164	171,451	174,450
Indiana (Michigan City)...	354	49,748	50,069	67,465
" (Jeffersonville)...	395	66,506	65,650	67,088
Michigan.....	618	90,276	88,087	91,065
Mississippi.....	288	43,355	43,880	44,230

The total excess of earnings over expenditures in these states was \$85,588; total number engaged in productive labor, 6,544. The state prisons of Illinois, Iowa, Louisiana, and New Jersey are also self-sustaining. Since 1873 the expenses have exceeded the earnings in the Massachusetts prison. The total ordinary expenditures of all the state prisons were reported at \$3,045,789. The most economically administered prisons were those in North Carolina, where the average cost per capita was \$89; Virginia, \$99; and Rhode Island, \$101. The most expensive were Nebraska, \$454; Nevada, \$383; South Carolina, \$376; Minnesota, \$352; Wisconsin, \$313; Oregon, \$312; Florida, \$302; and Arkansas, \$300. In Connecticut it was \$128; Indiana, Michigan City \$140, Jeffersonville \$170; Maine, \$200; Massachusetts, \$193; New York, Auburn \$161, Sing Sing \$274; Ohio, \$167.—Disciplinary agencies in prison management may be divided into two classes, deterrent and reformatory, the former comprising punishments and the latter rewards, secular and religious instruction, industrial training, &c. Extreme physical punishments, by the lash, rod, strait jacket, stocks, shackles, handcuffs, ball and chain, and shower bath, are still found in the codes, if not the practice, of many states. These punishments are applied only as a last resort, and in many of the states mentioned are rarely, and in some perhaps never, put into practice. In many of the other states they are expressly forbidden by law. Public whipping still exists in Delaware. The most common punishments are the dark cell with reduced rations, deprivation of privileges, &c. The rewards are usually petty privileges, as the use of tobacco, a light in the cell, and better food. In a few prisons the convict is allowed a share of his earnings, and in many by good conduct may abbreviate the term of his imprisonment. By recent laws of Ohio and some other western states, the convict will be restored to citizenship if he passes the entire period of his sentence without violating the rules of the prison. The pardoning power is generally vested in the governor; civil rights are usually restored by pardon. The percentage of prisoners pardoned in 1873, exclusive of those discharged by commutation, was 5½. Most of the prisons have chaplains; in nearly all weekly religious services are held, and many have Sunday schools and frequent prayer meetings. The provisions for the intellectual improvement of prisoners are very inadequate, but have been considerably enlarged in recent years. Libraries are common, 83 prisons in 1873 reporting 50,663 volumes, an average of 1,535 to each; and in some prisons the convicts have the benefit of schools, individual instruction in their cells, and lectures. Secular instruction is regularly afforded in the prisons of California, Illinois, Indiana, Kansas, Kentucky, Massachusetts, New York, New Hampshire, Oregon, Pennsylvania, Rhode Island, and Wisconsin. In some of these states a

school is held once a week; in others two to five evenings a week. The regulations concerning correspondence and visits to prisoners vary greatly in different prisons. In some the frequency of both is optional with the warden; in others the convict is allowed a letter and a visit only once in three months. Little has been done in the United States toward establishing special prisons for women. The best institution of this class was opened in Indianapolis in 1873; it is a state institution, and has penal and reformatory departments. New York has a prison for females at Sing Sing, under the same administration with the male prison, and the legislature of Massachusetts has authorized the construction of a reformatory prison for women. The state prisons of the United States, with the number of cells and average number of prisoners in 1873, as reported by the national prison association, were as follows:

STATE.	Where situated.	Number of cells.	Average number of prisoners in 1873.

—There is a class of prisons in the United States, generally called houses of correction, work-houses, and sometimes penitentiaries, which hold a middle place between the municipal or county jail and the state prison, and are intended for the treatment of those convicted

of lighter offences, though felons are sometimes confined in them. These institutions form an important link in any true prison system, and from them have sprung many of the practical reforms of prison administration wrought in America. They are preventive of crime by their wise and thorough treatment of misdemeanors who are as a rule developing into felons. They are commonly managed and maintained by the county or city, but some receive state convicts. Most of them have systems of discipline, labor, instruction, &c., similar and sometimes superior to those of higher prisons. Institutions of this kind are maintained in Massachusetts, Rhode Island, New York, Pennsylvania, Michigan, Ohio, Wisconsin, Kentucky, Missouri, California, and perhaps some other states. New York has six under the title of penitentiaries. The most noted and best managed of these institutions are the Albany and the Monroe county penitentiaries in New York, the former brought to its high degree of excellence by Amos Pillsbury; the Detroit (Mich.) house of correction, organized and conducted during the first ten years of its existence by Z. R. Brockway; and the Allegheny county (Pa.) workhouse at Claremont, under the superintendence of Henry Cordier. In each of these there is an excess of earnings from the labor of the prisoners over the expenses of the institution; and each has excellent schools. The house of correction in Boston, Mass., is sometimes self-sustaining. Another prison of this class, called the state house of correction, is in process of construction (1875) at Ionia, Mich.; also one at Elmira, called the New York state reformatory. The Albany penitentiary is one of the principal places of confinement for United States prisoners. For institutions for the treatment of juvenile offenders, see REFORMATORIES.—The system of penal treatment in England in many respects is similar to that of Ireland. The intermediate or probationary stage, which forms so important a feature in the Irish system, is not found in the English, except in the treatment of female convicts. All convicts sentenced to penal servitude are required to pass through three principal stages. The first is passed at Pentonville, and continues for nine months, during which the prisoner spends his entire time, excepting that devoted to prayer and exercise, alone in his cell, working at some industrial or remunerative employment. The treatment here, especially the diet, is sternly penal; but the convicts have the use of books, and, besides receiving religious instruction, are taught reading, writing, &c. From here the prisoner is removed to one of the other convict prisons, where he works in association, but spends the rest of his time in a separate cell. The prisoners are chiefly employed on public works, farming, clearing and reclaiming land, &c.; but in some of the prisons boot making, tailoring, and other indoor employments are carried on. The convicts

* Large dormitory.

† Recently constructed.

are divided into four classes, the higher classes having privileges not found in the lower. Promotion is determined by marks, which are given not for good conduct, but for industry alone. In addition to the privileges acquired by promotion to a higher class, the prisoner may gain a remission of about one fourth of his sentence, or if a female, about one third. The chief advantages offered by the higher classes are more frequent communications by visit or letter with friends, more freedom for exercise on Sundays, and higher gratuities of money to be paid on the prisoner's discharge. Convicts receive no share of their earnings, but each is allowed sufficient money on discharge to maintain himself while seeking employment. There is no extra reward for good conduct; but bad conduct is punished by degradation to a lower class and the loss of privileges gained by industry, as well as by solitary confinement, reduction in diet, and corporal punishment. Only the governor and director have the power to punish, under limits defined by the secretary of state. Unusual punishments are prohibited; but whipping is practised, and chains, handcuffs, or means of special restraint may be used in certain defined circumstances and under strict regulations. The privilege of petitioning the secretary of state is given to every convict. When the prisoner has secured a remission of a portion of his sentence, he is liberated on a ticket of license. He is now subject to police surveillance, and will be remanded to prison for a violation of the conditions of the license. Formerly it was the custom to transport convicts thus conditionally liberated on a ticket of leave; but since 1867 this practice has been discontinued. The same course of treatment is applied to females; but they may earn a larger proportion of remission, viz., one third; while those whose reform appears to be complete may pass the last six months of their imprisonment in "refuges" established and managed by private effort, assisted by contributions from the government. Of these there are three: the Carlisle memorial at Winchester, the Eagle house at Hammersmith for Roman Catholics, and the Westminster memorial at Streatham. The number of inmates of the English convict prisons during the year 1873 was as follows: Brixton, 504; Chatham, 1,682; Dartmoor, 939; Fulham (females), 277; Millbank, 1,122 (908 males, 214 females); Parkhurst, 552; Pentonville, 911; Portland, 1,586; Portsmouth, 1,282; Woking, 1,390 (718 males, 672 females); total, 10,245. The gross annual expenses were £342,158, and the net earnings of the convicts £220,490; balance, £121,668, making the net cost of supporting each convict during the year £11 14s. 6d. The earnings of the convicts exceeded the expenditures at Chatham and Portsmouth, and very nearly equalled them at Portland. The extensive government works at these points, the sea walls, docks, &c., including both the skilled and un-

skilled labor, have been constructed by convicts.—France has six classes of prisons: 1, the penal colonies of Cayenne (Guiana) and New Caledonia; 2, central prisons (*maisons de force et de correction*), of which there are 16 for men and 7 for women, corresponding to the state prisons in the United States; 3, departmental prisons, about 400 in number, designated also as houses of arrest, of justice, and of correction; 4, establishments for the correctional education of juvenile delinquents; 5, chambers and depots of safe keeping; and 6, prisons for the army and navy. The chief sentences, besides death, are hard labor for life or for a term of 5 to 20 years, reclusion for 5 to 10 years, and simple imprisonment for from 6 days to 10 years. Sentence to hard labor is attended with civil degradation and civil death, the property of the culprit being under the control of a guardian. After the expiration of a sentence to a limited term of hard labor, the criminal during the remainder of his life is under the supervision of the police. Except women and men 60 years of age and over, who undergo imprisonment in the central prisons, persons sentenced to hard labor are transported to one of the penal colonies. If the sentence is for less than eight years, the convict must remain in the colony after the expiration of his punishment during a period equal to the length of his sentence; if the sentence is eight years or more, such residence is made perpetual. The transportation of women is authorized by law in view of marriages to be contracted with the convicts in the colony after liberation; some women have been thus sent to Cayenne, but a majority undergo imprisonment in the central prisons of France. A sentence to the punishment of reclusion deprives the criminal of civil rights. Every person so sentenced is confined in a central prison and employed in labor, which may be in part applied to his own benefit. Simple imprisonment is a correctional punishment, which however may work partial or entire loss of civil rights. In case of relapse, the duration of the punishment may be doubled. If the sentence is for more than a year, the culprit is sent to a central prison; if a year or less, to a departmental prison. The product of the prisoner's labor goes partly to the prison and partly to secure for himself, if deserving, certain privileges, or to form a fund to be used when discharged. Houses of arrest, of justice, and of correction are usually three departments of the same prison. Besides the punishments here described, the penal code recognizes that of deportation, or transportation for life to a place without the continental territory of the republic, upon pain of sentence to hard labor if the offender return; and detention for from 5 to 20 years in one of the French continental fortresses. The cellular system does not prevail in any of the central prisons; the convicts are here employed together in workshops during

the day, with cellular separation at night. A few of the departmental prisons are cellular, but even in these the strict separate system is not practised. Three prisons in Paris, however, are constructed and conducted on the cellular plan: Mazas, a part of La Santé, and La Petite Roquette; the last named is a prison for persons under 16 years of age and persons sentenced to an imprisonment not exceeding six months. The law of May, 1875, provides that persons awaiting trial shall be confined in separate cells, subjects those sentenced to 12 months' imprisonment or less to solitary confinement, and gives those with longer sentences the privilege of choosing separate confinement. Penal as distinguished from industrial labor does not exist in the prisons of France. Industrial labor is obligatory upon those serving sentences, and optional with the arrested and the accused. Extensive workshops are organized in the central prisons. In the male central prisons about 50 or 60 industries are carried on, the principal of which are weaving, tanning, and the manufacture of boots and shoes, buttons, hosiery, locks, and hardware. Three of the central prisons are "agricultural penitentiaries," or colonies in the island of Corsica where the convicts are employed in agricultural work. Sewing is the chief industry in the central prisons for females. The contract system of labor prevails in most of the prisons, but in several important establishments the industries are managed directly by the state. Convicts are allowed a portion of their earnings, being in the central prisons from three tenths to five tenths, according to the grade of the sentence. A portion may be used by the convict while in prison, and the balance is reserved till his discharge. The prisoners contribute about 50 per cent. of the cost of maintenance in the central, and about 17 per cent. in the departmental prisons. A few of the central prisons are self-sustaining or nearly so. The more important prisons are generally provided with chaplains, schools, and libraries; but only about 12 to 15 per cent. of the population in the prisons for males, and 5 to 8 per cent. in those for females, are admitted to the schools. Corporal punishment is prohibited in all prisons.—All the prisons of Belgium are under the jurisdiction of the minister of justice, and are subject to the supervision and inspection of commissions. Nearly all are conducted on the separate plan. There are three general classes: houses of correction, houses of reclusion, and convict prisons. In the first are confined prisoners sentenced to simple imprisonment for terms of 8 days to 5 years; in the second, those sentenced for from 5 to 10 years; and in the third, those sentenced to hard labor for life, from 10 to 15 years, or from 15 to 20 years. Industrial labor prevails in all prisons, penal in none. The labor is directed in part by the government, and in part is awarded to special contractors, preference being given to the latter plan. A sys-

tem of apprenticeship prevails, by which prisoners are taught various trades. The prison industries are varied and extensive. The prisoners receive a portion of their earnings, and rewards for good conduct, including reduction of sentence. Every prison with 50 or more inmates is provided with a school or a teacher, and school attendance is generally obligatory. Libraries are found in all prisons. The three great central or convict prisons of Belgium are those of Louvain, Ghent, and Antwerp.—All the prisons of Prussia are subject to a central authority, the large penitentiary establishments or central prisons being under the minister of the interior. There are 29 prisons exclusively for hard labor, 15 for imprisonment and simple detention, and 11 of a mixed character. The capacity of all is about 26,500. In 47 there is an aggregate of 3,247 cells for solitary imprisonment by day and night; but in only one of these is the separate system exclusively adopted; in the other 46 the cellular and the congregate systems both exist. The punishments prescribed by the penal code are hard labor, simple imprisonment, imprisonment in a fortress, and detention for minor offences. Sentence to hard labor may be for life or from one to 15 years. It subjects the prisoner to compulsory labor without restriction, both inside and outside the prison, and disqualifies him from serving in the army or navy, or in any public office. The judge may add civil degradation. In simple imprisonment, limited to five years, the convict cannot be compelled to work outside of the prison, or at occupations not in accord with his capacity or previous social condition. If the sentence is for three months or more, the judge may add civil degradation. Prisoners sentenced to hard labor or to imprisonment may be liberated provisionally at the expiration of three fourths of their sentence, provided they have been at least a year in confinement. Imprisonment in a fortress may be for life or for a term of years, not exceeding 15. The punishment is simply privation of liberty. The chief classification of prisoners in Prussia is the separation of the young from the old. Penal labor does not exist. Industrial labor comprises not less than 50 different trades carried on by men and 10 by women. The contract system prevails almost exclusively; the labor of the prisoners being let out, not to a few general contractors, but each industry to a special contractor. Prisoners are allowed a variable portion, not exceeding one sixth, of the product of their labor, to be used partly while in confinement and the balance after release. Among the punishments permitted is castigation in the case of men, limited to 30 lashes, and only when authorized by the director of the prison at the request of the superior officers, including the chaplain and surgeon. Chaplains, all forms of worship, schools, and libraries exist in all important prisons. About 15 per cent. of all the prisoners receive scho-

lastic instruction; those without trades must serve an apprenticeship. The prison libraries comprise upward of 150,000 volumes, about one half religious.—In Cisleithan Austria all prisons are under the jurisdiction of the ministry of justice; matters of minor importance, however, are intrusted to the local and intermediate authorities. Since 1867 there has been an inspector general of prisons. There are 18 prisons (12 for males, having in 1872 about 9,000 inmates, and 6 for females, with 1,500 inmates) for persons sentenced to more than one year of imprisonment; 62 for those sentenced to less than one year, which are also used for persons convicted of lighter offences; and prisons of the district courts for minor offences. Separate prisons are used for men and women. Until recently only the associated system of imprisonment existed, and it now prevails in nearly all the prisons. The convicts are classified in groups of 6 to 30, day and night, and are allowed to converse together except when at work. All prisons constructed since 1867 have been so arranged that associated imprisonment may be combined with cellular. Provisions for cellular treatment are found in the prisons of Gratz, Stein, Karthaus, and Pilsen. By the law of April 1, 1872, cellular imprisonment is limited to three years, with the provision that after three months of isolation two days passed in a cell are to be reckoned as three in the term of the sentence. In all prisons where the collective system prevails, a classification of prisoners is maintained in the dormitories, based on the age, education, state of mind, and former life of the convict, and the kind of crime committed. There is no way in which a convict may secure an abbreviation of his sentence except by being recommended for pardon to the emperor. Penal labor does not exist; a wide range of industries are carried on within, and some without, the prisons. The contract system is preferred where suitable contractors can be found; otherwise the industries are managed directly by the state. Convicts are entitled to a share of their earnings, to be used partly while in prison and partly after release. If the prisoner has property, it is liable for the cost of his imprisonment. Trades are taught to the unskilled. Corporal punishment is not practised. The severest punishments are chains, diminution of food, hard bed, isolated confinement, and dark cell. Banishment after the expiration of the sentence is recognized by the penal code. The prisons are generally provided with chaplains, schools, and libraries, though the last are of recent origin. School attendance is obligatory upon convicts of a suitable age. Political prisoners are absolved from compulsory labor and from wearing prison clothes.—In Switzerland most of the cantons prescribe three kinds of imprisonment: reclusion, perpetual or temporary detention in a house of correction, and simple imprisonment. Many of the cantons are introducing

important reforms into their prison systems, including progressive classification and provisional liberation. In the penitentiary of Neuchâtel, which has an average of 80 inmates, many of the features of the Crofton system have been adopted. The excellent system of discipline, labor, rewards, education, privileges, &c., adopted here by Dr. Guillaume, the director, has made this one of the model prisons of Europe.—The penal system of Italy is in a state of transition. The new code retains the death penalty, and prescribes as secondary punishments the *bagnio* for life (*ergastolo*), reclusion, and relegation. As a general rule *ergastolo* must be passed in one of the islands in continual separation for the first ten years, and afterward in congregate imprisonment. Sentences to reclusion and relegation, which are penalties of temporary duration, are to be served upon the congregate plan. Not fewer than 3,000 convicts are engaged in agricultural work, and 1,500 employed by private contractors or municipal bodies in the construction of ports and roads, in collecting and transporting salt from the mines of Cagliari and Portoferraio, in working iron mines, in masonry, and in other outdoor occupations. At the penal settlement of Cagliari much attention is given to the rearing of the silkworm, and at Alghero the culture of tobacco is a prominent industry. More than 1,000 prisoners are employed at the three agricultural colonies on the islands of Pianosa, Gorgona, and Capraia, in the Tuscan archipelago, chiefly in the cultivation of vines, olives, and cereals. The prisoner is entitled to a share of the product of his labor. He is required to attend school, where among other things he is taught the science of agriculture. The agricultural colonies are intended for those convicts who have been sentenced to reclusion, relegation, or simple imprisonment, and who have distinguished themselves in the penal establishments by good conduct.—In nearly all the countries of Europe efforts are made to aid liberated prisoners by securing for them employment and protection. This work is generally done by prisoners' aid or patronage societies, aided sometimes by the government. In some instances direct efforts are made by the government in behalf of discharged convicts. The Netherlands society for the moral amelioration of prisoners, both before and after discharge, has its seat in Amsterdam, with as many as 40 branches in different parts of the country. Denmark has prisoners' aid associations in the vicinity of each of its four great prisons. In England much importance is given to aiding convicts after discharge, and 34 societies have been established for this purpose. A semi-official character is given to them by the fact that they hold in trust the gratuities allowed by law to discharged convicts. Prisoners are also placed for a limited time after discharge under the surveillance of the

police. More than half of the male convicts discharged in 1873 applied to prisoners' aid societies, and more than three fourths of the females went to such societies or refuges. In the United States the organizations for aiding liberated prisoners are few. Massachusetts has an official agency. The other most efficient organizations are the New York prison association, the Philadelphia prison society, the Maryland prisoners' aid society, and the California prison commission. The prison association of New York was incorporated by the legislature in 1844; it is authorized to visit and inspect all the prisons of the state, and makes annual reports to the legislature. It has agents in all parts of the state to look after the interests of prisoners in confinement, and to aid them after discharge with money, board, clothing, tools, transportation, employment, &c. About 1,500 discharged convicts were aided by this association in 1874.—The marked lack of uniformity in the returns made by different countries renders their criminal statistics only approximately useful for purposes of comparison. A computation made by Beltrani Scalia, on returns from Belgium, Denmark, Holland, Italy, Saxony, and Sweden, shows about one half of the entire prison population of those countries to be illiterate. According to recent returns, the percentage of those who could not read on entering prison was 56 in Austria, 49 in Belgium, 57 in France, 4 in Baden, 12 in Bavaria, 17 in Prussia, 60 to 92 in Italy, about 40 in the Netherlands, and 30 in Switzerland. In Ireland 22 per cent. both of males and females were illiterate. In Austria 8 per cent. of the male and 24 per cent. of the female convicts had no trade on entering prison; in Belgium the percentage for both sexes was 60 to 70; in France, 5 per cent. among males and 12 per cent. among females; Baden, 40 per cent.; Bavaria, 3; Prussia, 5; the Netherlands, 25; Sweden, 90; Switzerland, 50; Ireland, 35. In Belgium and England, about 12 per cent. of the prison population are females; in Baden, 15; in Bavaria, 20; in France, 19; in the Netherlands, Prussia, and Sweden, about 18; in Norway, 24; in Russia, 10; in Switzerland, 20. The proportion of recidivists, or those who after imprisonment relapse into crime and are returned to prison, is reported at about 59 per cent. among men and 54 per cent. among women in Austria, 78 per cent. in Belgium, 20 in Baden, 30 in Bavaria, 42½ in France, 18 to 28 in Italy, 25 to 28 in the Netherlands, 60 to 70 in Prussia, 19 to 45 in Sweden, and 36 in Würtemberg. More than 18 per cent. of the sentences to penal servitude in England, Wales, and Scotland during the four years ending Jan. 1, 1874, were reconviictions. It is stated that nearly 70 per cent. of the recidivists in Belgium were those who had been confined in the congregate prisons. Of those committed to convict prisons in the United States in 1873, 21 per cent. were minors and 67 per cent. under 30 years of age; 75 per cent. were of native

and 25 of foreign birth. Thus, while about 17 per cent. of the total population of the United States are foreigners, not less than a fourth of the criminal population are foreigners. In the northern and especially the eastern states, where there is a larger foreign element in the population, the percentage of foreign convicts is much larger than that given above. Thus in Massachusetts it was 55 per cent., Minnesota 42, New York 39.5, California 39, New Jersey 37, Indiana (males) 32, and Michigan 30. About one sixth of the prison population are women. In the southern states a large proportion of the convicts are colored; 48 per cent. were illiterate, and 70 per cent. had not learned a trade; 40 per cent. admitted intemperate habits, and 39 per cent. more claimed to be moderate drinkers, but acknowledged occasional intoxication, leaving only 21 per cent. claiming to be strictly temperate.—The most satisfactory information on the penal systems of Europe and the United States may be found in the volume of transactions of the London congress (London, 1873), and in the three reports of proceedings of the three congresses held by the national prison association of the United States. Annual reports have been issued by the prison association of New York since 1844, and valuable information and statistics relating to crime and the treatment of criminals are contained in the "American Journal of Social Science," of which seven numbers had been issued in 1874; in the reports of state boards of charities, which are organized in several of the states; and in the reports published by the various penal and reformatory institutions of the United States. The general principles of penal treatment and legislation are expounded in the works of Howard, Beccaria, Bentham, Edward Livingston, Francis Lieber, and others. Among more recent publications are: "Crime, its Amount, Causes, and Remedies," by Frederic Hill (London, 1855); "Suggestions for the Repression of Crime," by M. D. Hill (London, 1857); "On Cellular Separation," by W. Parker Foulke (Philadelphia, 1861); "Our Convicts," by Mary Carpenter (2 vols., London, 1864); *De l'amélioration de la loi criminelle*, by Bonneville de Marsangy (2 vols., Paris, 1864); *Kritische Untersuchungen über die Grundsätze und Ergebnisse der irischen Gefängnisskunde*, by Baron von Holtzendorff (Berlin, 1865); *Des progrès et de l'état actuel de la réforme pénitentiaire, et des institutions préventives aux États-Unis, en France, en Suisse, en Angleterre et en Belgique*, by Ducpétiaux (3 vols. 18mo, with plates, Paris and Brussels, 1867); "History of the Albany Penitentiary," by David Dyer (Albany, 1867); *Sul governo e sulla riforma delle carceri in Italia*, by Martino Beltrani Scalia (Turin, 1867); "Brief Sketch of the Origin and History of the State Penitentiary for the Eastern District of Pennsylvania at Philadelphia," by Richard Vaux (Philadelphia, 1872); "The Crofton Prison System," by Mary Carpenter (Lon-

don, 1872); *La question pénitentiaire*, by Robin (Paris, 1873); "Causes of Criminal Recidivants and their Means of Prevention," by Olivaerona (Stockholm, 1873); "Penitentiary Studies," by Don P. Armengol y Cornet (Barcelona, 1873); "Swiss Prison Discipline," by J. K. Kühne (St. Gall, 1873); "Works of Edward Livingston on Criminal Jurisprudence" (2 vols., New York, 1873); "Report on the Working of the Separate System of Imprisonment in Holland," by De Vries (the Hague, 1874); "National Education and Punishments," by C. B. Adderly (London, 1874); *Les établissements pénitentiaires en France et aux colonies*, by Viscount d'Haussonville (Paris, 1875); and "Memorials of Millbank and Chapters in Prison History," by Arthur Griffiths (2 vols., London, 1875). The *Rivista di disciplina*, edited by Beltrani Scalia, inspector general of Italian prisons, and devoted to penitentiary science, is published monthly in Rome.

PRISREND, or **Perserin**, a town of European Turkey, capital of a vilayet of the same name in northern Albania, on the Rieka near its confluence with the Drin, 75 m. E. of Scutari; pop. variously estimated at from 20,000 to 48,000. It is built at the foot of a mountain, which is commanded by a castle, where the governor resides; a Greek bishop also resides here. It is chiefly noted for its manufacture of firearms and extensive traffic.

PRIVAS, a town of Languedoc, France, capital of the department of Ardèche, 70 m. S. of Lyons; pop. in 1872, 7,836. It is situated on a steep ridge near the junction of the Ouvèze and Mézayon, and contains a prefecture with a park, a small geological museum, a college and primary normal school, and manufactories of silk and other goods. It was a stronghold of the Huguenots, with an almost exclusively Protestant population. A synod of all French reformed churches was held here in 1612. Louis XIII. exterminated the Protestants in 1629, and razed the fortress in which they had taken refuge.

PRIVATEER, an armed private vessel which bears the commission of a state to cruise against the commerce of its enemy. When one sovereign has duly declared war against another, all the subjects of the former are enemies of all the subjects of the latter. From this principle of the law of nations follows the unquestionable corollary, that no citizen of one of the belligerent states can complain of the hostile acts of any citizen of the other. Therefore, as far as absolute international rights are concerned, it makes no difference whether a depredation or capture by a subject of the enemy has been expressly sanctioned by his sovereign. The universal practice of nations, however, condemns all unauthorized hostilities; and a capture or other hostile act without the sanction of a competent sovereign power, although, strictly speaking, it would not be piracy, yet would be so much like it, or so irregular and odious, that it would un-

questionably provoke the severest treatment at the hands of an enemy against those who engaged in it. Yet, though unauthorized capture of enemy property is no offence under the law of nations, it is an infraction of the public law of the captor's own state. For the universal rule is that, except in self-defence, only those subjects may take part in hostilities who are thereto expressly or constructively authorized by their sovereign. But the sovereign may, if he will, avail himself of the private vessels of his subjects by commissioning them to seize the merchant ships of the enemy. These commissioned private ships or privateers are in naval warfare much the same as the volunteer corps are in the land service. In both cases the commissions proceeding from the sovereign make those who bear them the instruments and servants of the state. On the sea it is the letters of marque which give that interest in the prize which is the inducement to engage in the service. For, primarily, all prizes vest in the state, and it is the commission alone which, under the municipal regulations of each state, defines the proportion of the captured property and the other rewards which shall fall to the privateersman. (See PRIZE.) To guard against the excesses and abuses which are incident to privateering, it has been subjected to various restrictions. Some states have regulated the composition of the crews, and have forbidden all cruising in the rivers or along the coasts within the sea line of the enemy. Generally commissions are granted on condition that the rights of neutrals shall be respected, and that belligerent rights shall in all cases be enforced according to the rules of war; that prizes shall be brought for adjudication before the proper tribunal; and that the whole conduct of the cruise shall be confined to the instructions of government. Bonds are taken for the due performance of these engagements, and owners and officers are subjected to penalties for the violation of them.—Privateering may be regarded in two aspects, or rather it may be said that there are two kinds of privateering, one of which is far more legitimate and defensible than the other. The former of these kinds is that in which the citizens of one of the states at war sail under their own flag against the enemy. They find employment in this way for the ships which during war must almost of necessity be withdrawn from trade; and they contribute very materially to the maritime strength of their state. The other and more odious form of privateering is that in which a neutral accepts a commission from one of two belligerents. Here the legitimacy of the practice is not so clear, at least so far as affects the neutral. He can certainly have no patriotic motive in accepting such a commission. Such a motive is rare probably even when the privateer sails under the flag of his own country; but then the country does really derive some benefit from the service. In the case supposed, the

neutral is a sort of legalized pirate, and so indeed he is regarded by those conventions and treaties which, in condemnation of this abuse of the international laws of war, almost all nations have entered into. Indeed, by such conventions and treaties, and by the municipal statutes by which nations forbid their subjects from equipping privateers or enlisting men for service in any foreign war, this species of privateering seems to be well nigh repressed. Not so the other. For nearly a century the expediency of its suppression had been at intervals elaborately discussed; yet in all that period but little advance had been made toward the settlement of the question. In 1856 the subject was revived at the congress which convened at Paris after the Crimean war, and the states there represented made mutual engagements to surrender the practice of privateering. The United States had early made an effort to abolish it. In 1785, and while he was negotiating with Prussia the treaty which was afterward concluded, Dr. Franklin wrote: "The United States of America, though better situated than any European nation to make profit by privateering, are, so far as in them lies, endeavoring to abolish the practice, by offering in all their treaties with other powers an article engaging solemnly that in case of future war no privateer shall be commissioned on either side, and that unarmed merchant ships on both sides shall pursue their voyages unmolested." Dr. Franklin procured the insertion of both these propositions in the treaty with Prussia. In the subsequent treaty of 1799 with that power, however, all provisions of this character were omitted. In 1792 the legislative assembly of France proposed that nations should agree by mutual conventions to abolish privateering and the seizure of private property on the ocean. The proposal met but little favor, and these practices were perhaps never more extensively carried on than during the wars which followed the French revolution. Again in 1824 the subject was revived, when, on our part again, it was urged upon the attention of the English government. But the plenipotentiaries, Messrs. Huskisson and Stratford Canning, declined to entertain the propositions of our minister, Mr. Rush, and he reported to government that in his opinion Great Britain was unwilling, under any circumstances, to accede to the abolition of private war upon the ocean. But a radical change in the sentiments of English publicists upon this question is indicated by the language of Lord Clarendon in 1854. In submitting to our ambassador, Mr. Buchanan, the declaration respecting neutrals which France and England afterward issued, the British minister advocated the abandonment of privateering, and expressed his condemnation of the practice as one which was "inconsistent with modern civilization." Mr. Buchanan replied; that under existing circumstances it did not seem possible for the United States to agree

to a surrender of the practice, unless the naval powers of the world would go one step further and consent to the abolition of all war against private property upon the ocean, as was already agreed upon as to private property upon the land. In answer to Mr. Buchanan's despatches, Secretary Marcy reminded the British government that the United States laws go as far as and even further than those of any other nation in prohibiting its subjects from entering into foreign privateer service; but he added that the country would not enter into any convention whereby it would preclude itself from resorting to its merchantmen in case of war. Finally the submission to our government of the declaration which was signed at Paris in 1856, by the plenipotentiaries of the chief states of Europe, called for a new consideration of the question. Besides provisions affecting the rights of neutrals, the convention contained an article which declared that privateering was abolished. The four points of the declaration were to be regarded as an entirety; they were to be binding only between those powers which assented to them; and the states that signed the convention undertook to invite the accession of those powers which were not represented at the congress. Most of the secondary states of Europe and America gave prompt adhesion to the articles of the declaration. The answer of our government to the declaration was, through Mr. Marcy, that the United States would accept the whole of it "in case the clause abolishing privateering were amended by adding that the private property of the subject or citizen of a belligerent on the high seas should be exempted from seizure by public armed vessels of the other belligerent, except it be contraband of war." This was declined, and there the matter was suffered to rest until the breaking out of the civil war in the United States in 1861, when Secretary Seward on behalf of the government, in view of the resolution of the confederate government to issue letters of marque to privateers, offered to assent to the declaration of Paris without the Marcy amendment; but this was declined by the governments of England and France if coupled with the condition that it was to be made applicable to the case of the Confederate States.

PRIVET (also called in England prim and primprint), a name formerly given to the primrose, and afterward unaccountably transferred to *ligustrum vulgare*, the generic name being the classical Latin one. It is a shrub which has been so much cultivated that in Europe its limits in a wild state are quite lost, but it is thought to be indigenous in England; it grows 6 or 8 ft. high, with long slender branches and opposite simple leaves, which in mild climates are evergreen, or remain until the new leaves appear. Its small white flowers, in compact panicles at the ends of the branches, have a four-toothed calyx and a four-lobed corolla, with a short tube; the fruit is a spheri-

cal, black berry, two-celled, with one or two seeds in each cell. It belongs to the same family with the olive, to which it is closely related. The privet is largely used in Europe for ornamental hedges, and was early in the century planted as a hedge in this country; but while

Privet (*Ligustrum vulgare*).

it has many qualities which adapt it to the purpose, it is here subject to a sudden blight or disease which has caused it to be abandoned. In the older states it has become thoroughly naturalized through the agency of birds. Planted in a shady place, it is a pleasing ornamental shrub, but if exposed to the full sun at noon, its flowers wither in a day; it grows well in the drip of deciduous trees, and is especially useful near the sea, where few ornamental plants flourish. The wood of the privet is hard and close-grained, and when of sufficient size serves for turning. The leaves and bark are bitter, and the smaller twigs are used in some parts of Europe for tanning leather. The young slender branches and shoots are employed like osiers for basket making and as withes. The berries afford a rose color which is used in tinting maps and prints, and dye green if alum is used as a mordant; they are also eaten by several kinds of birds. A greenish oil fit for lamps or to make soap is extracted from them by pressure. There are several varieties, such as the white-, yellow-, and green-berried, the narrow-leaved, and the variegated leaved. It is readily propagated by cuttings or by seeds.—The Japan privet (*L. Japonicum*) has large, thick, shining, evergreen leaves, which are broader than in the common species, and larger, pure white, slightly fragrant flowers. This and a variegated form of it are charming greenhouse shrubs in the northern states, but grow in the open air at the south.

PRIVY COUNCIL. See **COUNCIL**.

PRIZE, any property captured in virtue of the rights of war. A difference exists in practice between war on land and on the sea in

respect to private property. At sea all the property of every citizen of a belligerent country is liable to capture; but on land it is customary to respect private property. There is, however, no absolute rule on this subject, and in the late civil war both parties passed acts for the confiscation of enemy's property captured on land. Cotton in particular, being the chief resource of the Confederate States, was deemed to be peculiarly a proper subject of capture, and the acts of congress providing therefor were sustained and enforced by the courts.—The general rights of a belligerent are to make captures by his public armed vessels of war, to grant commissions to private persons for the same object, and to establish tribunals of prize for the purpose of examining into all maritime captures, and of judicially deciding upon their validity. By the declaration of war all the citizens of the belligerent countries respectively become enemies, and the citizens of one country may seize any property of the other that they may meet with at sea. Property so seized belongs to the sovereign of the country, and not to the captors, unless it is given to them as an act of grace on the part of their sovereign. For this reason, and also that the government of the country may have the power to limit and control the operations of the war, commissions are usually granted by the government to private persons, authorizing them to make such captures, and after adjudication by a competent tribunal they are entitled to the proceeds of the prizes thus taken. (See **PRIVATEER**.) It is obviously necessary that when a capture has been made there should be some tribunal with authority to pass upon the validity of the capture, and to pronounce a decree of condemnation or acquittal. It is therefore the right and duty of the government of a country, on the declaration of war, to establish tribunals of prize; and it is then responsible to all foreign nations for the correctness of the decisions therein made. So far as the property in question is concerned, the sentence of the prize court is conclusive upon all the world. If the sentence is one of condemnation, the title of the former owner is divested, and all nations are bound to respect the new title acquired under it. But to give the decision of the court this effect, it must appear conclusively that the court had jurisdiction over the property in question. The court must be established in the country of the captor, or in that of his ally in the war, but it is not necessary that the prize should be brought within a port of one of these countries. It is the practice of Great Britain and of the United States to adjudicate upon captures which have been carried into a neutral port.—The next question to be considered is: Who are enemies, and what property is liable to capture? For this purpose not only the native-born citizens of the belligerent are considered as enemies, but all persons who have their domicile in the hostile country; and the citi-

zens of a country which is under the permanent or temporary dominion of the enemies of another country are considered as the citizens of the latter, and all trade with them is illegal, unless the government chooses to recognize the country as neutral, in which case courts of justice are bound by such recognition. It is very doubtful whether a citizen of one country can expatriate himself on the breaking out of war, in order to acquire neutral rights and privileges; but it is certain that if he removes in order to mask his mercantile projects under a neutral flag, such an act is fraudulent and of no avail. But if he has removed during peace, and acquired a domicile in a foreign country, he may engage in trade with a country which is at peace with his adopted country, although at war with that of his nativity. A citizen of one country residing and doing business in another, resumes his native character if, on war breaking out, he puts himself *in itinere* to return to the country of his birth or adoption; but the mere intention without some overt act is not sufficient. A man may have a neutral residence, and yet his property may acquire a hostile character. So, he may be a merchant in more countries than one, and may thus acquire at least a *quasi* domicile besides that of his birth and parentage; and this would be respected by the law, provided there was no indication of fraudulent intention, that is, of giving himself two national characters, between which he could choose from time to time, as suited the exigencies of the moment. The property of a house of trade in an enemy's country is liable to condemnation, whatever be the domicile of the partners who constitute the house. If some of the partners have a neutral residence, their separate property will not be affected by the fact of their being connected with a house of trade in a hostile country. And when a shipment is made by the house to a partner in a neutral country, or by a partner in a hostile country to a house in a neutral country, it depends upon the question to whose account and risk the goods are shipped, whether they are liable to be condemned as prize. Commercial factories in a foreign country, which are free from the control of the government of that country, are considered as belonging to the country by which they are established, and the nationality of persons engaged therein is determined accordingly. But this exception does not apply where the government of the country has the control, although peculiar privileges are granted to the subjects of a particular nation. A foreign minister does not lose his domicile in his own country by residing in the foreign one to which he is accredited; but if he engages in trade there, he is, in respect to such trade, considered as a citizen of the country where it is carried on.—It sometimes occurs that circumstances will not permit property captured at sea to be sent into port. The captor in such a case may destroy it, or allow the master or

owner to ransom it. Such a contract is valid by the laws of nations, but it is prohibited in England by statute. By the ransom bill the vessel is protected from subsequent capture until she reaches her own country, or the country specified in the bill, provided there be no deviation from the course of the voyage. Generally some of the officers and crew are retained as hostages, and if they die, or the vessel is lost by a peril of the sea before her arrival in port, unless it is otherwise stipulated in the bill, the ransom is nevertheless due; for the captors do not insure either the safe arrival of the vessel or the lives of the hostages. If the vessel deviates and is afterward captured and condemned, the better opinion seems to be that the price of the ransom is to be deducted from the proceeds of the prize and given to the first captor, and the residue given to the second. If the captor himself should after the seizure be taken by an enemy's cruiser, together with the ransom bill, the ransom becomes part of the lawful conquest of the enemy, and the debtors of the ransom are consequently discharged from the contract under the ransom bill.—The right which a captor acquires by the seizure is an inchoate right merely, and is subject to be divested before condemnation. If there is a recapture, escape, or voluntary discharge of the property, a court of prize cannot proceed to adjudication. By the Roman law of *jus postliminii*, persons or things taken by the enemy were restored to their former state upon coming again into possession of the nation to which they had belonged. Formerly, as between the belligerents, the title to property captured passed after it had been in the possession of the captors 24 hours; and if after that time it was recaptured by third persons, they became the absolute owners of it. Now, however, the property of the original owners is not divested until condemnation, and the recaptors are merely entitled to salvage, the amount of which is in the United States fixed by statute for most cases, and when not so fixed is determined by the general principles of law. There is some conflict of authority whether the crew of a vessel who recapture it before condemnation are entitled to salvage. It would seem that in the United States they are not, because it is considered to be the duty of the crew to do all that they can to save the vessel until she is condemned. If a treaty of peace makes no particular provisions relative to captured property, it remains in the same condition in which the treaty finds it. In England, as between English subjects, the right of postliminary subsists to the end of the war, and foreign nations are treated with the same liberality which they accord in similar circumstances to England. The property of a subject or an ally engaged in commerce with the enemy is liable to capture; and it makes no difference whether the trade be direct or indirect. The law of nations permits vessels to sail and chase under false colors,

but not to fire a gun or capture under them.—It has become an established principle of the law of nations, that a nation which takes no part in a war shall have the same rights which it has in time of peace, except so far as the exercise of these rights would materially interfere with the permanent rights of the belligerents. Within her own territory, which for this and for other purposes extends a marine league from the shore, a neutral nation is supreme. No belligerent has a right to make a capture in her waters, or to arm or equip his ships of war in her ports, and if either of these things is done the neutral is bound to redress the injury. A ship has no right to station itself in a neutral port and send out boats to make hostile seizures. The neutral nation may allow certain privileges to one of the belligerents, but only such as she is willing to allow to the other. She cannot lend money to one belligerent, but if she is under a previous stipulation, made in time of peace, to furnish a given number of ships or troops to one of the belligerents, the contract may be complied with. If a prize is brought into a neutral port, the neutral government may exercise jurisdiction so far as to restore the property of its own subjects which has been illegally captured. And it has been held in the United States that foreign ships which offend against the laws of that country within its jurisdiction may be seized upon the ocean, and brought back for adjudication. In 1793 the government of the United States established rules of neutrality which it required foreign belligerent powers to observe in their intercourse with this country. Among others was one which provided that if an armed vessel of one nation should depart from our jurisdiction, no armed vessel within the same port and belonging to an adverse belligerent power should depart until 24 hours after the former. It is now a universally admitted principle of the law of nations that a belligerent has a right in time of war to visit and search all vessels on the ocean, in order to determine whether they or their cargoes are hostile or neutral. This right gives also as a necessary incident the right to seize and send in the vessel for adjudication, whenever its real character, or that of its cargo, is justly open to suspicion. The neutral must submit, and if her crew rise and endeavor to recapture the vessel, it is a hostile act, which subjects the vessel and cargo to condemnation. Neutral goods may be carried in a belligerent vessel even if the latter is armed, according to the law in the United States; and a neutral ship is not subject to seizure if she has belligerent goods on board. Attempts have been made at different times to engraft on the law of nations the principle that free ships make free goods, but the law remains unchanged, except as it has been modified by treaties between particular nations. The question whether a country, which during peace confines the trade of its colonies to its own subjects, can during war

open such trade to a neutral, has been much discussed. In England it has been held that it cannot; but this rule has been repudiated by the government of the United States. Neutrals are not permitted to carry goods which are contraband of war, or to enter a blockaded port. (See BLOCKADE, and CONTRABAND.) Breach of blockade forfeits the vessel, and in some cases the cargo; but according to the modern practice, the carrying of contraband goods only forfeits the goods, and the owner of the vessel loses merely his freight and expenses, unless the same person owns both ship and cargo, or some fraud appears in the transaction, in which cases both ship and cargo are forfeited. If an enemy's cargo is captured in a neutral vessel, the vessel has a claim on the captors for freight. But this rule is limited by the reason of it, and if the cargo be contraband, or the voyage be *quasi* contraband, then the neutral vessel loses its freight. The rule that freight is not earned unless the goods are carried to their destination, applies to capture. But if the captor takes the goods where they should have been carried, and even if he does this substantially though not precisely, as by bringing goods to Boston which were destined to New York, freight is due.—All seizures at sea are made at the peril of the captors. If, on being sent in, the vessel and cargo are acquitted, the captors are responsible for all damages and costs, unless the capture was made with probable cause. What is probable cause is a question of some difficulty, and depends very much upon the facts of each particular case. In general, if the papers appeared false or colorable, or were suppressed, mutilated, or spoliated; if the voyage were to or from a blockaded port; or if other circumstances of a like nature occurred, the captors would be justified in sending the vessel in for adjudication. After the vessel is captured, the captors are responsible for any loss which may occur by the negligence, fault, or misconduct of the prize officers and crew; but they are not responsible if a loss occurs from accident, stress of weather, recapture, &c.—While a ship is forfeited by the master's disguising belligerent property on board as neutral, without the authority, assent, or knowledge of the owner, this act does not operate as a breach of neutrality as to the goods on board which are actually neutral and proved to be so by proper documents, and belong to another owner than him who has forfeited the goods. If neutral interests or property are undistinguishably mixed up with belligerent interests or property, they become liable themselves to all the incidents and effects of a belligerent character. A resistance to search when rightfully demanded, an attempt at rescue, and seeking belligerent protection or receiving it, are all breaches of the duty of a neutral. Some question has arisen as to what is a rescue. It is the duty of the captors to put on board persons competent to navigate the vessel into port for

adjudication, and her own master and crew are not bound to do this. If the vessel is given up to them, and they pursue their original course against the wish of the captors, this is not a rescue. But if the neutral crew undertake and promise to navigate the vessel to the desired port for adjudication, and the vessel is given up to them for this purpose, and they violate their promise and take the vessel into their own hands for their own purposes, this is an unlawful rescue. Generally a cargo is considered as liable to condemnation if any act has been committed by the master which subjects the ship to condemnation. But the cargo is not liable to condemnation if it is the property of a person other than the owner of the ship, and its owner was not cognizant of the intended violation. If, however, the owner of the cargo gave the master discretionary power, he is liable for his acts; or if the cargo was loaded after notification of a blockade, the parties having full knowledge of the fact. Resistance to the right of search, the rescue or recapture of the ship by the master and crew, and the fraudulent suppression or spoliation of papers, affect the owner of the cargo as well as the owner of the ship. The principal grounds for condemning a ship as prize, where the question of nationality is in dispute, are: 1, the entire want of the necessary papers; 2, their destruction; 3, their material alteration or falsification; 4, the time when the papers were made out, as whether before or after the war, is often material; 5, next in importance is the conduct of the master and officers; 6, their prevarication or evident falsehood in the preliminary proof; 7, their refusal or inability to give a good account of the ship and cargo; 8, the domicile of the master and officers. The spoliation of papers, by which is meant, not merely their total destruction, but such falsification as makes them useless or worse as evidence, is a circumstance of grave suspicion, though it is open to explanation. Possession by an enemy is presumptive proof, though not conclusive, of hostile character. Ships are presumed to belong to the country under whose flag they sail; and it has been thought that this presumption should be conclusive as against the person using the flag. In joint captures all public ships of war in sight are presumed to assist, and therefore they are entitled to share in the proceeds; and this presumption extends to all the ships of a squadron united by authority for a specific purpose, as for a blockade for example, although not actually in sight; but it does not apply to privateers, because they are not obliged to capture all vessels they meet, as are vessels of war. Revenue cutters, as they are generally employed to protect the revenue, and have no special injunction to capture enemy's vessels, come under the same rule as privateers in this respect. Every ship is expected to have on board the necessary papers to establish her nationality; and these are the papers which the law of her own

country requires as evidence of that character. The same rule applies to cargoes. The sale of a ship or cargo under a decree of admiralty, founded on condemnation as prize, is valid and binding upon all courts and parties, unless it is shown to be vitiated by fraud. But where an attempt is made to establish a revolutionary government, which fails, the adjudications of its prize courts and the sales based upon them will not be recognized, as was held in the case of the late Confederate States.

PRIZE MONEY. The distribution of prize money, or of the proceeds of the sale of ships or goods adjudged by courts of admiralty to be good prize, is carefully regulated by statutes of the United States. The 10th section of the act of June 30, 1864, provides as follows: "The net proceeds of all property condemned as prize shall, when the prize was of superior or of equal force to the vessel or vessels making the capture, be decreed to the captors; and when of inferior force, one half shall be decreed to the United States and the other half to the captors: provided that, in case of privateers and letters of marque, the whole shall be decreed to the captors, unless it shall be otherwise provided in the commissions issued to such vessels. All prize money adjudged to the captors shall be distributed in the following proportions, namely: 1. To the commanding officer of a fleet or squadron, one twentieth part of all prize money awarded to any vessel under his immediate command. 2. To the commanding officer of a division of a fleet or squadron, on duty under the orders of the commander-in-chief of such fleet or squadron, a sum equal to one fiftieth part of any prize money awarded to a vessel of such division for a capture made while under his command, the said fiftieth part to be deducted from the moiety due to the United States, if there be such moiety, otherwise from the amount awarded to the captors: provided that such fiftieth part shall not be in addition to any share which may be due to the commander of the division, and which he may elect to receive as commander of a single ship making or assisting in the capture. 3. To the fleet captain, one hundredth part of all prize money awarded to any vessel or vessels of the fleet or squadron in which he is serving, except in case where the capture is made by the vessel on board of which he is serving at the time of such capture, and in such case he shall share in proportion to his pay with the other officers and men on board such vessel, as is hereinafter provided. 4. To the commander of a single ship, one tenth part of all the prize money awarded to the ship under his command, if such ship at the time of the capture was under the command of the commanding officer of a fleet or squadron, or a division, and three twentieths if his ship was acting independently of such superior officer. 5. After the foregoing deductions, the residue shall be distributed and proportioned among all others

doing duty on board (including the fleet captain), and borne upon the books of the ship, in proportion to their respective rates of pay in the service. No commanding officer of a fleet or squadron shall be entitled to receive any share of prizes captured by any vessel or vessels not under his command, nor of such prizes as may have been captured by any ships or vessels intended to be placed under his command, before they have acted under his orders; nor shall the commanding officer of a fleet or squadron, leaving the station where he had command, have any share in the prizes taken by ships left on such station after he has gone out of the limits of his said command, nor after he has transferred his command to his successor. No officer or other person who shall have been temporarily absent on duty from a vessel on the books of which he continued to be borne, while so absent, shall be deprived, in consequence of such absence, of any prize money to which he would otherwise be entitled. And he shall continue to share in the captures of the vessel to which he is attached until regularly discharged therefrom."

PROBATE, in law, the proof, before the competent authority, that an instrument offered purporting to be the last will and testament of a person deceased is indeed his lawful act. Until the act 20 and 21 Victoria, c. 77 (1857), amended the law relating to probates and letters of administration in England, the custody of the estates of all deceased persons vested there primarily in the ordinaries or bishops of dioceses, subject only to the exceptional rights of the crown or of lords in respect to certain manors. The new act of 1857 abolished the ancient ecclesiastical jurisdiction, and conferred full and exclusive authority over all testamentary causes upon the queen, to be exercised in her name in a court to be called the court of probate. Ecclesiastical courts never existed in the United States; but from the very settlement of the country the office and functions of the English ordinaries have been exercised here by similar officers under various titles, such as surrogate, register of wills, judge of probate, and ordinary, and generally with larger powers than those functionaries possessed. In some states the county courts, and in others the orphans' courts, grant letters of probate. These several judicatures have different powers, some only concerning themselves with the *factum* of a will, leaving its construction, or the operation and effect of its particular provisions, to the courts of law; but others are vested with complete jurisdiction of all matters pertaining to the administration, subject to appeal to some higher court. In England the rule has been that probate was necessary of such instruments only as were testamentary and regarded personal property. If they affected lands alone they needed not to be proved in the spiritual courts. In this country the general rule by statute is that no will is effectual to pass either real or personal estate unless

it has been duly proved and allowed in the probate court; and so long as the probate remains unreversed on appeal, the due execution of the will, the sanity or capacity of the testator, and the attestation of the witnesses, cannot be called in question in the courts of common law. The same rule is in some states observed in respect to wills once admitted to probate, though they were made and executed in other states according to forms not sufficient where they were approved. In some states the probate of wills of lands is *prima facie* evidence, but not conclusive, of the due execution of these instruments; in others the probate becomes conclusive in these respects after the lapse of a certain number of years.—In most of the states the procedure of the court upon probate is fixed by the legislature, and the common law distinction between probate in common form and in solemn form has in great measure disappeared. A will is said to be proved in common form when the executor presents it to the court, and, without summoning any of the parties interested, calls one or more witnesses to prove its execution. The objection to this mode of proof was, at common law, that at any time within 30 years the executor might be called upon by any party in interest to make proof in solemn form. Proof is made in solemn form, or by form of law or *per testes*, when all persons whose interests are to be affected by the will have been duly notified to be present, and have had opportunity to be heard in the premises. This is now the usual mode of proof in the United States, and after the will is approved in this way it is forever binding. The method of proof, however, like many other points of probate practice, is often regulated by particular statute provisions. The testimony which the judge calls for at the hearing relates to the *factum* of the will, as the phrase is. The question being whether the instrument is a will or not, it is of the first importance to inquire into the capacity of the testator, and whether he did in fact execute the alleged will as it purports to have been executed. It is to furnish evidence on both these points that disinterested persons are invited to witness the execution of a will. These attesting witnesses are then most essential parties in a question of probate. Generally all of them must be summoned if they are living within the process of the court; but if from death or absence from the country, or from incompetency arising since the attestation, any witness cannot be produced, the will may be proved by the others and by proof of the handwriting of the party who fails. If all are dead, or out of the court's jurisdiction, the handwriting of all must be proved; and probably in such a case the handwriting of the testator also. The attestation clause is generally framed with a regard to the requirements which the statutes of the state where it is made render essential to the valid execution of a will. If the evidence of the witnesses

shows plainly that these requirements were not followed, the presumption of a valid execution furnished by the recital of them is over-set; but if the subscribing witnesses have lost all recollection of the particulars of the transaction, the formal execution will generally be presumed and the will admitted to probate. Failure of memory on the part of one of the witnesses may often be supplied by the evidence of another or of the rest of them. In affixing his name, an attesting witness is regarded as certifying the capacity of the testator. His subsequent attempt to impeach the instrument by declaring that the testator did not execute the will with an intelligent and disposing mind is justly open to suspicion. Evidence of this character is not to be entirely rejected, though it avails little without the support of other testimony. When 30 years have passed since the death of the testator, a will is said to prove itself; the subscribing witnesses being presumed dead, the bare production of the instrument suffices. The will must however have come from a custody which forbids question of its genuineness, and be in other respects free from suspicion, or the genuineness must in some way be proved.—

Wills alleged to have been lost, destroyed, or mislaid, may be admitted to probate on proof of these facts, and on clear and satisfactory evidence of their contents. For a noted instance of this, see GAINES, MYRA CLARK.

PROBOSCIDIANS, a division of the old order of pachyderms, elevated by Owen into an order by themselves. They include the living elephant and the fossil mammoth and mastodon. They are characterized by the prolongation of the nose into a cylindrical trunk or proboscis, at the extremity of which are the nostrils. The proboscis is very flexible and sensitive, terminating in a finger-like prehensile lobe. Prof. Cope in the summer of 1872 discovered in the eocene of Wyoming several proboscidiens, of the genus *eoobasilus*, large and robust, seeming to connect the elephant with the rhinoceros and dinotherium. (See "American Naturalist" for December, 1872.)

PROBUS, Marcus Aurelius, a Roman emperor, born in Sirmium, Pannonia, about A. D. 230, assassinated there in 282. While he was very young the emperor Valerian raised him to the rank of tribune. He commanded successively the 3d and 10th legions, and served in Africa and Pontus, on the Rhine, the Danube, the Euphrates, and the Nile. Under Aurelian he reconquered Egypt, which had fallen into the hands of Zenobia; and the emperor Tacitus made him commander-in-chief in the eastern provinces. On the death of the emperor in 276 the armies of the East forced him to assume the imperial purple, and the death of his rival Florianus soon left him at the head of the Roman world. He recovered 70 towns from the Germans, destroyed 400,000 of the invaders, and drove the remainder across the Rhine. Penetrating into Germany, he exacted a heavy

tribute of grain, cattle, and horses, and a restitution of the property carried away from the Roman provinces, and made a levy of 16,000 recruits for the Roman army. He built a stone wall from the neighborhood of Neustadt and Ratisbon on the Danube to Wimpfen on the Neckar, and thence to the Rhine, nearly 200 m. He secured the frontier of Rhetia, crushed the power of the Sarmatians, admitted the Goths to an alliance, and took several castles from the Isaurians. He suppressed the rebellion of Saturninus, the commander of the eastern army, and the revolt of Bonosus and Proculus in the West, and returning to Rome celebrated a triumph. To maintain the discipline of his troops, he constantly employed them in active labor, and the hills of Gaul and Pannonia by their toil were enriched with vineyards. This system irritated the soldiers, and finally an unguarded remark, that the establishment of universal peace would render a standing army unnecessary, excited an insurrection in his camp near Sirmium, and Probus fled to a tower; but the troops forced his retreat, and put him to death. He was succeeded by Carus.

PROCESS, in law, a term which, in a large sense, signifies the whole proceedings in any action, civil or criminal, real or personal, from the beginning to the end. In a narrower and more technical sense, the term is applied to different stages of the procedure; as is seen in the terms original process, which includes those precepts or writs by which one is called into court; final process, or the forms of procedure by which judgment is carried into execution; and mesne process, which covers the proceedings between the other two, and embraces all proceedings properly so called, all writs for compelling the attendance of jurors or witnesses, and for other collateral purposes. Mesne and final process are sometimes collectively described by the term judicial process, because proceedings in these stages of an action were authorized immediately by the courts, and issued under the hands and seals of their presiding judges. Original process, on the other hand, was so called because it was founded on the original writ, which, issuing out of chancery, and bearing the *teste* of the sovereign, conferred jurisdiction on the court to which it was addressed, and founded its authority over the matter in controversy. In the strict technical sense, process is the means employed for bringing the defendant into court to answer to the action. The first step therefore in the ancient procedure was to give the defendant notice of the issue and pendency of the original writ. This notice was given ordinarily by summons, which was a warning to the party to appear at the return of the writ, and was served upon him by the sheriff or some of his messengers. If the defendant disregarded this monition, the next step was a writ of attachment, bidding the sheriff to take certain of his goods to be forfeited if he failed to appear, or to take the pledges of certain sureties of the

defendant, who should be amerced in case of his non-appearance. If the sheriff made return that the defendant had no goods whereby he could be attached, or if after attachment he failed to appear, the court issued a writ of *capias* commanding the sheriff to take the defendant's body. This writ and all others subsequent to it were called judicial, because, as we have already seen, they proceeded immediately from the court, and not from chancery. The proceedings before *capias* became in time merely formal, and it was usual to sue this out in the first instance upon a supposed return of the sheriff. The old and somewhat complicated and inconvenient process for the commencement of suits is now abolished in England, and a simple summons supplies the place. —The proceedings in civil suits vary in the different states of the Union, and frequently in different courts of the same state. In some states the old common law procedure, modified more or less by statute, is in use, while in others a code of civil procedure similar to that of New York has been adopted. (See CODE, vol. v., p. 10.) The necessary proceedings in the regular course of a civil suit in the New York supreme court, to which a defence is interposed, are as follows: 1. The service, by delivering a copy to the defendant personally, of a summons, which may or may not be accompanied with the complaint, and which requires answer to be made to the complaint within 20 days, and contains a notice, according to the nature of the suit, that in default of answer judgment will be taken for a specified sum, or that application will be made to the court for the relief demanded in the complaint. *a.* The service within 20 days on plaintiff's attorney by defendant's attorney of a notice of appearance in the suit, with a demand for a copy of the complaint. *b.* The service within 20 days by plaintiff's attorney on defendant's attorney of a copy of the complaint, setting forth the grounds of the suit and demanding the appropriate judgment. 2. The service within 20 days on plaintiff's attorney by defendant's attorney of a copy of the answer, containing a denial of the allegations of the complaint, or new matter, such as payment, constituting a defence to the plaintiff's claim. *c.* If the answer, as is sometimes the case, contains an affirmative claim against the plaintiff, the service within 20 days by plaintiff's attorney on defendant's attorney of a reply interposing a denial or defence to such claim. 3. The service by the attorney of either party desiring to bring on the case for trial, on the attorney for the other party, of a notice of trial at least 14 days before the beginning of the term of court for which the notice is given. 4. The filing with the clerk of the court, at least eight days before the beginning of the term, by the attorney giving notice of trial, of a note of issue containing certain particulars to enable the clerk to place the case on the calendar of the court.

5. The trial, with or without a jury according to the nature of the suit, when the case is reached in its order on the calendar. 6. The filing in the clerk's office by the attorney for the prevailing party of the judgment roll, consisting of a certified copy of the clerk's minutes taken on the trial and a statement of the judgment drawn up by the attorney, together with the summons, complaint, answer, &c. 7. The issuing by the attorney for the prevailing party of an execution to the sheriff, who returns the same within 60 days, satisfied or unsatisfied as the case may be. When the complaint is served with the summons, *a* and *b* are not required. There are numerous collateral and subsidiary proceedings which may, and some of which commonly do occur in a suit. The time for the service of papers may be extended by the court. When the losing party desires to appeal from the judgment, he must upon notice to the other party have a "case" settled by the judge, which shall present the question to be considered by the higher court. A notice of appeal must be served on the prevailing party by the appellant within 30 days after he shall have received written notice of the judgment, and he must also serve on the prevailing party printed copies of the case. Either party may serve on the other a notice of argument and file a note of issue, when the case is placed on the calendar of the appellate court and argument had and judgment entered in due course. The appeal in the first instance is to the general term of three judges, and from their decision another appeal may be taken in similar manner to the court of appeals. When the appellant desires all proceedings to enforce the judgment to be stayed pending the appeal, he must furnish an undertaking with sureties to the effect that he will pay the judgment with costs and damages if it be affirmed.—In the criminal law process applies in an extensive sense to all those instruments which are used by competent authority for the purpose of bringing a party into court, or of executing the judgment of the law upon him.

PROCLUS, a Greek philosopher of the Neo-Platonic school, born in Constantinople in A. D. 412, died in Athens in 485. In his childhood he lived at Xanthus in Lycia, afterward for several years in Alexandria, studying under the most eminent teachers, and before he was 20 years old removed to Athens. On the death of Syrianus he succeeded him in the school at Athens, and hence is sometimes called Diadochus (the successor). He adopted the ascetic system which became common in the later Neo-Platonic school, abstained almost entirely from animal food, refused to marry, spent his money freely in acts of benevolence, and observed numerous fasts and vigils. He worshipped the sun and moon, the spirits of heroes and philosophers, and even the spirits of the whole human race, and celebrated all important religious festivals, no matter of

what nation. In addition to his religious exercises, he delivered five lectures a day. He was distinguished as a mathematician and grammarian. His extant works consist chiefly of commentaries, principally on Plato. One of his original works is entitled "Twenty-two Arguments against the Christians," in which he endeavored to maintain the eternity of the universe. As a writer he is usually regarded as one of the clearest of his school, but as a philosopher his reputation has never stood high. There is no complete edition of his extant productions; the best is by Cousin (6 vols. 8vo, Paris, 1820-'27). Translations of several of his works have been made into English by Thomas Taylor.

PROCONSUL, a Roman magistrate who acted for the consul in the government of a province, and was almost always one who had previously been consul. The first proconsul was Q. Publius Philo, who in 327 B. C. was at the head of the army in the second Samnite war when his consular year closed, and was then continued in the function beyond his time because his recall would have destroyed the advantages already gained.

PROCOPIUS, a Byzantine historian, born in Cæsarea, Palestine, about A. D. 500, died about 565. He early removed to Constantinople, and became distinguished as an advocate. In 527 he was chosen secretary by Belisarius, and accompanied him in his wars against the Persians, the Vandals in Africa, and the Goths in Italy, where he had charge of the commissariat department, and was at the head of the fleet. Returning to Constantinople about 542, he received from the emperor Justinian the title of *illustris* and the position of senator, and in 562 was made prefect of the city. The most important work of Procopius is his elegant and interesting "History" of his own times in eight books. It has been translated into English by Sir Henry Holcroft (fol., London, 1653). Another work, entitled *Anecdota*, probably by Procopius, though the authorship is questioned, consists of a collection of anecdotes portraying, and here and there perhaps spitefully caricaturing, the morals of the Byzantine court. An English translation of it was published anonymously under the title of "The Secret History of the Court of the Emperor Justinian" (London, 1674). The best edition of Procopius's collected works is by Dindorf (3 vols., Bonn, 1833-'38).—See *Procopius von Cæsarea*, by Dahn (Berlin, 1865).

PROCOPIUS. I. Andrew, called the Great, a leader of the Hussites, born toward the close of the 14th century, died at Böhmisch-Brod, Bohemia, May 30, 1434. He was adopted and educated by his uncle, a nobleman in Prague, who travelled with him through France, Spain, Italy, and the Holy Land. On his return he received clerical orders, and at the outbreak of the Hussite war he joined the sectarians, rose to the rank of a captain, and relieved the besieged town of Lundenburg in Moravia. In

1423 he gained a victory at Kremsier, and in 1424, on the death of Ziska, the Taborites elected him their leader. In conjunction with other Hussite captains he devastated Austria, Franconia, Saxony, and Silesia. Procopius the Small joined him in 1427, and the concentration against them of German forces from all sides led to a general confederation of the various Hussite parties under his banner. With this considerable army he defeated the Germans, ravaged the whole of Silesia and Moravia, and penetrated as far as Presburg in Hungary. In 1429 he turned to the north and pillaged and destroyed everything before him in order to weaken the power of the Germans. In 1430 he led an army of about 75,000 men into Franconia and Lower Bavaria, burning about 100 towns and castles and more than 1,000 villages on his way. Cardinal Julian finally succeeded in gathering another army of German crusaders. Frederick of Brandenburg took the command, and occupied Bohemia; but when Procopius appeared with his forces, the Germans at once took to flight (Aug. 14, 1431). Procopius continued his devastations in Silesia, Hungary, and Saxony, but finally sold a truce of two years to Silesia and Saxony for large sums of money. In 1433 he attended the council of Basel, where he defended with much spirit the creed of his party, attacking especially the order of the monks, which he called an invention of the devil. Tired of the long disputations, he finally refused further to attend the council, and returned to Bohemia. Ten theologians and several princely legates were thereupon sent to Prague to continue the conference, and they succeeded in bringing about a compromise with the Calixtines. Procopius, not satisfied with the new articles of faith, besieged the city of Pilsen, and when the Calixtines had formally accepted the *Compactata* he turned his arms against them. The decisive battle was fought in the neighborhood of Böhmisch-Brod, E. of Prague, May 30, 1434, where Procopius was defeated and killed. (See HUSSITES.) **II. The Small**, the leader of the Hussite party of Orphanites, joined Procopius the Great in 1427, shared with him the conduct of the war, and died at his side.

PROCRUSTES (Gr. Προκρούστης, the stretcher), the surname of Polypemon or Damastes, a legendary robber of Attica, who had an iron bed upon which he placed all the travellers who fell into his hands. If they were longer than the bed, he cut enough from their limbs to make them fit; if they were shorter, he stretched them. He was slain by Theseus on Mt. Cephissus.

PROCTER. I. Bryan Waller, an English poet, better known by his anagrammatic pseudonyme of Barry Cornwall, born in London about 1790, died there, Oct. 5, 1874. He was educated at Harrow, passed some time in the office of a solicitor in Wiltshire, removed to London, and in 1831 was called to the bar from Gray's Inn.

For several years he was a commissioner in lunacy, resigning in 1861. His first publication was a volume entitled "Dramatic Scenes and other Poems" (1819), which was followed by "Marcian Colonna, an Italian Tale; with three Dramatic Scenes, and other Poems" (1820); "A Sicilian Story, with Diego de Montilla and other Poems" (1820); "Mirandola, a Tragedy" (1821); "The Flood of Thessaly and other Poems;" "Poetical Works" (3 vols., 1822); "Effigies Poeticæ" (1824); "English Songs and other Small Poems" (1832); "Life of Edmund Kean" (1835); "Essays and Tales in Prose" (1851); and "Charles Lamb, a Memoir" (1866). His "Mirandola" was produced with success at Covent Garden in 1821. He is best known by his songs, some of which are singularly well adapted to music, and are equally refined in sentiment and diction. All his publications appeared under his assumed name of Barry Cornwall. **II. Adelaide Anne**, a poetess, daughter of the preceding, born in London, Oct. 30, 1825, died there, Feb. 2, 1864. She published "Legends and Lyrics, a Book of Verse" (1858), and "A Second Volume of Legends and Lyrics" (1860). Both series with new poems appeared in one volume in 1865, with an introduction by Charles Dickens.

PROCTOR (Lat. *procurator*, agent), in a general sense, one who is commissioned to manage the business of another. In a particular sense, a proctor is one who is commissioned to transact the business of his principal in the ecclesiastical or admiralty courts. He discharges functions similar to those of attorneys and solicitors in other courts. In England, the proctor can be admitted to practice only after a clerkship of seven years with a senior proctor of at least five years' standing, and he must produce a certificate of considerable proficiency in classical education. Before the abolition of the probate and matrimonial courts of doctors' commons, the proctors were the only persons allowed to practise in them. (See **DOCTORS' COMMONS**.) Proctors are known in the United States only as officers of the courts of admiralty, whose duties, authority, and responsibilities correspond to those of attorneys at law.—The name proctor is also given in England, and in some American colleges, to university officers whose duty is to guard morals and order.

PROCTOR, Richard Anthony, an English astronomer, born in Chelsea, March 23, 1837. He was educated at home until his 11th year, and then entered an academy in Milton-on-Thames, where he remained three years and became head boy of the institution. After the death of his father in 1850 the family became embarrassed through chancery delays in a friendly suit, and in 1854 Richard accepted a clerkship in a London bank, devoting all his spare time to the study of mathematics. In 1855, the situation of the family having been improved, he entered King's college, London, and in 1856 St. John's college, Cambridge. He took his

degree in 1860, and married in the same year. For the next three years his studies were mostly historical and literary. In 1863 he wrote an essay on "Double Stars," which appeared in the "Cornhill Magazine." In 1865 he published a monograph on "Saturn," and early in 1866 his "Gnomonic Star Atlas" and "Handbook of the Stars." These works were of a scientific, but not popular nature. In 1866, by the failure of a bank in London, he lost the whole of his fortune, and his scientific work was considerably hampered by duties arising from this circumstance. In 1869 he made some suggestions to the astronomer royal, Sir George Airy, as to the best method of observing the approaching transit of Venus; and at a meeting of the principal astronomers of England at the Greenwich observatory in 1873 his views were unanimously approved. But his chief scientific work since 1867 has consisted in the investigation of the evidence available for determining the structure of the stellar and nebular universe. (See **STAR**.) In 1870 Mr. Proctor published a work entitled "Other Worlds than Ours," which had an extraordinary success and attracted the general attention of the scientific world. From that time he has been perhaps the most fertile and popular writer upon astronomical subjects of the present day. In 1873 he visited the United States and delivered lectures, and again in 1875. His published books besides those above mentioned are: "Constellation Seasons" and "Sun Views of the Earth" (London, 1867); "Half Hours with the Telescope" (1868); "Half Hours with the Stars" (1869); "The Sun," a large "Star Atlas," "Elementary Astronomy," and "Light Science for Leisure Hours" (1870); "Essays on Astronomy" and "Orbs Around Us" (1871); "Chart of 324,000 Stars," "School Atlas of Astronomy," and "Elementary Physical Geography" (1872); "Light Science," &c., second series, "The Moon," and "Border Land of Science" (1873); and "The Universe and Coming Transits," "Transits of Venus, Past, Present, and Future," and "The Expanse of Heaven" (1874).

PROFET. See **OYER**.

PROHIBITION, a writ issued by a superior court to restrain the action of an inferior tribunal which is assuming to act in some matter not within its cognizance, or in disregard of the rules which govern the exercise of its jurisdiction. It is an extraordinary remedy, to which resort seldom becomes necessary.

PROJECTILES. See **GUNNERY**.

PROKESCH-OSTEN, Anton von, a German author, born in Gratz, Dec. 10, 1795, died Oct. 26, 1876. He served in the army, taught mathematics, and was secretary to Prince Schwarzenberg, whose *Denkwürdigkeiten* he edited in 1822. For his subsequent services in the East he was ennobled with the name of Von Osten, and he was afterward made privy councillor and general. He was ambassador at Athens 1834-'49, Berlin 1849-'52, Frankfort 1853-'5, and

Constantinople 1855-'67, and nuncio at Constantinople 1867-'72. His celebrated collection of coins was bought by the Prussian government in 1875 for the museum of Berlin, for \$150,000. Among his works are: *Erinnerungen aus Aegypten und Kleinasien* (3 vols., Vienna, 1829-'31); *Denkwürdigkeiten und Erinnerungen aus dem Orient*, edited by E. Münch from Prokesch's correspondence with Schneller (3 vols., Stuttgart, 1836-'7); *Kleine Schriften* (7 vols., 1842-'4); and *Geschichte des Abfalls der Griechen vom türkischen Reich* (6 vols., Vienna, 1867-'8).

PROME, a town of British Burmah, in Pegu, on the E. bank of the Irrawaddy, 166 m. N. N. W. of Rangoon; pop. about 30,000. It is surrounded by a brick wall $1\frac{1}{2}$ m. in circumference, has several paper manufactories, and is a place of considerable commercial importance. A railway is projected to Rangoon. In the suburbs are extensive rice grounds. Prome was taken by the British in 1825, and again in the second war with Burmah in 1852. It was nearly destroyed by fire in 1856, and in the same year suffered seriously from an inundation of the Irrawaddy.

PROMETHEUS, in Grecian mythology, the son of Japetus and Clymene, and brother of Atlas, Menœtes, and Epimetheus. According to Hesiod, gods and men were in a dispute at Mecone in regard to what portion of the animal should be offered in sacrifice. Prometheus, as the tutelary representative of man, divided a bull into two parts, one consisting of the flesh and intestines wrapped in the skin, and the other of the bones covered up by the white fat. Jupiter, having been asked which of the two he would choose, decided for the latter; and as the choice could not be revoked, those parts alone were thereafter offered on his altar. Indignant at the deception, he withheld fire from mortals, but Prometheus stole fire from heaven in the hollow of a tube. Jupiter now sent Pandora to earth with her box of evils, and fastened Prometheus to a pillar, where he remained for many generations, an eagle every day feeding upon his liver, which every night grew again. At length Hercules was permitted to kill the eagle and free the prisoner. The most celebrated drama founded upon this myth is the trilogy of Æschylus, of which the "Prometheus Bound" and a few fragments of the "Prometheus Loosed" are extant. In Æschylus, Prometheus appears not only as the protector of the human race against the superior might of the gods, but as its teacher and benefactor. Through his assistance, Jupiter overcomes the Titans; but when Prometheus frustrates the design of destroying mankind, he is chained to a rock in Scythia. There he is visited by the Oceanids and by Io, to whom he foretells her long wanderings. He is in possession of knowledge which it is essential to the safety of Jupiter to gain; but he bids defiance to his persecutor, and refuses to make known the secret. He is hurled into Tartarus, and

afterward reappears chained to Mount Caucasus, to undergo fresh torments. From this condition he can only be freed when some other god shall voluntarily descend into Tartarus for him, which finally happened when Chiron, wounded by Hercules, sought permission to go into Hades. Another account says that Jupiter himself delivered Prometheus when the latter agreed to reveal the prophecy, according to which, if he were married to Thetis, she would give birth to a son greater than himself.

PROMISSORY NOTE, a promise in writing to pay money. When the promise is to pay it to the payee or his order, or to the bearer, the note is negotiable, and, as an exceedingly useful and important instrument of business, it is governed by a system of law which is quite peculiar. When not payable to order, or not negotiable, the rules of law applicable to it vary but little from those which are in force generally in relation to written contracts. (See EXCHANGE, BILL OF, and NEGOTIABLE PAPER.)

PRONG HORN. See ANTELOPE.

PROPAGANDA, or *Congregatio de Propaganda Fide* (congregation for propagating the faith), a board of 25 cardinals founded at Rome in 1622 by Gregory XV. for the support and direction of foreign missions. It has a secretary, who is generally a bishop or archbishop, and priests, advisers, and under secretaries, who hold a consultation weekly. The cardinal prefect of the propaganda is the pope's representative in all matters concerning the affairs of foreign missions, including the final appointment of all bishops in missionary countries. Pope Urban VIII. in 1627 added to the congregation a college for the education of missionary priests, where young men from every country in the world, with the exception of strictly Catholic countries, were educated, and ordained for the missionary work among their fellow countrymen. A celebrated polyglot printing establishment was attached to the propaganda, and besides a full corps of professors, it possessed a museum of antiquities and curiosities, a handsome church, and a large library. This college was suppressed in 1873, and its property was sold by auction.

PROPAGATION OF THE FAITH, *Society for the (la société pour la propagation de la foi)*, a Roman Catholic society in aid of foreign missions founded at Lyons in 1829. Its plan is to raise, through committees and sub-committees, one cent a week from each subscriber, the money being forwarded to the central committee at Lyons, by whom the funds are apportioned to bishops of the various missionary countries throughout the world. The society spread rapidly over the whole of Europe, and has now paying members in almost every country in the world. It is sometimes confused with the Roman propaganda, with which it has nothing in common except a similar object. The central committee at Lyons publishes six times a year the *Annales de la pro-*

pagation de la foi, to inform the subscribers of the use made of the funds and of the progress of the missionary work.

PROPERTIUS, *Sextus Aurelius*, a Roman poet, born in Umbria about 50 B. C. He was rich until an agrarian division, in 36 B. C., reduced his fortune. He wrote four books of elegies, principally addressed to his mistress. The text of Propertius as we have it is exceedingly corrupt. One of the best editions is that of Hertzberg (2 vols. 8vo, Halle, 1843-'5). His elegies have been translated into English verse by Charles Robert Moore (Oxford, 1870).

PROPHECY (Gr. *προφητεία*, from *προφάναι*, to foretell), the prediction of future events. The belief that certain men or classes of men had the faculty of prediction can be traced to the remotest antiquity; and the priesthood in particular were regarded as being endowed with it. But the term prophecy, in this sense, is generally restricted to the Old Testament theology. The word prophet in the languages of Christian nations is derived from the Greek *προφήτης*, by which the Septuagint renders the Hebrew *nabi*. But the term of the Septuagint does not fully correspond to the primary meaning of the Hebrew word, which denotes a man speaking by divine inspiration; though sometimes the word is used in a bad sense of men who only pretend to inspiration, or are inspired of an evil spirit.—The prophets of the Old Testament appear as the privileged organs of communication between God and his people. Frequently, though for the most part indefinitely, they pointed to a glorious completion of the theocracy through a great descendant of David, the Messiah. They also acted as the interpreters of the law, and were guardians of the rights of the oppressed. Their mission, as a body of extraordinary teachers, became especially important in times when the ordinary guardians of the law, the priests, sided with the apostates and idolaters. The germ of the prophetic office is found in the Mosaic economy, but the order was formally developed by Samuel, when the moral decline of the nation had made it necessary. In the age of the judges, prophecy, though existing only in scattered instances, exerted a powerful influence. But the conspicuous prophetic agency begins with Samuel, who founded schools of the prophets at Gibeah, Ramah, Bethel, Jericho, and Gilgal. Instruction was given in the interpretation of the divine law, and in music and sacred poetry. Samuel, Elijah, and Elisha are mentioned as principals of such institutions. The pupils are frequently called the "sons of the prophets." The prophets were mostly taken from these schools, yet not always; for Amos relates of himself that he had been trained in no school, but was a herdsman when the Lord took him to prophesy unto the people of Israel. Sometimes, but rarely, it occurred that women came forward as prophetesses. The golden era of the prophets extends from the time of Samuel to the Babylonish captivity, and hardly

any important event happened in which they did not appear as performing the leading part. After the time of Samuel they often held weekly and monthly meetings for teaching, that work being tacitly transferred from the priests to the prophets. About 100 years after the return from the Babylonish captivity the prophetic profession ceased, and Haggai, Zechariah, and Malachi are uniformly mentioned by Jewish tradition as the last of the prophets.—The manner of life of the prophets was conspicuous for strictness, austerity, and asceticism. Some of them appear to have been in possession of considerable physical and medical knowledge, and to have occasionally made use of it. Later they often wrote down their prophecies, and many others compiled historical works. Thus Gad, Nathan, and perhaps Samuel, wrote the history of David; Nathan also the history of Solomon; Shemaiah and Iddo the history of Rehoboam; Jehu the history of Jehoshaphat; and Isaiah the history of Uzziah and Hezekiah.—The New Testament mentions the power of prophecy as one of the gifts of the Holy Spirit. We read of one prophet, Agabus, who predicted the famine under Claudius and the imprisonment of Paul; but generally a foreknowledge and foretelling of futurity is not mentioned as characteristic of those men who, as Barnabas, Judas, and Silas, are called prophets in the Acts and the Pauline epistles. The object of the Christian "prophecy" was, according to 1 Cor. xiv. 3, "edification and exhortation and comfort." Among the books of the canon of the New Testament only one, the Revelation, bears a prophetic character.—The mode in which the divine will was revealed to the prophets has been the subject of much discussion. The Bible declares that sometimes God spoke to them in an audible voice, sometimes in dreams, sometimes by giving them an ecstatic elevation in which they saw truths ordinarily unseen, and sometimes by visions. Many writers, especially since the middle of the last century, have endeavored to show that the Scriptures do not assert a direct and miraculous supernatural interference, and that the prophetic inspiration can be explained by a high degree of religious enthusiasm and ecstasy. Among these writers are Eichhorn, *Die Hebräischen Propheten* (3 vols., Göttingen, 1816-'20); Knobel, *Der Prophetismus der Hebräer* (Breslau, 1837); Ewald, *Die Propheten des Alten Bundes* (Stuttgart, 1840); and Dr. Williams in the Oxford "Essays and Reviews." With regard to the predictions occurring in the books of the prophets, this class of writers either ascribe them (as Bunsen did) to a kind of spiritual clairvoyance, or they maintain (with Dr. Williams) that few if any passages can be claimed as strictly prophetic, the prophetic utterance containing only certain "deep truths and great ideas." The great majority of Christian theologians maintain that this view is opposed by the plain intent of the

Old Testament, by the counter testimony of Christ and the apostles in the New, and also by the concessions of unbelieving interpreters, such as Strauss, who say that the Scriptural writers undoubtedly claim prophetic inspiration, but that the claim is absurd. Among the works written from this standpoint are Prof. Fairbairn's treatise on "Prophecy, its Nature and Functions" (8vo, Edinburgh, 1856), and especially Tholuck, *Die Propheten und ihre Weissagungen* (Gotha, 1860), who has reviewed the whole subject in a philosophical manner, and concludes that the prophecies cannot be interpreted "as the utterance of subjective religious aspirations," and that "the very course of history has impressed upon these declarations the stamp and confirmation of an objective and supernatural inspiration." The reader may also consult various commentaries on the books of the prophets, and that class of works which limit themselves to an interpretation of the "Messianic prophecies" throughout the entire Old Testament, among which Hengstenberg's *Christologie* (3 vols. 8vo, Berlin, 1829-'35; English translation, 1836-'9, and in Clark's "Foreign and Theological Library," 1854) is the best known.—Besides the works already named, see Köster, *Die Propheten des Alten und Neuen Testaments* (Leipsic, 1838); Davison, "Discourses on Prophecy" (Oxford, 1839); Stuart, "Hints on the Interpretation of Prophecy" (Andover, 1844); Maurice, "Prophets and Kings of the Old Testament" (1853); Pusey, "The Minor Prophets" (Oxford, 1861); R. Payne Smith, "Messianic Interpretation of the Prophecies of Isaiah" (1862); and Stanley, "Lectures on the Jewish Church" (1863).

PROPHETS, Books of the, a division of the Old Testament. The rabbis divided the books of the Hebrew canon into three classes: 1. *Torah*, law; 2. *Nebiim*, prophets; 3. *Kethubim*, writings, hagiographa. The second class was subdivided by them into "former" and "latter" prophets. The former comprised the books of Joshua, Judges, Samuel, and Kings. Among the latter they again distinguished between the three "great" (Isaiah, Jeremiah, and Ezekiel) and the twelve "minor" prophets (Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi). In the arrangement of modern Biblical criticism, Joshua, Samuel, and Kings are not counted among the books of the prophets, who are divided into the four great (Isaiah, Jeremiah, Ezekiel, and Daniel) and the twelve minor prophets.—See also the articles on the several prophets.

PROPONTIS. See MARMORA, SEA OF.

PROSERPINE, or *Persephone*, in Greek and Roman mythology, the queen of the infernal world. She was the daughter of Jupiter and Ceres, and was beloved by Pluto, who forcibly carried her off to Hades. There she was found by Ceres, who induced Pluto to consent that her daughter should pass six months of

every year in the upper world with her; and hence Proserpine became a symbol of vegetation. The Eleusinian mysteries belonged to her in common with her mother, and she had temples at Corinth, Megara, and Sparta, and at Locri in the south of Italy.

PROSPER (AQUITANUS), Saint, a church father of the 5th century, born near Bordeaux about 403, died about 464. He was distinguished as a chronologist, poet, and theologian, and is chiefly known from the prominent part taken by him in opposing Cassian and the Semi-Pelagians of Marseilles. Among the many works written by him against these and in defence of St. Augustine is the *Carmen de Ingratis*, considered to be one of the best Latin poems written by a Christian author. It is asserted, but on doubtful authority, that he became in 440 secretary or *notarius* to Leo the Great, and that he wrote the letters on Eutychianism attributed to that pope. He drew up about 444 a paschal cycle of 84 years, which has perished, and a continuation of the chronicle of St. Jerome, from A. D. 379 to 455, under the title of *Chronicon Consulare*. Photius ascribes the final overthrow of Pelagianism to his unwearied labors. His feast is celebrated on June 25. St. Prosper appears to have lived and died a layman, though some writers have made him bishop of Riez (Rhegium) in Provence. There are several complete editions of his works, the best being those of Maugeant, with a history of his life, translated from Tillemont (fol., Paris, 1711), and Foggini (fol., Rome, 1752), reprinted in vol. li. of Migne's *Patrologie latine*.

PROSTATE GLAND (Gr. *προστατήν*, to stand before), a solid, chestnut-shaped glandular body, rather more than one inch in diameter, situated in the male between the neck of the bladder and the membranous portion of the urethra; so called because it stands in front of the neck of the bladder. The texture of the prostate gland consists of a large number of racemose or compound glandules, surrounded by and imbedded in an abundant fibro-muscular tissue, and opening by several separate orifices into the first or prostatic portion of the urethra, which canal it embraces at this point for about an inch. The prostate is liable to become enlarged in advanced life, when it sometimes creates an obstacle to the evacuation of the urine.

PROTAGORAS, a Greek philosopher, born in Abdera probably about 480 B. C., died about 411. The common story in regard to his origin was that he was a porter, and by the skillful manner in which he carried his load attracted the attention of Democritus, who undertook to educate him. He was the first who assumed the title of sophist, as denoting one who instructed others in the art of becoming wise, and in the arts of eloquence and politics, and was also the first who received pay for his lessons. According to Plato, he received more money during the 40 years in which he

taught than Phidias and 10 other sculptors. None of his works are extant. For saying, in his treatise "On the Gods," "Respecting the gods, I am unable to know whether they exist or do not exist," Protagoras was banished from Athens, and his books were burned.

PROTAIS, Paul Alexandre. See supplement.

PROTECTOR, in English history, a title several times conferred by parliament upon the chief officer of the kingdom during the king's minority, in place of that of regent. The most celebrated protectors were John, duke of Bedford, and Humphrey, duke of Gloucester, in the minority of Henry VI.; Richard, duke of Gloucester, whose protectorate ended in his becoming king as Richard III. after the death of Edward V.; and Edward Seymour, duke of Somerset, in the minority of his nephew Edward VI. Oliver Cromwell, as well as his son Richard, bore the title of lord protector.

PROTEIDS. See PROTEINE.

PROTEINE (Gr. *πρωτος*, first), a name given by Mulder to a product obtained by the action of potash on albuminoids, such as fibrine, albumen, and caseine, of which he considers it the base, the other factor being varying quantities of sulphimide, $(\text{NH}_2)_2\text{S}$, and phosphimide, NH_2P . It has, however, never been procured free from sulphur, and Liebig regarded Mulder's theory as not established, considering it only an albuminous substance somewhat modified. But the bodies of which Mulder considered it the base are commonly called proteine bodies, or proteids, and are divided, according to Hoppe-Seyler, into seven classes, viz.: 1. Albumens (soluble in water): *a*, serum albumen; *b*, egg albumen. 2. Globulines (insoluble in water, but soluble in dilute acids and alkalies, and very dilute solutions of chloride of sodium and other neutral salts): *a*, myosine; *b*, globuline; *c*, fibrinogen; *d*, vitelline. 3. Derived albumen (insoluble in water and solutions of chloride of sodium, but soluble in dilute acids and alkalies): *a*, acid albumen; *b*, alkali albumen or caseine. 4. Fibrine (insoluble in water, sparingly soluble in dilute acids and alkalies and in neutral saline solutions). (See FIBRINE.) 5. Coagulated proteid, formed by heating neutral solutions of proteids, or by the action of alcohol. 6. Amyloid substance, or lardaceine, a substance deposited in the liver and other organs in certain diseases. 7. Peptones, bodies formed from albuminous substances by the action of the gastric juice; they are found only in the stomach and small intestines, disappearing as soon as they enter the lacteal vessels.

PROTESILAUS, a legendary Thessalian prince, the first Greek slain in the Trojan war. It is said in the Iliad that he was the first who leaped from the ships upon the Trojan shore, and according to the ancient tradition recounted in Lucian he was killed by Hector. The great affection toward Protesilaus of his wife Laodamia is celebrated by the poets. After his death she prayed to be permitted to converse with him only for the space of three

hours; the prayer being granted, Mercury conducted Protesilaus to the upper world, and when he died a second time his wife died with him.

PROTEST (Lat. *protestari*, to testify or declare against), a term used in many ways and for many purposes. One who is called upon to pay an import duty, a tax, a subscription, or the like, which he thinks he ought not to be required to pay, but is unwilling to encounter the delay and expense of a lawsuit at that time, pays the sum demanded under protest; that is, he accompanies the payment by a written and attested declaration of what he deems the illegality of the demand, and of his rights of defence and denial. This protest preserves all those rights; and in any subsequent suit or other effort to get the money back, the protest will prevent him from being impeded by his payment.—In legislation, the members of a deliberative body who dissent from the views of a majority, and have no power to prevent those views from going into effect, sometimes ask leave to put on the record of the body a declaration of their views, drawn up and signed by them. This is called their protest against the measure; and leave to record it is usually given, if it is decent and temperate in its terms, and does not state what the majority regard as wilfully false or impertinent.—If a vessel is wrecked, or meets with other injury from any peril of the sea, it is an ancient and nearly universal custom for the master, on his arrival at port after the injury, to appear before a competent magistrate, and enter his protest against the accident or peril. In this protest he details the circumstances with sufficient fulness to sustain his declaration that the injury occurred, not through the fault of the vessel, but by reason of the peril stated. In the absence or disability of the master, the protest is made by the officers, or even by the seamen; and when it is made by the master, he is usually accompanied by one or more of the officers, and by some of the seamen.—A very important use of protest is made in the case of dishonored bills of exchange. (See EXCHANGE, BILL OF.) It is a universal law that a foreign bill of exchange, if not accepted, or if not paid at maturity, must be protested in order to hold all the parties to it. In this sense, the states of the Union are foreign to each other. Inland (or domestic) bills and promissory notes are often protested in the same way; but this usage, so far as it exists, has grown up from the convenience of it, and not from any requirement of the law merchant. The protest should be made by a notary public; and full faith is given in all countries to all the official acts verified by his seal, which acts are required by law merchant. He cannot properly delegate this power to any clerk or substitute. An acceptance or payment *supra* protest takes place when, a bill having been protested, a third person intervenes, and accepts or pays the bill for the honor of the party whose duty it was to accept or pay it;

and this gives him a right to indemnity from the person for whom he accepts or pays. An acceptance or payment *supra* protest is sometimes called an acceptance or payment for honor. Generally, where one accepts or pays for honor without designating for whose honor he acts, it will be deemed that he acts for all who were bound by the paper, and he acquires his right of indemnity against all whom he thus protects. But he may designate, if he chooses, the party for whose honor he acts, and then he protects only that party, and has no claim or rights against any other.

PROTESTANT, a collective name for a large body of Christian denominations, embracing in general all except the Roman Catholic and eastern churches. The name originated in 1529 in Germany, at the diet of Spire. The majority of the members of the diet, in union with the representative of the emperor, had passed a resolution that those estates which had shown themselves favorable to the reformation should prohibit, until the convocation of an oecumenical council, all further innovations in religious matters, and in particular should not allow any alteration in the celebration of the Lord's supper or the mass. To this resolution the evangelical estates, consisting of the elector of Saxony, the margrave of Brandenburg-Anspach, the duke of Brunswick-Lüneburg, the landgrave of Hesse, the prince of Anhalt, and 14 imperial cities, refused to submit. They declared their readiness to obey the emperor and the diet in all "dutiful and possible matters;" but against any order considered by them repugnant to "God and his holy Word, to their souls' salvation and their good conscience," they entered, on April 19, a solemn protest. Henceforth they were called Protestants. The signers of the first protest did not fully agree in all their theological views; but they did agree in the protest against the authority of secular or ecclesiastical boards to compel obedience in matters of faith, and the name Protestant therefore came early into use as the collective name for all the Christian denominations in Switzerland, France, England, Scotland, Holland, and other countries which proclaimed the Bible to be the only rule of faith. (See Hauff, *Die protestantische Kirche in Deutschland*, Munich, 1861; Schenkel, *Das Wesen des Protestantismus*, 2d ed., Schaffhausen, 1862; Frank, *Ueber die Geschichte der protestantischen Theologie*, 2 vols., Leipsic, 1862-'5; De Félice, *Histoire des protestants de France*, Paris, 1870; and Wylie, "History of Protestantism," London, 1874 *et seq.*)—Protestantism is the predominant religion in all the countries of the Teutonic race, excepting the German provinces of Austria; in the United States of America, the German empire, Great Britain, Holland, Denmark, Sweden, Norway, Switzerland, and most of the colonial possessions of these states. The aggregate population connected with or under the influence of Protestant churches at the

close of 1874 is estimated in Schem's "Statistics of the World" (3d ed., 1875) as follows:

DIVISIONS.	Protestants.	Total population.
America.....	83,000,000	84,500,000
Europe.....	71,800,000	801,600,000
Asia.....	1,800,000	798,000,000
Africa.....	1,200,000	202,500,000
Australia and Polynesia..	2,200,000	4,400,000
Total.....	110,000,000	1,391,000,000

PROTEUS (Laurenti), or *Hypochthon* (Merr.), a perennibranchiate batrachian reptile, belonging to the same family as the axolotl and the menobranchus. The skin is naked and slimy, the body elongated and cylindrical, and the tail short, broad, and compressed laterally; the branchial tufts are three pairs, and persistent during life; legs four, rather weak, the anterior three-toed and the posterior four-toed. The common proteus (*P. anguinus*, Laur.) is about a foot long and half an inch in diameter; it is pale flesh-colored or white, with the branchial tufts bright crimson; the teeth are small and sharp, in both jaws and on the palate; the head triangular, and the snout obtuse; the eyes are very small, and without lids. It is found only in the subterranean waters of some caves of Europe, as in Carin-

Proteus anguinus.

thia and Tyrol, and especially in the Adelsberg cavern in Carniola. The respiration is essentially aquatic by means of the branchial tufts, though it has rudimentary lungs, rises to the surface to swallow air, and can live a short time out of the water, like the menobranchus; its motions by means of the legs are sluggish and awkward, but it swims rapidly and with ease by lateral undulations; when the water of its subterranean retreat becomes low, it buries itself in the mud; the food consists of aquatic worms and insects, and soft-shelled mollusks. Several local varieties occur, generally referred to the same species; one of these is purplish with yellow spots, and larger, widely extended, and coarsely divided gills; these are described as species of *hypochthon* by Fitzinger in the *Sitzungsberichte* of the academy of Vienna for October, 1850. (See **MENOBRANCHUS**.)

PROTEUS, in Greek and Roman mythology, a sea god subject to Neptune, whose flocks he tended. At midday he always arose from the flood and slept in the shadow of the rocks on the coast, and those who desired him to foretell the future were obliged to seize him at

that time. He would assume various shapes to terrify or disgust, and thus drive away his questioner; but when he found this subterfuge of no avail, he would yield to the demand.

PROTOGENES, a Greek painter, flourished toward the close of the 4th century B. C. He was born at Caunus in Caria, and for 50 years lived unnoticed and poor at Rhodes, until through the intervention of Apelles the Rhodians became aware of his merit. When Demetrius Poliorcetes besieged the city, he was careful not to attack the most defenceless part, because it contained the works of Protogenes. He spent so much time on his works, that Apelles said he never knew when to take his hand off. The "Ialysus" was considered his masterpiece, and this when Pliny wrote was preserved in the temple of Peace at Rome. Protogenes was also a statuary, and according to Suidas wrote on art.

PROTOPHYTES. See PROTOZOA.

PROTOPLASM (Gr. *πρῶτος*, first, and *πλάσμα*, form), a term applied to the supposed original substance from which all living beings are developed, and which is the universal concomitant of every phenomenon of life. All that is comprehended for brevity under the term life, whether the growth of plants, the flight of birds, or a train of human thought, is thus supposed to be caused by corporeal organs which either themselves consist of protoplasm, or have been developed out of it. Wherever nutrition and propagation, motion and sensation exist, there is as their material basis this substance designated in a general sense as protoplasm. The proof of it is held to be furnished by the protozoans called moners, the whole completely developed body of which consists solely of protoplasm. They are not only the simplest organisms with which we are acquainted, but also the simplest living beings we can conceive of as capable of existing; and though their entire body is but a single, formless, small lump of protoplasm, and (each molecule of it being like the other) without any combination of parts, yet they perform all the functions which in their entirety constitute in the most highly organized animals and plants what is comprehended in the idea of life, namely, sensation and motion, nutrition and propagation. By examining these moners we shall gain a clear conception of the nature of protoplasm, and understand the important biological questions connected with the theory. Some moners live in fresh water, and others in the sea. They are as a rule invisible to the naked eye, but some are as large as the head of a pin and may be distinguished without the aid of a microscope. When completely at rest a moner commonly assumes the shape of a simple sphere. Either the surface of the body is quite smooth, or numerous exceedingly delicate threads radiate from it in all directions. These threads are not permanent and constant organs of the slime-like body, but perishable continuations of it, which

alternately appear and disappear, and may vary every moment in number, size, and form. For this reason they are called false feet or pseudopodia. Nevertheless, by means of these pseudopodia the moners perform all the functions of the higher animals, moving them like real feet either to creep, climb, or swim. By means of these sticky threads they adhere to foreign bodies as with arms, and by shortening or elongating them they drag their own bodies after them. Each thread, like the whole body, is capable of being contracted, and every portion of it is as sensitive and excitable as the entire form. When any point on the surface of the body is touched with the point of a pin, or with another body producing a chemical alteration, as for example a small drop of acid, or when a current of electricity is passed through it, the threads are drawn in, and the entire body contracts into the form of a spherical lump. The same threads perform also the function of providing alimentation. When a small infusorium or any other nutritive particle comes accidentally in contact with the extended pseudopodia, these run quickly over it like a fluid, wind around it with their numerous little branches, fuse into one, and press it into the interior of the body, where all the nutritive portions are rapidly absorbed and immediately assimilated, while all that is useless is quickly ejected. The variations among the different moners, of which so far 16 kinds have been described (Haeckel's *Monographie der Moneren*), consist partly in the various forms of the pseudopodia, but especially in the different kinds of propagation. Some of them merely divide on reaching a certain size into halves; others put forth little buds which gradually separate from them; and others experience a sudden division of the mass into numerous small spherical bodies, each of which instantly begins a separate existence and gradually reaches the size of the ancestral organism.—The chemical examination of the homogeneous protoplasmic body shows that it consists throughout of an albuminous or slime-like mass, hence of that azotic carbonate of the character of the highly compounded connective group called proteine, albuminoids, or plasmon bodies. Like other chemical compounds of this group, protoplasm exhibits several reactions which distinguish it from all others. It is easy to detect it under the microscope, on account of the facility with which it combines with certain coloring matters, as carmine and aniline; it is colored dark yellow or yellowish brown by iodine and nitric acid; and it is coagulated by alcohol and mineral acids, as well as by heat. The quantitative composition of protoplasm, though in some cases greatly varying, resembles as a whole that of other albuminoids, and hence consists of from 50 to 55 per cent. of carbon, probably 6 to 8 of hydrogen, 15 to 17 of nitrogen, 20 to 22 of oxygen, and 1 to 2 of sulphur. Protoplasm possesses the quality of absorbing water in various quan-

ties, which renders it sometimes extremely soft and nearly liquid, and sometimes hard and firm like leather; but it is usually of a medium degree of density. Its more prominent physical qualities are excitability and contractility, which Kühne and others have made a special subject of investigation. On examining the numerous substances constituting the various organs of the higher animals with the microscope, it appears that they all consist of a large number of minute elements, known since Schleiden and Schwann (1838) by the name of cells; and in these cells protoplasm is the oldest, most primordial, and most important constituent. In every real cell there is, besides protoplasm, and while still alive and independent, a second important constituent, the cellular germ, so called (nucleus or cytoblast); but even this germ consists of an albuminous chemical compound which is closely related to protoplasm, and was originally produced from it by an exceedingly slight chemical alteration. The germ is usually a smaller and firmer formation within the protoplasm of the cell.—Inasmuch as the idea of an organic cell, as now adopted by histologists, rests on the presence of two different essential parts in this elementary organism, the internal cell and the external protoplasm, we must distinguish also two different kinds of elementary organisms: germless cytods, as moners for example, and the real germ-enclosing cells, which originate from the former by secreting in the interior of the small mass of protoplasm a true germ or nucleus. Cells of the simplest kind consist only of protoplasm with a nucleus, while in general the cells of animal or vegetable bodies have also other constituents, particularly and frequently an enclosing skin or capsule (the cellular membrane), also crystals, grains of fat, pigments, and the like, within the protoplasm. But all of these parts came into being only secondarily through the chemical action of protoplasm; they are but the internal and external products of protoplasm. (Haeckel's *Generelle Morphologie*, vol. i., p. 279.) The single cell of the simplest kind is able to exist as an independent organism. Many of the lowest plants and animals, and also many neutral *protista* (which are neither animals nor plants), retain for life the character of a simple cell. Such unicellular organisms of the simplest kinds are the *amebæ*, found in large numbers as well in fresh as in salt water. *Amœbæ* are simple naked cells of various and varying forms. The whole difference between them, especially *protamœbæ*, and certain moners, is that they have a germ. It is probable that this germ of the *amebæ* (as may be supposed to be the case with many and perhaps all other cells) is only an organ of propagation, and hence of heredity; while all the other functions, alimentation, motion, and sensation, are performed by the protoplasm. This seems to indicate that at the reproduction of the cells, which is usually effect-

ed by segmentation, it is the germ which first divides in two, and that the protoplasm afterward gathers around each of the two sister germs till it also falls in two. It is impossible to distinguish from the common *amœbæ* the cellular ovules of many of the inferior animals, as for example the sponges, medusæ, and other plant-like animals. With these the eggs are simple naked cells, which, with the sponges especially, sometimes crawl about independently in the body of the animal, giving rise to the idea that they were a class of parasitic *amœbæ*. But with other animals also, and with most plants, the eggs of which generally obtain subsequently special and often very complicated encasements and other additions, every egg is originally a simple cell. The seminal elements of the male are also only simple cells, and the entire mysterious process of fructification is after all nothing but the fusion or concrescence of two different cells, the one a female egg cell, and the other a male semen cell. In consequence of this fusion the germs of the two combined cells dissolve, and therewith the young, newly generated individual begins his existence as a simple cytod, or a small germless ball of protoplasm. But inside of this cytod soon arises a new germ, which turns it again into a cell, and this simple cell forms by oft repeated segmentation an accumulation of cells. Out of this heap are produced by secretion certain germinal layers or "germ leaves," and out of these proceed all the other organs of the complete being. Each of these organs again originally consists only of cells, and in all of these cells the essential constituent parts are only the germ and protoplasm: the germ as the elementary organ of propagation and heredity, protoplasm as the elementary organ of all the other functions, sensation, motion, alimentation, and adaptation. Cells and cytods, therefore, are true elementary organisms, independent minute forms of life, which either in the lowest existences continue to live independently, or in the higher organisms combine in numbers to form a community. Cells and cytods are the veritable "formers" of life, or plastids. The most ancient and primordial forms of plastids are cytods, the whole body of which consists of protoplasm, in which the germs are internally produced, and from which therefore the cells proceed.—As a matter of course, to the infinite varieties presented by the organic forms and vital phenomena in the vegetable and animal kingdom, corresponds an equally infinite variety of chemical composition in the protoplasm. The most minute homogeneous constituents of this "life substance," the protoplasm molecules, or plastidules, as they are called by Elsberg, must in their chemical composition present an infinite number of extremely delicate gradations and variations. The atoms of carbon, hydrogen, nitrogen, oxygen, and sulphur, which compose each of the plastidules, must enter into an infinite number

of diverse stratifications and combinations. The chemistry of to-day, with its imperfect methods of investigation, is totally powerless before these intricate organic compounds, and it is possible only to surmise, from the infinitely varied physiological qualities of the numberless kinds of plastids, the infinite variety of plastidules out of which they are composed. —According to the plastid theory recently advanced, the great variety of vital phenomena is the consequence of the infinitely delicate chemical difference in the composition of protoplasm, and it considers protoplasm to be the sole active life substance. This theory puts force and matter in living organisms into the same causal connection which has long been accepted for force and matter in inorganic bodies. This conception has been rapidly matured, especially in the past 20 years, through the more exact information obtained in regard to the lowest kinds of organisms. Yet the idea had been grasped more than half a century ago; for the "primordial slime" which Lorenz Oken proclaimed in 1809 to be the original source of life, and the material basis of all living bodies, possessed in all essentials the same qualities and the same importance now ascribed to protoplasm; and the *sarcode* so called, which in 1835 was pointed out by the French zoölogist Félix Dujardin as the only living substance in the body of rhizopods and other inferior primitive animals, is identical with protoplasm. But when Schleiden and Schwann, in 1838, developed their cell theory, they were not acquainted with the fundamental significance of protoplasm. Even Hugo Mohl, who in 1846 was the first to apply the name protoplasm to the peculiar serous and mobile substance in the interior of vegetable cells, and who perceived its high importance, was very far from understanding its significance in relation to all organisms. Not until Ferdinand Cohn (1850), and more fully Franz Unger (1855), had established the identity of the animate and contractile protoplasm in vegetable cells and the sarcode of the lower animals, could Max Schultze in 1858-'61 elaborate this protoplasm theory of the sarcode, so as to proclaim protoplasm to be the most essential and important constituent of all organic cells, and to show that the bag or husk of the cell, the cellular membrane, and the intercellular substances, are but secondary parts of the cell, and are frequently wanting. In a similar manner Lionel Beale (1862) distinguished such primary forming and secondary formed substances in all organic tissues, and gave to protoplasm, including the cellular germ, the name of "germinal matter," and to all the other substances entering into the composition of tissues, being secondary and produced, the name of "formed matter." The protoplasm theory received a wide and thorough illustration from the study of rhizopods which Ernst Haeckel published in 1862 in his *Monographie der Radiolarien*, and its complete

application in the *Generelle Morphologie der Organismen* by the same naturalist. Haeckel distinguishes in these works, for the first time, between germless protoplasm, consisting only of plastids called cytods by him, and the germ-containing real cells, the elementary organism of which consists already of two different essential parts, germ and protoplasm. He conceived the cytods and cells as two different gradations of plastids, of organic elementary individuals, or as "individuals of the first order," and adopted entirely, in regard to the individual independence of the plastids, the ideas which had been set forth by Rudolf Virchow and Ernst Brücke. Virchow, whose *Cellular-Pathologie* contains the most complete application of the cell theory to pathology, called the cells and the "cell territories" belonging to them the individual hearth or source of life; Brücke designated them as "elementary organisms." The plastids or individuals of the first order, identical with them, were determined by Haeckel phylogenetically, to the effect that cytods and cells must be distinguished as two essentially different orders of formation; *i. e.*, that cells were phylogenetically produced in a secondary manner from homogeneous cytods by means of the secretion of a germ by the protoplasm. This distinction is important for the reason that many of the lowest orders of organisms have no germ in the protoplasm; such is the case especially with the moners. These simplest of organisms were first discovered by Haeckel in 1864, and described by him in 1868 in his *Monographie der Moneren*. Cienkowski and Huxley also made valuable investigations of various moners. The latter discovered in 1868 the famous bathybius, a very remarkable kind of moner, which at immense depths covers the bottom of the sea in immeasurable numbers, and which consists of formless and variable protoplasm tissues of different sizes. Among the moners investigated by Cienkowski, the most interesting are the vampire cells, which are formless little bodies of protoplasm that bore into vegetable cells by means of their pointed pseudopodia, kill them, and absorb the protoplasm they find in them. On the basis of these discoveries Haeckel elaborated his plastid theory and carbon theory, which give the extremest philosophical consequences of the protoplasm theory.—In England the monistic philosophy of protoplasm has received the most weighty support from Huxley, whose "Protoplasm, or the Physical Basis of Life" (1868), put it in its true light, and called forth numerous writings for and against it. One of the most recent treatises in favor of it is that of James Ross "On Protoplasm" (1874). Probably the name of plasson will be given to the primordial, perfectly structureless, and homogeneous protoplasm of the moners and other cytods, in contradistinction to the protoplasm of germ-containing cells, which are produced only subsequently, by the differentiation of an

internal nucleus and external protoplasm by the plasson bodies of moners. Édouard van Beneden especially calls for this distinction in his *Recherches sur l'évolution des grégaires*; and Haeckel has adduced new facts in favor of it in his *Monographie der Kalkschwämme*. For the theory of "primordial generation," the spontaneous generation of the first vitality on earth, the distinction is of special importance, as the first organisms thus produced could have been only structureless specks of plasson, like the bathybius and other moners. The great theoretical difficulties formerly in the way of the theory of primordial or spontaneous generation have been removed by the discovery of the moners and the establishment of the plastid theory. As the protoplasm of the bathybius is not yet as much as individualized, while in the case of other moners there are individual lumps of constant sizes, it follows that the moners are to be regarded as the natural bodies which effect the transition from inorganic to organic nature.—The following list of publications gives the literature of the important discoveries in this field in chronological order: Hugo Mohl, *Ueber die Saftbewegung im Innern der Zelle* (in *Botanische Zeitung*, 1846); Ferdinand Cohn, *Nachträge zur Naturgeschichte des Protococcus pluvialis* (in *Nova Acta Naturæ Curiosorum*, 1850); Hugo Mohl, *Grundzüge der Anatomie und Physiologie der vegetabilischen Zelle* (1851); Franz Unger, *Anatomie und Physiologie der Pflanzen* (1855); Max Schultze, *Innere Bewegungerscheinungen bei Diatomeen* (in Troschel's *Archiv für Naturgeschichte*, 1860), *Die Gattung Cornuspira unter den Monothalamien*, &c. (1860), and *Ueber Muskelkörperchen und das was man eine Zelle zu nennen habe* (1861); Ernst Brücke, *Elementar-Organism* (in *Sitzungsberichte der Wiener Akademie*, 1861); Ernst Haeckel, *Die Sarcode der Radiolarien: Monographie der Radiolarien* (1862); Lionel Beale, "The Structure of the Simple Tissues of the Human System" (1862); Max Schultze, *Das Protoplasma der Rhizopoden und der Pflanzenzellen* (1863); Haeckel, *Ueber den Sarcodkörper der Rhizopoden* (*Zeitschrift für wissenschaftliche Zoologie*, 1864); Wilhelm Kühne, *Untersuchungen über das Protoplasma und die Contractilität* (1864); Haeckel, *Generelle Morphologie der Organismen* (1866), and *Monographie der Moneren* (in *Jenaische Zeitschrift für Naturwissenschaft*, 1867); Huxley, "Protoplasm, or the Physical Basis of Life" (1868), and "On some Organisms living at Great Depths in the North Atlantic Ocean" (in "Journal of Microscopical Science," 1868); Haeckel, *Beiträge zur Plastiden Theorie* (in *Jenaische Zeitschrift*, 1870); Rudolf Virchow, *Die Cellularpathologie in ihrer Begründung auf physiologische und pathologische Gewebelehre* (4th ed., 1871); Édouard van Beneden, *Recherches sur l'évolution des grégaires* (in *Bulletin de l'Académie royale de Belgique*, 1871); Haeckel, *Monographie der Kalkschwämme* (1872); James Ross, "On Pro-

toplasm" (London, 1874); John Drysdale, M. D., "The Protoplasmic Theory of Life" (1875); and H. Charlton Bastian, "Evolution and the Origin of Life" (1875). "As regards Protoplasm," by J. H. Stirling (Edinburgh, 1869), is intended as a refutation of the theory.

PROTOZOA (Gr. *πρῶτος*, first, and *ζῶον*, animal), a subdivision of invertebrate animals, proposed by Siebold, since adopted by Leuckart and Vogt, and now generally admitted by naturalists. As they include the lowest and in most cases the most microscopic of animals, the limits of this division are not well defined; they comprise many of the so-called animalcules, as well as the large sponges. They are composed of a nearly structureless, jelly-like substance, called protoplasm or sarcode, without distinct segments, internal cavity, or nervous system, and with no or a very rudimentary digestive apparatus. (See PROTOPLASM.) Dr. Engelmann has observed in *arcella*, a minute amœba-like protozoan, a periodical development of gas in the granular protoplasm, unconnected with the contractile vacuoles or the nuclei. He thinks this is a voluntary act, and that the bubbles are used in the manner of a float or air bladder. Its chemical composition and the mechanism of its production and absorption were not determined. The usually accepted division is into the classes of *gregarinida*, *rhizopoda* (like amœbæ, foraminifers, and sponges), and *infusoria*, the highest, with a mouth and digestive apparatus, like the bell animalcules and *paramœcium*. As these represent the first step in animal organization, so do the protophytes the first in vegetable life; the former were called *oözoa* by Carus, from their resemblance to the ova or germs of higher animals; the latter, as far as known, were microscopic seaweeds, without the radiate structure characteristic of plants, and are found in the lower Silurian strata. (See ANIMALCULES, BATHYBIUS, COCCOLITHS, FORAMINIFERA, GLOBIGERINA, and GREGARINA.)—See Prof. Packard on the "Development of Protozoa," in the "American Naturalist," December, 1874, to February, 1875.

PROTRACTOR, an instrument for laying off angles in plotting. There are four principal forms of the protractor: the rectangular, the semicircular, the circular, and the reflecting. The rectangular consists usually of a thin rectangular piece of ivory or metal, three edges of which are graduated from 0 to 180 degrees by portions of radii converging to the middle of the fourth edge as a centre; it is used only where a loose approximation to accuracy suffices. The circular and semicircular protractors, with either two, one, or no arms, are graduated circular arcs (usually metal), with or without flat straight-edged arms, turning about their perforated centres, and carrying verniers for the accurate reading of their arcs. But as they are only capable of protracting and measuring single angles on a map, they have not so wide a range of usefulness in engineering and sur-

veying as the three-arm protractor. The three-arm circular protractor is a modification of the station-pointer, differing from it in having its verniers movable and its arcs fixed, instead of the opposite. It consists of a graduated circular arc fixed to the middle one of three long flat arms which turn about its centre, from which diverge their straight fiducial edges. Fixed to each of the side arms is an index and vernier, by means of which those arms can be set so as to make any required angles with the middle arm. This instrument furnishes the readiest and most accurate graphic solution of the three-point problem on which hydrographers so universally depend for determining positions of the sounding boat. The reflecting protractor, invented in January, 1874, by T. J. Lowry of the United States coast survey, enables one observer to measure at the same instant two adjacent angles, and plot them with the same instrument. It is obtained by placing between the fixed and each of the movable arms of the three-arm protractor an index arm; and each of these is so connected with those by means of jointed parallelograms that it always bisects the angle contained by the fixed arm and its corresponding movable protractor arm. Each of these index arms carries a mirror mounted perpendicular to its plane (and over its centre) of motion; these mirrors may be mounted to move either in the same or in parallel planes. (See *SEXTANT*.) Slightly forward of these mirrors on the line of sight is fixed a horizon glass, half silvered to admit of direct and reflected vision. As the angular distance moved over by a mirror while measuring an angle is only half of the actual angle measured, and as each of these movable protractor arms is driven along its arc simultaneously with and twice as fast as its corresponding index arm, the angles contained by the fixed and movable protractor arms are the actual angles measured. When using the reflecting protractor the observer brings its face into the plane passing through his eye and three objects, and then sets his index arm so that the reflected and direct images of the objects (say left-hand and middle) of one of the desired angles are not coincident, yet approaching on account of the progress of the boat, and with the second index glass he makes the images of the right-hand and middle objects coincident, and keeps them so with the tangent screw till the first two objects become coincident, then clamps, and the angles are measured and also ready set off on the instrument. He now places the instrument on the map and shifts it until the fiducial edges of its protractor arms traverse the three points observed on, and dots the centre of the position.

PROUDHON, Jean Baptiste Victor, a French jurist, born at Chansans, Franche-Comté, Feb. 1, 1758, died in Dijon, Nov. 20, 1838. During the revolution he was judge at Pontarlier and assistant deputy to the legislative assembly, and afterward a member of the civil tribunal at

Besançon. In 1802 he delivered free lectures on law; in 1806 he was appointed professor of civil law in the school of Dijon, and in 1809 became dean of the faculty. His principal works are: *Traité sur l'état des personnes et sur le titre préliminaire du Code civil* (1810); *Traité des droits d'usufruit, &c.* (9 vols., 1823-'6); and *Traité du domaine public* (5 vols., 1834-'5).

PROUDHON, Pierre Joseph, a French political writer, born in Besançon, July 15, 1809, died at Passy, Paris, Jan. 19, 1865. He was educated at the college of his native city, became apprentice to a printer, and in 1837 was taken into partnership by a printing firm at Besançon. He published an edition of the Bible with annotations upon the principles of the Hebrew language, and reprinted Bergier's *Éléments primitifs des langues* (1837), with an anonymous *Essai de grammaire générale*, by himself, as an appendix. This essay received from the academy of Besançon a prize consisting of a triennial pension of 1,500 francs, which enabled him to visit Paris. Here he became a contributor to Parent Desbarres's *Encyclopédie catholique*, and wrote for the Besançon academy a prize essay, *De la célébration du dimanche* (1840), and a paper entitled *Qu'est-ce que la propriété?* This pamphlet, which opened with the afterward celebrated dictum, *La propriété c'est le vol*, was censured by the academy, who at once cut short Proudhon's allowance; but the economist Blanqui, who had been appointed to examine it, declared that he found nothing objectionable in it. It was followed in 1841 by another pamphlet on the same question, and in 1842 by an *Avertissement aux propriétaires*, for which he was arraigned before a jury at Besançon, but was acquitted. In the same year he went to Lyons, and from 1843 to 1847 was director of a company running freight boats on the Saône and Rhône. In the mean time he continued to propagate his opinions in *De la création de l'ordre dans l'humanité* (1843), presenting the theory of a new political organization, and *Système des contradictions économiques* (2 vols. 8vo, 1846). On the breaking out of the revolution of February, 1848, he was in Paris engaged in the publication of his *Solution du problème social*, a plan of social reform by means of a new organization of credit and monetary circulation. On April 1 he became the editor of *Le représentant du peuple*, a daily journal of radical opinions, suspended in August. On June 4 he was elected deputy to the constituent assembly, and on July 31 he came forward to urge a proposition which he had previously made for the establishment of a progressive income tax, the design of which was the abolition of interest on capital, and eventually the consolidation of the republican government. This was almost unanimously voted down "as an odious attack upon the principles of public morality and an appeal to the worst passions." He closed his parliamentary career

by opposing (Nov. 4) the adoption of the constitution, which he looked upon as "dangerous to liberty." He next edited in succession three short-lived journals, the last of which expired Oct. 13, 1850. These papers were repeatedly condemned by the courts, but the fines imposed upon the editor were immediately paid by his admirers. His printed speeches and pamphlets, including his *Droit au travail* (1848), *Les Malthusiens, Démonstration du socialisme*, and *Idées révolutionnaires* (1849), found a ready sale among men of all opinions, and elicited answers from the ablest pens in the conservative party. In January, 1849, he had undertaken to establish *la banque du peuple*, an institution of gratuitous credit, by means of which he hoped to bring his theory into operation; but in this he was interrupted, March 28, by a sentence of three years' imprisonment for illegal publications, which he at first avoided by flight. After sojourning in Geneva for a few months, he delivered himself up (June 4), and was incarcerated successively in the Conciergerie, at Doullens, and in the prison of Ste. Pélagie, where in 1850 he married a merchant's daughter. During his imprisonment he wrote *Confessions d'un révolutionnaire* (1849), *Actes de la révolution* (1849), *Gratuité du crédit* (1850), and *La révolution sociale démontrée par le coup d'état* (1852), which created a deep sensation and was looked upon as a partial apology for Napoleon's policy. He was liberated on June 4, 1852; in 1856 published a *Manuel des opérations de la bourse*, a satire on stockjobbers and speculators; and soon afterward *De la justice dans la révolution et dans l'église, nouveaux principes de philosophie pratique* (3 vols., 1858), which he ironically dedicated to the archbishop of Besançon. This metaphysical work, a covert attack upon the established order of things, was seized by the police, and its author was sentenced to three years' imprisonment and a fine of 4,000 francs; but Proudhon was in Belgium, where he remained till November, 1860, when the amnesty granted to the press by Napoleon III. permitted him to return to Paris. His principal later works are: *La guerre et la paix* (2 vols., 1861); *Théorie de l'impôt* (1861); *La fédération et l'unité en Italie* (1862); and *Du principe fédératif et de la nécessité de reconstituer le parti de la révolution* (1863). Among his posthumous works are: *Les Évangiles annotés* (1865), which was seized and the editor was sentenced to a year's imprisonment; and *France et Rhin* (1867).—See *Proudhon, sa vie, ses œuvres et sa correspondance*, by Charles Clément (1872). The first volume of his correspondence was published in 1874, and is to be followed by seven others, besides several additional posthumous works.

PROUT, Father. See MAHONY, FRANCIS.

PROUT, Samuel, an English water-color painter, born in Plymouth, Sept. 17, 1783, died in London, Feb. 10, 1852. Some sketches of Cornish scenery which he executed for Britton the

antiquary first brought him into notice, and in 1805 he removed to London. He published a series of studies executed in lithography (1816); "Facsimiles of Sketches made in Flanders and Germany;" "Sketches in France, Switzerland, and Italy;" "Antiquities of Chester;" "Hints on Light and Shade, Composition, &c., as applicable to Landscape Painting;" "Microcosm, the Artist's Sketch Book of Groups of Figures, Shipping, and other Picturesque Objects;" and "Hints for Beginners."

PROUT, William, a Scottish physician, born in 1786, died in London, April 9, 1850. He received his professional education at the university of Edinburgh, but passed the greater part of his life in London. His researches on the application of chemistry to the explanation of the phenomena of life are contained in an important work "On the Nature and Treatment of Stomach and Renal Diseases" (5th ed., 1848). He also published "An Inquiry into the Nature and Treatment of Gravel" (1821); "Chemistry, Meteorology, and the Function of Digestion, considered with reference to Natural Theology," a Bridgewater treatise (1834; 4th ed., 1855); and a number of papers in scientific magazines and transactions.

PROVENÇAL LANGUAGE AND LITERATURE.

Provençal belongs to the Romance or Romanic group of the Aryan or Indo-European family of speech. (See ROMANCE LANGUAGES.) Its real home is the south of France, the boundary line running through Dauphiny, Lyonnais, Auvergne, Limousin, Périgord, and Saintonge. It is spoken also in the east of Spain, Catalonia, Valencia, and the Balears, and in Savoy and a portion of Switzerland. At present several dialects may be distinguished: New Provençal, Languedocian, Limousinian, Auvergnian, Dauphinese, Waldensian, Gascon, and Catalan. The Provençal language separated from the idiom of northern France, designated as *la langue d'oïl*, from the use of the affirmation *oïl* (Lat. *illud*), about the beginning of the 9th century. Probably there was once but one Romance language in the whole of Gaul, though some of the early literary monuments which are generally produced as examples of the original uniform tongue, also dating from the 9th century, have a preponderance of French forms. In order to distinguish the newly formed dialect of the south of France from Italian, Spanish, and French, and to give it a geographically comprehensive name, it was natural to select for it the name of the largest province within its territory. Thus, in distinction from *romana*, came into use *la lingua proensal*, *la proenzal*, *le proensalès*, and *vulgar proensal*; and the people who spoke it were called *Provinciales*, though also *Francigenæ*. It received also the name of Limousinian (*lemosin*), after the province of Limousin, which was gradually transferred also to the Catalan-Valencian idiom. As a large part of southern France came to be called Languedoc or Llenquadoch, after the use of the affirmation *oc*

(Lat. *hoc*), which is the origin also of the middle Latin name Occitania and of the French adjective *occitanien*, later writers fell into the habit of applying the name of *langue d'oc* to the whole Provençal language, while it should be strictly confined to the Occitanian dialect. The middle of the 10th century furnishes the first monument of the Provençal language, but its principal development occurred in the 12th and 13th centuries, the flourishing period of the peculiar poetry of the troubadours. But as early as the middle of the 13th century the language ceased to be used by the higher classes. As the troubadours took particular pains to ridicule the clergy and the practices of the church, they drew upon themselves the ill will of the ecclesiastical party, and in 1245 Innocent IV. issued a bull in which he called Provençal the language of heretics, and forbade its use by students. The wars which during the early part of the 13th century desolated the south of France were also fatal to the language. The troubadours sought refuge at the court of Aragon and in Catalonia, and kept the language for a time from corruption; but by the beginning of the 14th century Provençal generally succumbed in Spain also to the adjacent dialects. An attempt was made to preserve the language by establishing consistories of the "gay science" in Toulouse and Barcelona, but their success was short. In Italy, in the northwest of which it was spoken, it was quickly forgotten on the revival of the ancient literature, and was superseded by Tuscan. The language thus passed into dialects spoken only by the peasantry in its former territory, and its use for poetical composition has come to be only a matter of caprice.—Provençal is the earliest Romance language which received grammatical treatment; but the object was only to check the carelessness of expression on the part of the poets, and thus to counteract the threatening decadence of the language. Provençal scarcely ever developed into a uniform literary language, as the poets lived at the various courts. But the efforts on the part of the troubadours to attain a certain elegance, ease, and variety of diction, causing them to reject many expressions as inelegant and impure, led to the formation of a choicer language than that used by the masses, which was called *lo dreg proensal*, or *la dreita parladura*; this was not peculiar to any one province, though not without provincialisms. The want of an orthography, and the indefiniteness of the dialectical variations, render it very difficult to determine either the pronunciation or the construction of the language. The grammatical treatises of Uk Faidit and Raimon Vidal hardly touch upon these subjects. They contain discourses on long and short syllables, and there is an attempt to show the difference of pronunciation between French and Provençal. Only the *Lays d'amors* makes frequent reference to the value of the letters and to orthography. The

forms *fau* and *fatz*, *plai* and *platz*, *faire* and *far*, *conques* and *conquis*, *ditz* and *di*, and the like, are used for the same words by one poet, and the rhymes follow accordingly; yet such instances cannot be cited to prove that *quar* (Lat. *quare*) was pronounced differently from *car*, or *altre* otherwise than *autre*; for *quar* and *altre* may have been written according to etymology, while *car* and *autre* represented the pronunciation. Accordingly but little is said in modern philological works on Provençal about the pronunciation of it. When Raynouard, the great student of the *langue d'oc*, was interrogated in regard to it, he replied: *Il n'y a pas de prononciation provençale* ("There is no Provençal pronunciation"); and Diez, who has given the fullest treatise on Provençal vowels and consonants, admits that there is a great amount of truth in the reply.—The characteristics of the modern Provençal dialects are the following. In the New Provençal many words ending in *e* in French have *i*, as *agi*, *couragi*; *au* is generally sounded *ou*; *l* is changed into *u* and *ll* (as in *filles*) into *y*; and *c* before *a* is sometimes guttural and sometimes palatal. The Occitanian dialects of Languedoc resemble New Provençal very closely. In Toulouse *oi* is sounded instead of *ei*; in Montpellier, *io* for *ue*; the letter *l* is not always changed into *u*; final *n*, preserved in Montpellier, is dropped in Toulouse; Latin *et* and *di* change into *ch*, and *v* into *b*. The Limousinian dialect may be divided into Upper and Lower Limousinian. In the latter *a* is generally sounded as *o*, *ai* as *ei*, *ieu* as *iou*, *ch* as *ts*, *j* and soft *g* as *dz*. In Auvergne *ai* becomes *oue*; *oi*, *eu*; *eu* and *iu*, *iau*; final *l* and *n* disappear; *s*, *g*, and *z* often become palatals; *ch* is sounded as in French, and final *c* as *t*; *l* often becomes *r*. In Dauphiny, especially at Grenoble, the influence of the French pronunciation becomes more apparent, while the Waldensian dialect has experienced some changes through the influence of Italian. In fact, we may doubt whether the latter has been directly derived from Provençal, though the early Waldensian literary monuments betoken a near kinship to it. Gascon still shows its Provençal origin, but it has absorbed so many foreign elements that its parentage is greatly obscured. Prominent among its peculiarities are the preceding of *r* by *a*, opening *ll* for *l*, internal *r* for *l*, *ch* for *s* and *ss*, *qua* sounded with an audible *u*, *b* for *v*, and *h* for *f*. Catalan is properly not a dialectical variation of Provençal, but rather an independent idiom closely related to it. Its peculiarities are the change of mute *e* into *a*; the preservation of *e* and *o* without change into diphthongs; the absence of *ie*, *ue*, *iei*, *ieu*, and the rare use of other diphthongs and triphthongs; the softening of *l* into *ll*; the dropping of Latin final *n*; the palatal sounds of *g*, *j*, and *x*; *ch* in the beginning of words for *c*; the sound of *z* for *c*; and the audible *u* in *qua* and *gua*. Valencian is almost the same as Catalan,

only somewhat softer in pronunciation.—The first monument of the Provençal language belongs to the middle of the 10th century. It is a fragment of 257 ten-syllable verses on Boëthius, and has been preserved in a manuscript of the 11th century, which, according to Paul Meyer, and as appears from the language and mode of writing, originated in Limousin or Auvergne. Next in historical order come a few partly Provençal poems, including a long poem on the passion of Christ, and the legend of St. Leodegar, published in Champollion-Figeac's *Documents historiques*. Raynouard has collected several Latin documents with sentences of Provençal interspersed, dating from about 860 to 1080; and other documents in part or entirely Provençal, of a later date, have been embodied in Bartsch's *Chrestomathie*. Several minor poems on religious subjects and several sermons, dating from about the 11th century, have been collected by Paul Meyer. Of the same date, or perhaps of the beginning of the 12th century, is a manuscript recently published by Konrad Hoffmann, containing a paraphrase of the discourse of Christ in John xiii. The main feature of the flourishing period of Provençal literature is the poetry of the troubadours. According to Quiraut Riquier, it would seem that the troubadours were in a measure the successors and disciples of the *jongleurs*, who made a sort of trade of rhyming and singing and dancing. Some account of the *art de trobar* (art of inventing) is necessary for an adequate idea of the main characteristic of Provençal poetry. In one class of versification, the *canson* (*canzo*, *canzoneta*), the rhymes, pauses, and general manner of the first stanza had to be maintained through all the succeeding stanzas, and at the close came a *commiato*, or summary of the whole, addressed by the poet to his friends, patrons, or mistress. The *servente* permitted greater ease of composition, and while the *canson* was used chiefly for moral and amorous effusions, the office of the latter poetic form was to serve as a vehicle for attacks on the secular and spiritual lords, as well as for love songs of a satirical or light nature. In the *tensons*, or poetic combats, two or more persons support opposite sides on some subject of philosophy or love. Though these combats were originally extemporary, in later times several troubadours would choose a common subject and metre; the first would compose a stanza and transmit it to another, who would compose the second stanza, and so on; and when each of the disputants had added his part, the whole would be submitted to competent judges, forming what was called a "court of love." There are also epistolary treatises on the subjects of love, friendship, and chivalry, which were called *donaire*, *sautz*, and *ensenhamen*. The *planh* is a kind of elegy celebrating the memory of a fallen knight, or mourning over disappointments in love. Little poems sung during the dance were

called *balada* and *dansa*; they were mostly of a very simple nature. The *serena*, serenade or evening song, gives utterance to the most passionate love, but only one has come down to us. The *alba*, or waking song, reminds the lovers that it is dawn. The *pastoreta* or *pastorela* generally gives a conversation held between a knight and a shepherdess, one complimenting the other, and always on the subject of love.—The earliest troubadour of whom any poetic remains have been preserved is William IX. of Poitiers (1071–1127). Among the most important Provençal poets subsequent to him must be mentioned first of all Giraud de Bornel (1170–1220), who in the opinion of his contemporaries was the greatest of all. Richard Cœur de Lion of England, Alfonso II. of Aragon, and Robert I. of Auvergne were also celebrated troubadours. They were excelled, however, by Bertrand de Born, their contemporary, whom Dante and Uhland would have immortalized if his own fiery and warlike rhymes had not. Other famous troubadours toward the end of the 12th century were Marcabrun, Jaufre, Randal, Count Rambaut III. of Orange, Peire of Auvergne, Peire Rogier, Peire Raimon of Toulouse, Arnaut de Marueil, Peire Vidal, Rambaut de Vaqueiras, Peirol, the monk of Montauban, and Arnaut Daniel. To the 13th century belong the names of Faidit, Raimon of Miraval, Savarik of Mauléon, Uk of Saint Cyr, Aimerik of Peguilain, Peire Cardinal, Guillem Figueiras, Sordel, Bonifaci Calvo, Bertolome Zorzi, and Quiraut Riquier. Among the treatises on the troubadour's art stands foremost *La dreita maniera de trobar*, "The Correct Art of Versifying," by Raimon Vidal, who seems to have been a famous troubadour of the middle of the 13th century. Another, but more of a grammatical nature, is the *Donatus Provincialis* by Uk Faidit, extant in two editions, one Romance, the other Latin; both have been published in Guessard's *Grammaires romanes inédites*. A full grammar and science of poetry was published by the consistory *del gay saber* of Toulouse, and edited by Moulinier, entitled *Leys d'amors*, "Laws of Love," i. e., of the poetry of love. A portion of it, *Las flors del gay saber*, appeared in 1356. But by this time Provençal verse was almost extinct. The troubadours had lost their most eminent patrons, and the attempt to revive them by distributing prizes for the best composition in the floral games of Toulouse failed to establish the name of any Provençal poet. Still, there have always been some who used Provençal for their poetic compositions, and in the 19th century several have even gained celebrity as Provençal poets. Foremost among these stands Jacques Jasmin, the barber of Agen (1798–1864), and after him come José Roumanille, Théodore Aubanel, and the marquis de la Fare-Alais. The most eminent living Provençal poet undoubtedly is Frédéric Mistral, the pupil of Roumanille, and one of the largest contributors to *Li Prouvençalo*

(1852), a collection of modern Provençal poetry. His fame rests principally on his charming rustic epic entitled *Mirèio* (1859), translated by himself into modern French (*Mireille*), and set to music by Gounod, and of which there are versions in English by H. Crichton and by Harriet W. Preston.—The earliest writers on the Provençal literature were Cardinal Bembo and Jean de Nostre Dame, or Nostradamus, brother of the astrologer. Nostre Dame collected a large number of manuscripts, and composed a work on the lives and writings of the old Provençal poets. Lacurne de Sainte-Palaye expended a vast amount of time and labor in ransacking the libraries of France and Italy, and collecting materials on the subject, which the abbé Millot published under the title of *Histoire littéraire des troubadours* (3 vols., Paris, 1774; abridged English translation by Mary Dobson, London, 1779). But it is chiefly to M. Raynouard, a native of Provence, that we are indebted for our knowledge of the Provençal. In his *Choix des poésies originales des troubadours* (6 vols., Paris, 1816-'21), he published vestiges of their early poetry, and lives and extracts from the writings of about 350 poets. Previously he had written a grammar of the language (1816), and to this he added a lexicon which appeared after his death (6 vols., 1838-'44). In his footsteps followed Charles Claude Fauriel, whose *Histoire de la poésie provençale* (3 vols. 8vo, Paris, 1846; abridged English translation, New York, 1860), delivered in a series of lectures as professor in the faculty of letters at Paris, is the most elaborate work on the subject upon which it treats. In Germany the study of Provençal received a scientific foundation at the hands of Friedrich Diez, whose *Die Poesie der Troubadours* (Zwickau, 1826) and *Leben und Wirken der Troubadours* (1829) have been translated into French and English. See also Mahn, *Die Werke der Troubadours in provenzalischer Sprache* (Berlin, 1846 et seq.), *Die Biographien der Troubadours* (1853), and *Gedichte der Troubadours* (4 vols., 1856-'68); Paul Meyer, *Anciennes poésies religieuses en langue d'oc* (Paris, 1860), *Cours d'histoire de la littérature provençale* (1865), and *Recueil d'anciens textes bas-latins, provençaux et français* (1873 et seq.); Böhmer, *Die provenzalische Poesie der Gegenwart* (Berlin, 1870); Karl Bartsch, *Grundriss zur Geschichte der provenzalischen Literatur* (1872), and *Chrestomathie provençale* (Paris, 1875); and Rutherford, "The Troubadours: their Loves and their Lyrics" (London, 1873).

PROVENCE, an ancient province of S. E. France, bounded N. by Dauphiny and Venaisin, E. by the Alps, S. by the Mediterranean, and W. by Languedoc. It was a part of the territory to which the Romans gave the name of Provincia, and was divided into Upper and Lower Provence, watered by the Rhône, Durance, and Var, and celebrated for its delightful climate and rich fruits, though the soil

is somewhat arid. Its capital was Aix. It now forms the departments of Basses-Alpes, Bouches-du-Rhône, and Var, and a part of those of Drôme, Vaucluse, and Alpes-Maritimes.—This territory passed into the hands of the Visigoths in the 5th century, and of the Ostrogoths in the 6th, and, after being for a while in the possession of Austrasia, fell to Lothaire on the division of the empire of Charlemagne. In the latter part of the 9th century it formed part of Cisjurane Burgundy, and in the 10th of the kingdom of Arles, which was subsequently united to Germany; but Provence meanwhile was governed by virtually independent counts, who about 1063 became hereditary. In the middle of the 13th century it passed by marriage into the possession of Charles of Anjou, afterward king of Naples. The last count, Charles, grandson of René the Good, bequeathed it in 1481 to Louis XI., and it was united to the crown of France by Charles VIII. in 1486.

PROVERBS, a book of the Old Testament, entitled in the Hebrew original as well as the Septuagint and the Vulgate "The Proverbs of Solomon." Its real or final authorship, however, is not ascribed to Solomon, for it is expressly stated at the opening of chapter xxv. that the latter part, beginning with that chapter, was written and added to the previous portion by order of King Hezekiah. Moreover, it is considered doubtful whether Solomon ever made any collection of his proverbs in writing. But it has hardly ever been contested that a large share in the composition of the book may be ascribed to the wise king, who is said (1 Kings iv. 32) to have uttered 3,000 proverbs, and who was so celebrated all over the eastern world for his wisdom. The ancient writers of the Greek church frequently gave to this book the name *Sophia* (wisdom).—The book is divided into several parts, which are distinguished from each other by separate headings. The first seven verses of the first chapter may be regarded as a heading for the entire book. Then begins the first part, closing with the end of the ninth chapter. This part does not contain a collection of proverbs proper, but rather a series of connected admonitions in a sententious form. They inculcate the love of wisdom, and describe the glorious reward of wisdom and the pernicious consequences of wickedness. The second part, which extends from chap. x. to xxii. 16, contains the main collection of proverbs and the chief portion of the entire book. The proverbs, about 400 in number, contain moral precepts and rules of life for every age and every class of men. Generally one proverb is comprised in one short verse, of two members or clauses, and six, seven, or eight words. The two members form a parallel opposition, or occasional correspondence, to each other, which is generally carried out even to the single expressions; as for example x. 1 (rendering the Hebrew literally):

A-wise son	gladdens	(his) father.
A-foolish son	(is) the-grief	of-his-mother.

The grouping together of the proverbs in this part appears to have been accidental, except that occasionally two or three verses follow each other which have a characteristic expression in common. With xxii. 17 a kind of appendix begins. The proverbs of this section generally consist of two verses, and sometimes of three; they are constructed with less regularity, sometimes containing more than two members, and often without any parallelism. Sometimes proverbs of kindred contents are grouped together. A second appendix to the first collection begins at xxiv. 23, and is separated from the preceding by the heading, "These also are from wise men" (in the common English version, "These things also belong to the wise"). —The second main collection begins with chapter xxv., which is headed, "These are also proverbs of Solomon, which the men of Hezekiah, king of Judah, copied out." The proverbs, as in the first collection, consist generally of one verse each, and each verse of two or more members with parallel relation; yet exceptions to this rule occur more frequently than in the first collection. The proverbs of the second collection are not so plain and intelligible as those of the first, but more artificial and frequently even enigmatical. This collection extends over five chapters, and is again followed in the last two chapters of the book by three different appendices. —It is impossible to decide whether the compilation and arrangement of the entire book were made at one time by one man, or whether the addition of the several parts took place at different periods. The advocates of the former opinion adduce in their favor, that the arrangement of the whole seems to rest on a well conceived and thoroughly executed plan. In either case it is considered probable that the book received its present form between the time of the death of King Hezekiah and the end of the 7th century B. C. —There are commentaries on this book by Salazar (1641), Schultens (1748), Hodgson (1788), Lawson (1821), Umbreit (1826), Ewald (in vol. iv. of his *Die poetischen Bücher des Alten Bundes*); Bertheau, *Exegetisches Handbuch* (1847); Hitzig, *Die Sprüche Salomo's* (1858); Wardlaw (2 vols., 1860-'61); Kamphausen, in Bunsen's *Bibelwerk* (1865); Zöckler, in Lange's *Bibelwerk* (1867; translated for the American edition by Dr. Aiken, 1870); Delitzsch (1873), and others. German translations are added to the commentaries of Umbreit, Ewald, Hitzig, Kamphausen, Zöckler, and Delitzsch. There is an English translation, with *Ecclesiastes and Canticles*, by Noyes (Boston, 1846; 3d ed., 1867); and a revised version, with critical and explanatory notes, by Conant (New York, 1872).

PROVIDENCE, the N. county of Rhode Island, bordered N. and E. by Massachusetts and W. by Connecticut, and drained by the Blackstone river, which runs partly along the E. border, and the Pawtuxet, which forms a portion of

the S. boundary; area, 380 sq. m.; pop. in 1870, 149,190. It has an uneven surface and generally fertile soil. It is intersected by several railroads centring at Providence. The chief productions in 1870 were 9,887 bushels of rye, 85,114 of Indian corn, 15,386 of oats, 9,900 of barley, 329,515 of potatoes, 38,606 tons of hay, 3,330 lbs. of wool, 296,128 of butter, and 30,235 of cheese. There were 3,323 horses, 8,056 milch cows, 1,369 working oxen, 3,655 other cattle, 1,667 sheep, and 6,612 swine. There are numerous manufactories, chiefly at Providence, the county seat.

PROVIDENCE, a city, the principal port of entry, and one of the capitals of Rhode Island, and the shire town of Providence co., at the head of navigation on an arm of Narragansett bay known as Providence river, 35 m. from the ocean, 43 m. S. S. W. of Boston, and 160 m. N. E. of New York; lat. 41° 49' 22" N., lon. 71° 24' 48" W.; pop. in 1708, 1,446; in 1730, 3,916; in 1774, 4,321; in 1790, 6,380; in 1800, 7,614; in 1820, 11,745; in 1830, 16,836; in 1840, 23,172; in 1850, 41,513; in 1860, 50,666; in 1870, 68,904, of whom 17,177 were foreign born; in 1874, 99,608; in 1875, 100,675. Of the population in 1874, 3,557 were colored, 48,074 males, and 51,534 females; 48,351 were of American and 51,257 of foreign parentage, including 36,990 of Irish, 9,532 of English, Scotch, or Welsh, and 2,212 of German descent. There were 16,038 children between 5 and 15 years of age; 20,934 families, with an average of 4.76 persons to each; and 12,188 dwelling houses, with an average of 8.17 to each. The number of families in 1875 was 21,578; of dwellings, 13,383. In population and wealth Providence is the second city in New England. It formerly covered 5.31 sq. m., but in 1867 3.61 sq. m. were annexed from Cranston, forming the 9th ward, and in 1874 5.84 sq. m. from North Providence, forming the 10th ward; the present area is therefore 14.76 sq. m. The city is bounded E. by the Seekonk river, here crossed by two bridges, and lies on both sides of Providence river, which is crossed by a draw bridge and four fixed span bridges. Above this, and within the centre of the city, the river expands into a beautiful cove nearly a mile in circuit, along which is a wall surmounted by an iron railing. A park planted with elms, with gravelled walks, surrounds the cove. Two small streams enter on the north, the Moos-hassuck and the Woonasquatucket rivers, upon which are many machine shops and manufactories. The land on which the city stands is very irregular. On the E. side a hill rises to the height of 204 ft. above tide water. On the west it is level, with little elevation for a quarter of a mile, when the land rises to the height of 75 ft. The hillsides, even to their summit, are covered with dwelling houses, interspersed with gardens and ornamented with trees. The larger portion of the dwelling houses in the city are of wood; the remainder

are of brick and stone, among which are many mansions of great elegance. Several of the churches present fine specimens of architecture. The arcade, on the W. side, is the finest of the kind in the United States. It extends from Westminster to Weybosset street, 225 ft. in length by 80 in width, a portion in the centre being about 50 ft. wider; it is three stories high, has 78 shops, and is devoted chiefly to the retail trade, the principal articles sold being dry goods, boots and shoes, hats, and jewelry. The building is of granite, with two imposing Doric porticoes, one on each street. In the vicinity is the massive granite building of the custom house and post office. The state house is a brick building on the E. side of Providence river. Several of the school houses are handsome buildings. The new opera house and the Butler exchange are also fine structures. Near the railroad depot the state has erected a monument to its citizens who fell in the civil war; it was completed in 1871 at a cost of \$60,000, and consists of a base of blue Westerly granite, with five bronze statues. In the same vicinity a granite building for the city hall has recently been commenced, which will cost about \$675,000. The present city hall is a three-story brick structure. A county court house is to be erected on the corner of Benefit and College streets. The Narragansett hotel, in course of construction, is to be of stone, brick, and iron, seven stories high, covering 22,000 sq. ft. There are several small public squares. Roger Williams park, containing about 100 acres, is near the W. shore of Narragansett bay, in the S. part of the city; it was devised to the city in 1871 by Betsy Williams, a descendant of Roger Williams. The north burying ground, in the N. part of the city, is the property of the municipality; it contains 122 acres. Swan Point cemetery, on the E. bank of the Seekonk river, embraces a large tract of beautifully diversified land, laid out at a great cost and elegantly ornamented.—The following railroads connect Providence with the principal points in New England: Boston and Providence; Hartford, Providence, and Fishkill; New Bedford; Providence, Nantucket, and Cape Cod; Providence and Springfield; Providence and Stonington; Providence and Worcester; Warwick; Fall River, Warren, and Providence; and Providence, Warren, and Bristol. All of these except the last two occupy the same passenger depot, a spacious and elegant structure of brick nearly 700 ft. long, situated near the heart of the city on the S. side of the cove, and near the great bridge. Horse cars run through different parts of the city and to the adjoining towns. A daily passenger line and a semi-weekly freight line of steamers ply to New York, and steamers also run to Philadelphia, Baltimore, Norfolk, and Charleston, and to Fall River, Newport, and various points on Narragansett bay. During the colonial period Providence enjoyed an extensive foreign

commerce, which has now greatly fallen off, and its commerce is chiefly confined to the coasting trade. The value of foreign commerce for the year ending June 30, 1875, was \$589,545 (\$23,086 exports and \$566,459 imports). The number of arrivals from foreign ports during the same year was 148; of coastwise arrivals, 5,852; number of vessels belonging to the port at the close of the year, 142, tonnage 36,995.—Providence is the leading market for the trade in domestic printing cloths. The sales since 1864 have been as follows:

YEARS.	No. of pieces.	YEARS.	No. of pieces.
1864.....	2,697,150	1870.....	5,540,800
1865.....	4,112,700	1871.....	6,612,800
1866.....	2,953,700	1872.....	4,742,800
1867.....	2,688,000	1873.....	8,888,100
1868.....	4,701,900	1874.....	2,648,210
1869.....	2,175,000		

The pieces average 43 yards each. Its manufactures are very extensive, and include cotton and woollen goods, iron, gold, and silver wares, and numerous other articles. The American screw company possesses five large mills and five storehouses, besides other buildings; the mills have a capacity for the employment of about 2,500 hands, and for the production daily of nearly 40,000 gross of wood screws, several tons of rivets, large quantities of machine screws, stove bolts, coach screws, tire bolts, &c. The Providence tool company produces heavy and ship chandlers' hardware, sewing machines, and the Peabody breech-loading rifle; the works cover more than five acres and employ 1,500 hands. The Providence steam engine company manufactures the Greene cut-off engine, and also steam boilers and riveting machines. The works of the Barstow stove company cover more than two acres. The Allen fire department supply company manufactures steam fire engines, fire hose, hose carriages, hose couplings, discharge pipes, hydrants, fire escapes, &c.; it has a brass foundry in connection with its works, in which brass finishing is extensively carried on. The manufacture of gold jewelry is the most prominent industry of the city; more than 150 establishments of all sizes are engaged in it, and the annual product is about \$5,000,000. The Gorham company's manufactory of solid silver ware employs nearly 400 hands, and is the leading silver manufactory of the world. There are several establishments for the refining of gold and silver, in which are smelted large quantities of sweepings and refuse obtained from the jewelry establishments. About 25 establishments are engaged in the manufacture of woollen cloths, yarns, &c., and worsted goods; and about 50, with 150,000 spindles, in the manufacture of printing cloths, yarns, battings, thread, spool cotton, lacings, braids, and other cotton goods. The Fletcher manufacturing company employs 500 hands, and is the largest

establishment in the country, and probably in the world, engaged in the manufacture of "small wares," comprising boot, shoe, and corset lacings, lamp wicks, yarns, braids, &c.; the buildings cover four acres. There are three large cloth-printing establishments, and several shops for the engraving of copper rollers for printing calicoes. Among other establishments, the Rumford chemical works (in East Providence), the manufactory of Perry Davis's "pain killer," the Corliss steam engine works, the stove works of Spicers and Peckham, and the Rhode Island locomotive works are noteworthy. There are also several bleaching and calendering establishments, and manufactories of alarm tills, toilet and laundry soaps, ribbons, &c. Providence contains 23 national and 12 state banks, with an aggregate capital of \$17,707,850; 10 savings banks, with deposits to the amount of \$25,807,905; 1 trust company, capital \$500,000; 1 safe deposit company, capital \$50,000; and 20 insurance companies, with assets to the amount of \$13,175,629.—The city is divided into 10 wards, and is governed by a mayor, a board of aldermen of 10, and a common council of 40 members, elected annually. The mayor, aldermen, and common council in their joint capacity are styled the city council. At the close of 1874 the police force numbered 190 men. The number of arrests during that year was 8,440, of which 4,950 were for drunkenness. There is an effective paid fire department, consisting of 146 officers and men organized into five steam engine companies, six hose companies, and three hook and ladder companies. The city is supplied with water from the Pawtuxet river, 6 m. distant, by works recently constructed at a cost of about \$4,250,000. Since 1855 much attention has been given to vital statistics in Providence, and the returns of births, marriages, and deaths are probably more complete and perfect than those of any other city in America. During the same time special efforts have been made for the prevention of disease. In addition to this there are some peculiarities of natural location and internal construction which make the city very healthy. During the year 1873, with a population of 80,592, there were 1,719 deaths, 1,150 marriages, and 2,128 births; or one birth in 37·83, one person married in 35·04, and one death in 46·88 of the population. The annual average for 19 years, 1855 to 1873 inclusive, was one birth in 34·19, one person married in 38·10, and one death in 50·65 of the population. The valuation of real estate in 1874 was \$81,040,300; personal estate, \$42,642,500; total, \$123,682,800; rate of tax, \$14 50 per \$1,000; amount of tax, \$1,793,400 60. The receipts into the city treasury during the year ending Sept. 30, 1874, including a balance on hand of \$177,159 67, were \$7,968,233 36, of which \$1,520,716 68 was from taxation, \$5,722,289 52 from loans, and \$184,574 90 from water works. The expenditures were \$7,505,-

590, of which \$6,158,354 05 were classed as extraordinary and \$1,347,235 95 as ordinary; balance in treasury Sept. 30, 1874, \$462,643 36. The funded debt on Sept. 30, 1874, was \$5,400,000; floating debt, \$2,043,800; total, \$7,443,800. Deducting \$1,493,748 64 assets available for its reduction, the net debt was \$5,950,051 36.—Providence has many charitable institutions and associations. The Butler hospital for the insane, founded in 1847, is on the W. bank of Seekonk river, surrounded by extensive grounds, 60 acres of which are under cultivation, with about the same extent of native woodland. The average number of patients is about 130. The edifice was erected and the lands purchased by subscription, Cyrus Butler contributing \$40,000, and Nicholas Brown \$30,000. Its annual net disbursements are about \$55,000. The state of Rhode Island makes an annual appropriation of \$2,000 to enable the governor to aid poor insane persons there, and it also pays a portion of the expenses of all such poor insane as the town may choose to send. The Dexter asylum for the poor is situated on high land E. of the river. It is a fine edifice of brick, 170 ft. long, including wings, and three stories high. The grounds, which comprise about 40 acres, are enclosed with a stone wall 8 ft. high. The land was devised by Ebenezer Knight Dexter in 1824, and the buildings erected by the city in 1828. The Rhode Island hospital, founded in 1863, has stately buildings surrounded by pleasant grounds, in the S. part of the city, fronting on the harbor. Other important institutions are two homes for the aged, the nursery, a Roman Catholic orphan asylum, and two dispensaries. The reform school, established in 1850, for juvenile offenders between the ages of 8 and 18, is in the S. W. part of the city. The number of inmates at its last annual report, 1874, was 220, of whom 179 were boys and 41 girls. Its expenses for the year were \$40,753; earnings, \$13,222. The state prison is on the N. side of the cove. At the close of the year 1874 it contained 67 convicts. The county jail is within the prison walls. The convicts are almost exclusively employed in cabinet work and shoemaking.—The following are the statistics of public schools for 1873-'4:

SCHOOLS.	No. of schools.	No. of rooms.	Whole number of teachers.	No. of male teachers.	No. of female teachers.	No. of pupils.
High school.	1	9	12	4	8	393
Grammar schools.	7	60	68	7	61	2,687
Intermediate.	26	50	55	..	55	2,128
Primary....	29	64	86	..	86	8,962
Evening....	7	13	87	37	50	2,074
Vacation....	6	6	17	..	17	1,200
Total.....	76	202	325	48	277	12,439

There were also seven special teachers. The expenditure for school purposes in 1873 was \$267,597 25, viz.: salaries, \$146,656 13; houses and lots, \$91,738 97; incidental expenses, \$29,202 15. The schools are under the immediate

supervision of a superintendent, but the general control is vested in a school committee, consisting of the mayor and president of the common council *ex officio* and six members from each ward, whose term of office is three years. The Friends' yearly meeting boarding school, or "Quaker college," occupies a lot of 43 acres in the E. part of the city. It consists of two spacious brick buildings, three stories high with wings of two stories. It is liberally endowed and in a prosperous condition. A legacy of \$100,000 was bequeathed to it by the late Obadiah Brown. It was established in 1819, and is under the direction of a committee of the New England yearly meeting. The Roman Catholics have three flourishing academies, one male and two female. The grounds and buildings of Brown university occupy an elevated situation in the E. part of the city. (See BROWN UNIVERSITY.) The Athenæum, incorporated in 1836, is a handsome granite building, containing a reading room and a well selected library of 34,000 volumes, to which large additions are annually made. The Rhode Island historical society, founded in 1822, occupies a fine brick and granite building opposite the university grounds, erected in 1844, and containing a library of 6,000 volumes and 35,000 pamphlets, besides a large collection of manuscripts and other memorials relating to the history of the state. The Franklin society, incorporated in 1823, has for its object the cultivation and dissemination of a knowledge of the natural sciences and the mechanic arts. The Franklin lyceum has a reading room and a library of 8,000 volumes. The mechanics' and apprentices' library numbers 6,500 volumes, and that of the young men's Christian association 5,000. Steps have been taken toward the establishment of a free public library. Four daily, one semi-weekly, and five weekly newspapers, and three monthly periodicals are published. There are 76 churches, viz.: 13 Baptist, 2 Christian, 7 Congregational, 12 Episcopal, 1 Evangelical Lutheran, 5 Free Baptist, 1 Friends', 2 Jewish, 10 Methodist Episcopal, 1 Presbyterian, 10 Roman Catholic, 1 Swedenborgian, 3 Unitarian, 1 United Presbyterian, 2 Universalist, and 5 miscellaneous. The first Baptist church, the oldest in America, was founded here in 1638.—Providence was first settled in 1636 by Roger Williams, who was banished from Massachusetts on account of his religious opinions, and who, in his new colony, was the first to propose and establish the principles of universal freedom in religious matters. The rock on the banks of the Seekonk river on which he landed, and where he was received by the Indians, is about a mile from the centre of the city. The town received its first patent from Charles I., bearing date 1643. It suffered much in the famous war of King Philip, in 1675, when a considerable portion of it was burned. It again suffered severely in September, 1815, when a southeasterly storm forced an extra-

ordinary tide into the harbor, raising the water 12 ft. higher than the usual spring tides, spreading devastation and ruin along the wharves and the lower part of the town, overturning houses and stores, and doing much damage to the shipping. One large East Indiaman was driven up beyond the cove, and never removed. Providence received a city charter in 1832. The first printing press was established here by William Goddard in 1762, from whose office the "Providence Gazette" was issued.

PROVIDENCE, Sisters of. See SISTERHOODS.

PROVINCETOWN, a town of Barnstable co., Massachusetts, occupying the extremity of Cape Cod, at the terminus of the Cape Cod division of the Old Colony railroad, 120 m. by rail and 55 m. by water S. E. of Boston; pop. in 1850, 3,157; in 1860, 3,206; in 1870, 3,865. The town is 4 m. long by 3 m. in width at the widest part. The harbor is on the inner side of the cape, and is almost entirely landlocked. It is unsurpassed for size and depth of water, covering an area of 3 by 5 m., 30 fathoms deep in the deepest parts, without rocks, bars, or shoals. The village skirts the shore of the harbor, and is formed of wooden buildings, compactly built, presenting a beautiful view from the water. Provincetown is a popular summer resort. It is noted for its cod, mackerel, and whale fisheries. In 1875 there were owned here 185 vessels, with an aggregate tonnage of 16,000, of which 20 were employed in coasting, 19 in whaling, and 146 in the cod and mackerel fisheries. The average annual catch of codfish for the four years ending in 1875 was 80,000 quintals; of mackerel, 20,000 barrels. In whaling the town ranks with New London next to New Bedford. It contains three marine railways, 30 wharves, a national bank with a capital of \$200,000, a savings bank with deposits amounting to \$500,000, and three marine insurance companies with an aggregate capital of \$250,000. It has a fine fire department. The assessed value of property in 1875 was about \$2,000,000. There are 14 public schools (1 high, 1 grammar, and 12 intermediate and primary), supported at an annual cost of \$7,400, exclusive of repairs of building; a weekly newspaper; a public library of 2,200 volumes; and six religious societies.—In Provincetown harbor the Mayflower first cast anchor in America. Here the pilgrims signed the first compact of government, and here the first child in New England of English parentage was born.

PROVOOST, Samuel, an American bishop, born in New York, March 11, 1742, died Sept. 6, 1815. He graduated at King's (now Columbia) college in 1758, and in 1761 entered as fellow commoner of St. Peter's college, Cambridge, England. He was ordained in 1766, returned to New York, and was assistant minister of Trinity church till 1768. In 1770 he retired to a small farm in Dutchess co., remained there till the close of the revolution, and was then elected rector of Trinity church. He was chap-

lain to the continental congress in 1785, and to the senate of the United States in 1789. Having been elected bishop of New York in June, 1786, he accompanied Dr. William White to England, and was consecrated with him, Feb. 4, 1787, at Lambeth palace. In 1800, on account of his health, he resigned the rectorship of Trinity church, and in 1801 the episcopal office. The latter resignation was not accepted by the house of bishops, and Dr. Benjamin Moore was chosen his coadjutor.

PROVOST, Jean Baptiste François, a French actor, born Jan. 29, 1798, died Dec. 24, 1865. He studied at the conservatory in Paris, and became professor of elocution in 1839. He played at the Odéon theatre from 1819 to 1828, and at that of Porte Saint Martin till 1835, when he appeared at the Théâtre Français, of which he became a member in 1839. His most celebrated rôles as a tragedian were Claude in *Valérie* (1852), the marquis de Rieux in *Duc Job* (1858), the banker Charrier in Augier's *Effrontés*, and the deputy marshal in the same author's *Le fils de Giboyer* (1863-'4).

PRUDENTIUS, Aurelius Clemens, a Latin poet, born in Spain in A. D. 348, died early in the 5th century. He was a lawyer, became a civil and criminal judge, and was appointed to a high military station at court. In his later years he devoted himself to religious exercises and study. His extant poems are: *Præfatio*, giving a catalogue of his works up to his 57th year, with a brief autobiography; *Cathemerinon Liber*, 12 sacred hymns, some of which have been inserted in the liturgy of the Roman Catholic church; *Apotheosis*, maintaining the divinity of Christ and the doctrine of the Trinity; *Hamartigenia*, on the origin of sin, directed against the Marcionites; *Psychomachia*, representing the struggle between virtue and vice in the soul, and the triumph of the former; *Contra Symmachum Liber I.*, an account of the conversion of Rome, with an exposure of the folly of the ancient religion; *Contra Symmachum Liber II.*, a refutation of the argument of Symmachus in his petition to the emperor Valentinian; *Peri Stephanon Liber*, 14 poems in honor of martyred saints; *Diptychon* or *Dittochaon*, 48 poems in heroic hexameters, 24 describing events and characters in the Old Testament, and 24 in the New, about the authenticity of which there has been much controversy; and the *Epilogus*. The earliest dated edition of his works is that of Deventer (1472); the best is that of Faustus Arevalus (2 vols. 4to, Rome, 1788-'9). His works are also published in vols. lix. and lx. of Migne's *Patrologie latine*.—See Bayle, *Cathemerinon, traduit et annoté, avec une étude sur Prudence* (8vo, Paris, 1860).

PRUD'HON, Pierre Paul, a French painter, born at Cluny, April 4, 1758, died in Paris, Feb. 16, 1823. He was educated by charity, developed a taste for art, and was placed under the tuition of Devosges at Dijon. Having won a prize awarded by the states of Burgundy, he

went to Rome, where he became intimate with Canova. In 1789 he went to Paris, where he supported himself by painting miniatures and making drawings for concert tickets, bill heads, tradesmen's cards, and confectionery boxes. In 1794 he went to Rigney, near Gray, and executed a series of pastel portraits for which he received a handsome price. On his return to Paris he won a prize for an allegorical drawing, representing "Wisdom and Virtue descending upon earth." In 1805 he painted on a ceiling in the museum of the Louvre "Diana imploring Jupiter;" and in 1808, for the hall of the criminal court, "Justice and Divine Vengeance pursuing Crime." For this he received from Napoleon the cross of the legion of honor, was appointed teacher to the empress Maria Louisa, and became a member of the institute. He painted "Psyche borne away by the Zephyrs" (1808), "Zephyr balancing himself upon the Water," a portrait of the king of Rome, "Venus and Adonis" (1810), "Andromache" (1817), and "The Assumption" (1819). In 1821 his pupil Constance Mayer, for whom he entertained a warm affection, put an end to her life, and thenceforth he pined away. He nevertheless completed "The Indigent Family," the rough draught of which had been left by his unfortunate pupil, and "Christ dying upon the Cross," which was exhibited after his death.

PRUNE. See **PLUM**.

PRUNING, a most important horticultural operation, which consists in removing a portion of a plant for the benefit of that which remains. The operation may be required by all plants which have an above-ground stem, even the most delicate. It is performed either to induce a vigorous growth, or to diminish vigor and dwarf a plant; a tree which does not bear is pruned to increase its fruitfulness, or it may be pruned to prevent over production. It requires to be done understandingly; and so much injury has resulted from indiscriminate pruning, that certain cultivators go to an opposite extreme, and advise not to prune at all. Where trees grow in a dense forest we find tall straight trunks without a branch for 50 ft. or more, and at the top a small branching head, that in size is quite out of proportion to the trunk; when such trees are felled and sawed into boards, we see by the knots that a natural pruning has been carried on for years; the lower branches of the trees were so excluded from the light by the growing tops that they were smothered and fell away, while the wounds were closed so neatly that no external indication of their presence is manifest. Trees of the same species with those which grow in the forest, when found as isolated specimens, are much shorter, but clothed with branches from the base upward. In this country pruning has until recently been regarded as belonging only to fruit trees, but in those parts of Europe where forestry is a distinct art, forest trees are pruned with a view to their

future uses for timber, and while some are made to grow with a clear straight trunk, in other cases their branches are encouraged and so directed as to form knees required in ship building. In this country pruning is most fre-

FIG. 1.—A Young Tree Pruned and Unpruned.

quently done upon old orchards, in which the trees have been left to themselves since they were first planted, and are unfruitful except on the extreme outer twigs on account of the crowded condition of their heads, in which branches cross one another in a confused mass, impenetrable to light and air. In such cases all that need be done is to remove the superfluous wood in such a manner as to leave an evenly balanced and open head. The intelligent fruit grower will prefer to set trees only one year old from the bud or graft, and they will be either simple wands or stems, furnished with buds along their length, or a few of the upper buds may have pushed and formed branches; with a tree like this to start with, he can form the head at such height as best

FIG. 2.—Right and Wrong in Pruning.

til those at its lower part, being robbed of all nourishment by the rapidly growing shoots above, will not start at all. Such a branch or tree as this may be cut back so that the lower buds only will start and produce shoots, which

will ripen into three or four branches, and these will be strong, from having all the nutriment that would have been divided among numerous shoots were it left unpruned. Similarly the ramification, and consequently the whole head of the tree, may be directed and controlled at will. The effects of judicious pruning upon young trees are strikingly shown in apple and pear trees, which at the end of four or five years of systematic pruning are complete pyramids, with the base near the ground, and the branches equally distributed and gradually diminishing in size to the top.—Pruning is frequently resorted to when trees have become stunted and almost ceased to grow; if the top of such a tree has its branches judiciously cut back, the remaining buds, having to themselves the sap which was formerly divided among the whole, will produce vigorous new shoots, and this will be responded to by a new growth of roots, and the whole tree will be invigorated. These instances have reference to the wood growth of the tree; whatever favors that diminishes the production of fruit, and *vice versa*; hence the pruning to induce fruit-bearing is quite different from that to promote vigor of growth. If a tree is severely pruned soon after its leaves are developed, it receives a sudden check, and it is the tendency of all such shocks to induce the tree to propagate itself by seed; instead of preparing for an extended growth of branches the next year, many of the buds, which would otherwise have produced leafy shoots, become fruit buds. In practice, pruning to produce fruit is not done in this severe manner, but by stopping the extension of a portion of the shoots after they have made a certain growth; as this is done when the shoots are so tender as not to require a knife, it is termed pinching. By careful management the form and fruitfulness of trees may be controlled with but little use of the knife; buds which would produce branches where they are not wanted are broken off soon after they start to grow, and by checking the prolongation of other branches at the proper point an equal distribution of sap, and consequently of growth, is maintained over the whole tree.—Root pruning, or removing a portion of the roots, is resorted to for the purpose of controlling the size of the tree, to produce fruit-

FIG. 3.—A Pyramidal Tree, produced by proper Pruning.

fulness, and to allow the tree to be transplanted. Some trees, especially forest and ornamental ones, produce long roots with very few fine fibrous rootlets, and are difficult to remove unless prepared a year beforehand; the long roots being cut off within a moderate distance of the trunk, the shortened roots will form numerous rootlets, and at the end of a season may be transplanted with safety. Root pruning is one of the readiest methods of checking the too vigorous wood growth of trees and throwing them into bearing; it consists in opening a circular trench around the tree, at a distance governed by the kind and the vigor of the individual, and cutting off with a sharp spade all roots which extend outside of this circle; sometimes half the roots are operated on one year and the other half the next.—The proper time for pruning trees has been the subject of much discussion; wounds heal over most rapidly if made after the season's increase in length is completed, and the fully developed leaves are engaged in maturing the buds and preparing for the growth of another year. This time, since it occurs in summer, is usually an inconvenient one, and the end of winter or very early spring, before vegetation starts, is the season generally selected; this has reference to the removal of branches. Summer pruning, or pinching, is done at the time when its objects can be best accomplished. Whenever it may be performed, the utility of pruning will depend upon the intelligence of the operator, who should understand the laws of plant growth and the peculiar habit of each tree. The peach, for example, produces its flowers and fruit along the branches which grew the preceding year, and is generally much benefited by having these branches shortened in, or cut back, for one third or more of their length; the horse chestnut, on the other hand, produces its flowers and fruit from buds at the ends of branches of the previous year, and if the cutting back so useful to the peach were practised on this, all the flowers would be destroyed. In some plants, like the grape, there are several different methods of pruning to obtain the same result. With the grape, pruning is so intimately related to training that it is difficult to treat of the two separately, and this is especially the case with fruit trees grown upon walls and trellises, whether as espaliers or by the cordon method. In this country the climate does not require the highly artificial methods of training, and the pruning to effect them, so common in Europe; these are given in various English and French works upon fruit culture, and with special completeness in Du Breuil's *Cours élémentaire d'arboriculture*.—As a mechanical operation, pruning requires some skill and care; large cutting is done with a saw made for the purpose, the teeth of which are set wide. An axe should never be used. The wound made by the saw should be smoothed with a drawing knife or other tool, and

covered with shellac varnish, melted grafting wax, or thick common paint, to prevent decay before a new deposit of wood and bark covers it. Every branch should be cut close to the trunk, or other branch to which it is attached; if a stub, or projection of a few inches, be left, this will not heal over, but in time decay will set in, which may extend to the whole interior of the tree. The decay of many orchards may be traced to this fault in pruning. For the removal of branches two inches in diameter or less, a heavy chisel made for the purpose, and driven from below upward with a mallet, makes quick and neat work. A heavy knife is used for the removal of twigs, and for shortening young growths; shears made for the work do it quicker, but do not leave so clean a cut as the knife, though in many cases they answer. In shortening a twig or small branch, the cut should be made at a bud, and as the shoot from this will continue the upward growth of the branch, it is of some importance to cut to a bud pointing in the desired direction, as the future shape of the tree will be materially influenced by it. Cutting must not be done too far above a bud, as this will leave a stub which, having no leaves to sustain it, will die down to the bud; if the cut is made too close to the base of the bud, there is danger that it will dry out or be otherwise injured; the proper cut is made by placing the knife at a point opposite the base of the bud, and bringing it out, with a slightly upward slanting cut, opposite the apex of the bud.

PRUSA, or Prusias. See BRUSA.

PRUSSIA, the largest and leading state of the German empire, occupying a northern central portion of the European continent, between lat. 49° and 56° N., and lon. 5° 45' and 23° E. It is bounded N. by the North sea, Denmark, and the Baltic; E. by Russia; S. by Cisleithan Austria, the kingdom of Saxony, the Thuringian states, Bavaria, Hesse, and Alsace-Lorraine; and W. by Luxemburg, Belgium, and Holland. Its greatest length, from a point near where the Niemen or Memel crosses the N. E. frontier to the point of junction of its boundaries with those of Luxemburg and Alsace-Lorraine, is 800 m.; the longest line that can be drawn on its soil in a direction nearly at right angles to this extends from the Baltic coast N. W. of Stralsund to the S. E. extremity of the province of Silesia, and measures a little more than 400 m. The area of Prussia, according to the official figures which are made the basis for the land tax (but which, owing to very recent territorial changes, are perhaps not absolutely accurate), is 136,656 sq. m. including the area of all the principal gulfs, bays, and arms of the sea, and 134,496 sq. m. excluding all bodies of water except inland lakes. The kingdom is divided into 12 provinces (inclusive of the detached Hohenzollern, and exclusive of Lauenburg), and these into administrative districts named after their respective chief towns, as follows:

PROVINCES.	Area, sq. miles.	DISTRICTS.
Prussia.....	24,114	Königsberg, Gumbinnen, Dantzic, Marienwerder.
Brandenburg.....	15,403	(Berlin), Potsdam, Frank- fort-on-the-Oder.
Pomerania.....	11,630	Stettin, Köslin, Stralsund.
Posen.....	11,179	Posen, Bromberg.
Silesia.....	15,556	Breslau, Liegnitz, Oppeln.
Saxony.....	9,746	Magdeburg, Merseburg, Er- furt.
Schleswig-Holstein.....	6,766	Schleswig.
Hanover.....	14,856	Hanover, Hildesheim, Lüne- burg, Stade, Osnabrück, Aurich.
Westphalia.....	7,799	Münster, Minden, Arnberg.
Hesse-Nassau.....	6,138	Cassel, Wiesbaden.
The Rhine Province.....	10,416	Coblenz, Düsseldorf, Co- logne, Treves, Aix-la-Cha- pelle.
Hohenzollern.....	440	Sigmaringen.
Total.....	134,043	
Duchy of Lauenburg.....	453	
Grand total.....	134,496	

Until 1866 the territory of Prussia was not only divided into two portions by the kingdom of Hanover, the electorate of Hesse, and other foreign possessions lying in its midst, but was also dotted here and there by small independent principalities and duchies, which greatly hindered its unity of action and made its political geography extremely complicated. These have all been absorbed since the war of 1866, with the exception of the following small states and tracts of land, which are still subject to other German powers, though surrounded by Prussian territory: three communes in the province of Brandenburg, belonging to Mecklenburg-Schwerin; the city of Hamburg and vicinity, with tracts belonging to it in Holstein and Hanover; the duchy of Anhalt, divided into eight portions; the duchy of Brunswick, also in eight portions; the principalities of Schaumburg-Lippe (in two portions) and Lippe-Detmold; the principality of Waldeck (in two portions); Allstedt and Oldisleben, a territory belonging to Weimar (in two portions); Volkerode, belonging to Gotha; territories belonging to Schwarzburg-Sondershausen and Schwarzburg-Rudolstein; the village of Mumsdorf, belonging to Altenburg; the Hessian province of Upper Hesse, with a territory belonging to it in the province of Hesse-Nassau; the principality of Birkenfeld in the Rhine province, belonging to Oldenburg; two tracts owned by Baden and three by Würtemberg in the Hohenzollern domains. The larger territory of the duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz (with the adjoining Lübeck and a detached portion of Oldenburg) in the north, and the grand duchy of Oldenburg (with the adjoining Bremen) in the northwest, each surrounded by Prussian territory on three sides, but having their own seacoast, are now the only states of consequence which break in upon the outline and territorial unity of the country.

In addition to the united territory enclosed by the boundaries given above, Prussia has the following outlying possessions: six communes and domains in Mecklenburg-Schwerin; Grossmenow in Mecklenburg-Strelitz; a commune, formerly belonging to Hanover, in the territory of Hamburg; seven communes in Anhalt; four tracts in Brunswick; one in Oldenburg; the town of Lügde between Lippe-Detmold and Waldeck; two villages in Waldeck; Kischlitz in Saxe-Altenburg; the circle of Ziegenrück, in six portions, lying near Meiningen, Weimar, Rudolstadt, &c.; Moleschütz, Abtlöbnitz, and Barchfeld in Saxe-Meiningen; Wandersleben and Mühlberg in Saxe-Gotha; the circles of Schleusingen and Smalcald in Thuringia, in several divisions; and the domains of the Hohenzollerns, in eleven portions, scattered through the territory of Baden, Würtemberg, and Bavaria. The duchy of Lauenburg belongs to the king of Prussia, without being consolidated with the kingdom. (See LAUENBURG.)—The coast line of Prussia on the North sea is about 250 m. long; on the Baltic it measures about 750 m. On both seas the shore is almost uniformly flat and low; so much so that at several points on the North sea, and where the province of Prussia borders on the Baltic, dikes have been built to protect the tracts of nearly level land that stretch away from the water's edge, parts of them lying lower than the surface of the ocean. The only exceptions to this formation are the more rugged coasts of N. E. Schleswig, and the high chalk cliffs of the island of Rügen, lying in the Baltic off Stralsund. On the North sea the Dollart (the estuary of the Ems), the bay of Jade, and the estuaries of the Weser and Elbe, form excellent harbors, their ports being respectively Emden, Wilhelmshaven, Bremen, and Hamburg; while on the Baltic the best are those of Kiel, Stralsund, Stettin, and Dantzic, the last two respectively at the mouths of the Oder and Vistula. The chief gulfs and bays are formed on both seas by the broadening estuaries of the rivers named, the Oder and Vistula forming at their mouths large bodies of water almost enclosed by land, known respectively as the Stettiner Haff and the Frisches Haff, while the Kurisches Haff, at the extreme N. E. of the coast, is a similar body receiving the river Memel.—The greater part of the surface of Prussia is flat and low; an extended plain, sloping toward the north, and only broken by small detached ranges of hills, forms the northern portion. The direction of such ranges is in almost every case N. E. and S. W.; but the highest of their summits in the north is the Thurmberg, near Dantzic, 1,131 ft. The surface of the S. part is more varied, and some portions of it are mountainous and picturesque. The S. W. boundary of Silesia is formed by the Riesengebirge (highest peak about 5,300 ft.) and its various continuations. The N. and E. parts of the province of Saxony form almost a perfect level, interrupted only

by inconsiderable hills; the S. W. portion is intersected by projecting spurs of the Hartz mountains (highest elevation the Brocken or Blocksberg, 3,737 ft.), and the Thuringian forest. Westphalia, the Rhine province, and Hesse-Nassau contain the N. W. group of the mountain system of Germany, each of its numerous ridges having its own distinctive name. The more important are: on the right bank of the Rhine, the Taunus, the Weser hills, including the picturesque gap known as the Porta Westphalica, the Tentoburg forest (the battle ground of the Germans and Romans), the Rothhaar hills, the Sauerland hills (2,800 ft.), the Siebengebirge, the Westerwald, the Spessart, the Rhön, and offshoots from the Vogelsberg; on the left bank of the Rhine, the Hunsrück, Hohe Venn, and Eifel (2,500 ft.). The Hohenzollern territory is intersected by the Raue Alp.—Prussia contains a large number of lakes, especially in the level N. E. section, but none of them are of much importance. (For the principal lakes see GERMANY, vol. vii., p. 746.) There are large swamps on the lower course of the Havel, Oder, Warthe, and Netze rivers, which many attempts have been made to drain. All the river systems of Prussia belong to the basins of the Baltic and North seas. The principal rivers belonging to the basin of the Baltic are the Memel, Vistula (with its tributaries the Drewenz and Brahe), and Oder (with its tributaries the Bartsch, Bober, Neisse, and Warthe). Independent of these are a number of coast rivers, viz., the Dange, Pregel, Passarge, Elbing, Leba, Lupow, Stolpe, Wipper, Persante, Rega, Ihna, Peene, Ucker, Recknitz, and Trave, nearly all of them navigable for some distance. Belonging to the North sea basin are the Eider, the Elbe (with its tributaries the Mulde, Saale, and Havel), the Weser, formed by the Werra and Fulda (with its tributary the Aller), the Ems (with the Vechte), and the Rhine. The Rhine flows through Prussian territory about 200 m., entering it at Mentz, forming about 29 m. of the boundary of Hesse-Darmstadt, receiving on the right bank the Main, Lahn, Wied, Sieg, Wipper, Ruhr, and Lippe, and on the left bank the Nahe, Moselle, and Ahr, and passing into Holland a little below Emmerich. Prussia has a large number of artificial watercourses, the Vistula and Oder being connected by the Bromberg canal, the Oder and Spree (an affluent of the Havel) by the Müllrose canal, the Havel and Elbe by the Plau canal, the Elbe and Trave by the Stecknitz canal, and the Eider and the Baltic by the Eider canal. Other canals connect small adjacent river systems in the western provinces.—The climate is wholesome and temperate. The mean temperature at Königsberg is 43° F., at Berlin 48°, at Aix-la-Chapelle 49°, and at Cologne and Treves 50°. The soil, though in some mountainous districts of the western section extremely desolate and sterile, and in a large division of the middle provinces a poor loamy sand, is on the whole

fertile, and preëminently so in the bottoms of the Elbe, Saale, Unstrut (an affluent of the Saale), Oder, Warthe, Netze, and some other rivers. Even where it is naturally poor, a well developed system of agriculture, assiduously fostered by the government, renders it highly productive.—The population of Prussia, according to the census of 1871 (corrected tables of 1873), was as follows:

Prussia.....	8,137,545
Brandenburg.....	2,863,229
Pomerania.....	1,481,638
Posen.....	1,583,843
Silesia.....	3,707,167
Saxony.....	2,103,174
Schleswig-Holstein.....	995,873
Hanover (including the Jade district).....	1,963,618
Westphalia.....	1,775,175
Hesse-Nassau.....	1,400,370
Rhine Province.....	8,579,347
Hohenzollern.....	65,558
Soldiers and sailors not included above.....	37,409
Total.....	24,643,951
Duchy of Lauenburg.....	49,546
Grand total.....	24,693,497

The excess of females over males was 357,542. Of the entire population about 21,800,000 speak German, 146,800 are Lithuanians, 2,420,000 (in Prussia, Posen, and Pomerania) Poles, 50,000 (in Silesia) Czechs, 83,000 (in Silesia and Brandenburg) Wends, 10,400 (in the Rhine province) Walloons, and 145,000 (in Schleswig-Holstein) Danes. Prussia has one city (Berlin) of more than 900,000 inhabitants (in August, 1873, 909,580), 5 of from 100,000 to 210,000 (Breslau, Cologne, Magdeburg, Königsberg, and Hanover), 12 of from 50,000 to 100,000 (Frankfort-on-the-Main, Dantzic, Stettin, Barmen, Elberfeld, Aix-la-Chapelle, Altona, Düsseldorf, Crefeld, Posen, Halle, and Essen), and 6 of from 40,000 to 50,000 (Cassel, Dortmund, Potsdam, Erfurt, Frankfort-on-the-Oder, and Gölitz). The number of births in 1872 was 1,023,005, of which 73,527 were illegitimate and 40,505 still-born; of deaths, 765,360; of marriages, 255,421. The number of emigrants from 1844 to 1872 was 706,562; of immigrants, 110,973.—Of the total area of the kingdom, 50·1 per cent. consists of tilled fields, gardens, vineyards, and orchards, 18·3 meadows, 23·1 woodland, and 8·5 unproductive land. All kinds of grain are produced in abundance in Prussia proper, Posen, Silesia, and Saxony, all of which export breadstuffs to the other provinces or to foreign countries. An average grain crop is estimated at 53,000,000 bushels of wheat, 194,000,000 of rye, 34,000,000 of barley, and 154,000,000 of oats. Of potatoes about 495,000,000 bushels are raised. Spelt, peas, rape seed, dyestuffs, herbs, flax, hemp, chicory, hops, and beets (chiefly used for the sugar manufacture) are cultivated in large quantities in all parts of the kingdom. Tobacco is largely raised in western and central Prussia, but has of late considerably decreased in amount; the produce of raw tobacco in 1869 was about 17,000,000 lbs. Of the vineyards full four fifths are on the Rhine and its tribu-

taries; their average yield is about 10,000,000 gallons. Wine of good quality is produced only near the Rhine; those brands which are produced in Saxony (Naumburg) and Silesia (Grüneberg) are proverbially bad. The forests furnish an abundance of excellent timber and lumber. In the raising of domestic animals the progress of Prussia since its reconstruction after the wars of Napoleon has been more marked than in any other agricultural pursuit. The breed of horses has been so improved by government studs, that not only are all the horses wanted for army purposes obtained within the state, but large numbers are exported to neighboring countries. In 1873 the total number of horses was 2,278,274, of cattle 8,612,150, of sheep 19,624,758, and of swine 4,278,531. Hogs are most numerous in Westphalia, geese in Pomerania, bees in Brandenburg and Westphalia, and goats in the mountainous districts; poultry is abundant everywhere. The fisheries on the shores of the Baltic and on the lakes and rivers are important, and all kinds of game common to central Europe are found in the forests. Wolves are seen only in Prussia proper and Posen, where also a few specimens of the aurochs and elk are carefully preserved. The lynx, fox, badger, marten, beaver, otter, and wild fowl are met with in different parts of the kingdom. Seals are sometimes caught in the Baltic.—Mining industry advanced with astonishing rapidity within the second quarter of the present century; it received a temporary check in 1858, but has since made great progress, especially in the production of coal, iron, and zinc. In 1872 the total number of mines in Prussia was 2,702, among which were 476 coal mines, 544 of brown coal, 1,559 of iron, 130 of lead, 82 of zinc, 39 of copper, 5 of vitriol, 46 of manganese, and 1 of cobalt, employing 225,936 hands, including women and children. The total value of mining products was \$82,460,000. The production of coal in 1872 amounted to 581,000,000 cwt., that of brown coal to 146,000,000 cwt. In the production of raw iron Prussia exceeds all other states of the European continent; in the production of zinc all the countries of the world. The value of the products of furnaces, founderies, puddling works, &c., in 1872, was \$59,000,000. About 9,280,000 cwt. of salt was produced in that year. A very small quantity of gold is found; and agate, amethysts, alabaster, marble, gypsum, clays, &c., are obtained. Amber is found on the Baltic coast. Among the mineral springs of Prussia the following enjoy the widest reputation: Warmbrunn, Salzbrunn, Reinerz, and Landeck in Silesia; Freienwalde in Brandenburg; Lauchstädt in Saxony; Driburg in Westphalia; the sulphur springs of Aix-la-Chapelle; Wiesbaden, Ems, Selters, Schwalbach, and Homburg in Hesse-Nassau.—Up to the beginning of the present century Prussia was mainly an agricultural and military state. Even the efforts of Frederick the Great to

introduce new branches of manufacture were in the main unsuccessful. It was only after the final abolition of serfdom (Oct. 9, 1807), the introduction of municipal self-government (Nov. 19, 1808), and the removal of the mediæval institution of trade guilds (Oct. 28, 1810), that manufacturing industry began to take root in Prussia. Soon after Napoleon's downfall the government turned its earnest attention to fostering home manufactures, and during the past 50 years the industry of Prussia has steadily and rapidly advanced. In 1806 the population of Prussia was 10,000,000, with an average income of \$10 to each inhabitant; the capital invested in manufacturing establishments little exceeded \$200,000,000, and the number of free laborers was 480,000. In 1856 the average income of over 17,000,000 inhabitants was \$42 each, the capital invested in manufactures \$770,000,000, and the number of free laborers 2,771,000. In 1872 the total income of the 24,600,000 inhabitants was estimated at \$1,880,000,000, an average of \$76 to each inhabitant. A powerful impulse has recently been given to Prussian industry by the results of the Franco-German war. The increase of capital and the strengthened confidence of the capitalists in the lasting prominence of Prussia and Germany led to the establishment of a large number of new manufactories and the enlargement of many old ones. Among the new branches of industry the manufacture of beet sugar stands foremost, the number of factories in 1873 amounting to 257. The introduction of the cotton manufacture has been attended with great losses. In 1846 the number of spindles was 194,290; in 1856, 289,000; in 1866, about 600,000. The linen manufacture has been developed to the greatest perfection in Silesia and Westphalia, and has of late assumed larger dimensions in the provinces of Hanover and Hesse-Nassau. Among the most prosperous manufactures of the kingdom is that of woollen goods, which is chiefly carried on in the two Rhenish districts of Aix-la-Chapelle and Düsseldorf and in the provinces of Brandenburg, Saxony, and Silesia. Large manufactories of silks are found in the Rhine province, Westphalia, and Brandenburg. Hardware of all kinds is manufactured in all the provinces except Prussia proper and Posen. The machine shops of Berlin rival the largest establishments of the kind in England, while the great iron and steel works of Krupp at Essen are now the most extensive and famous in the world. Solingen and Suhl are celebrated for cutlery and guns; Silesia for castings and sheet iron; Westphalia for scythes and needles. In 1868 the iron works of Prussia produced 10,279,000 cwt. of bar and rolled iron, 2,408,000 of steel, 1,781,000 of sheet iron, 862,156 of iron wire, and 3,490,000 of castings. Rapid as the increase of the production of raw iron has been, it has not been able to keep pace with the increase of consumption. The manufacture of leather,

morocco, cordovan, &c., flourishes in Saxony, in Berlin, and in Prussia proper. In the manufacture of paper the progress has been more rapid even than in textile fabrics; it is carried on in the Rhine province, Westphalia, Brandenburg, Saxony, and Silesia. Chicory and starch are manufactured principally in Saxony, tobacco in all parts of the kingdom. The most extensive copper and brass manufacturing establishments are found in Saxony and on the Rhine. Glass ware, crockery, stoneware, and china are produced in large quantities, principally in the central and eastern provinces. The porcelain of Berlin rivals the best made in France. Tassels, fringes, trimmings, &c., are manufactured at Breslau, Magdeburg, Cologne, and Berlin; furniture and pianos at Berlin.—The postal arrangements of Prussia, which have long been celebrated for their admirable convenience, economy, and exactness, have now, in common with those of the other states of the German empire, passed into the hands of the imperial government, by which however their leading features are retained. The telegraphs, all of which are under state control, followed the same course. The aggregate length of the railway lines in operation in May, 1874, was 9,042 m., of which 2,520 m. were comprised in roads belonging to the state, 1,611 m. in roads of private companies managed by the state, and 4,911 m. in roads belonging to and managed by private companies. The rolling stock in 1872 consisted of 4,327 locomotives, 6,794 passenger cars, and 95,296 freight cars. The number of passengers carried over the roads in 1872 was 86,442,679; total freight, 1,550,000,000 cwt. In 1873 the commercial marine comprised 2,961 vessels (including river steamers), with an aggregate tonnage of 489,890, of which 1,104 were steamers. The entrances at the various ports in 1872 were 56,974 vessels, tonnage 4,613,228; clearances, 55,083, tonnage 4,611,598.—Until 1855 the Royal bank at Berlin (which had been transformed into a joint stock bank in 1846) was the only bank of issue. In December, 1873, the number of banks of issue was 12. The circulation of the Royal bank, which until 1850 had not exceeded \$15,000,000, rose to \$50,000,000 in 1857, and in December, 1873, amounted to \$215,000,000. In all the principal cities there are branches of the Royal bank. The Frankfort bank, in Frankfort-on-the-Main, had a circulation of about \$10,000,000, and the Hanover bank of \$2,800,000; the note circulation of each of the other banks does not exceed \$700,000. A peculiar moneyed institution of Prussia, first introduced by Frederick the Great, but since imitated in other countries, is the real estate bank (*Hypothekenbank*), originally intended to save the large landholders from the usurious practices of money lenders. These banks issue transferable mortgage bonds to the amount of one half or two thirds of the value of landed estates, the bank or association of landholders guaranteeing the principal and interest to the

holders of the bonds. The aggregate amount of such bonds exceeds \$330,000,000. The association of capital for commercial and industrial purposes, not including railways, turnpikes, or canals, has of late greatly increased. In December, 1872, the total number of companies was 1,041, of which 762 had been founded since June 11, 1870, the date of the promulgation of the new law on stock companies. Of the latter number 126 were banking, 28 insurance, 108 mining, 6 steamship, and 293 manufacturing companies. A large number of these companies disappeared again in consequence of the financial crisis of 1873-'4. The savings banks of Prussia are municipal institutions, belonging to the towns (*städtische Sparbanken*) or to the circles (*Kreis-sparbanken*). The aggregate deposits in them amount to more than \$113,000,000.—The system of public education in Prussia is one of the most thorough in the world. Instruction in the common branches is compulsory. It is difficult in Prussia to find adult persons unable to read. The number of common schools in 1873 was about 35,000, with over 3,700,000 pupils. The number of "middle schools," academies, apprentices' schools, Sunday schools, and industrial schools is very large, and increasing from year to year. In 1873 there were 32 provincial technical schools (*Gewerbeschulen*). The middle schools embraced 218 *Gymnasien* (classical colleges), 3 *Realgymnasien*, 73 *Progymnasien* (preparatory colleges) and Latin schools, and 246 *Realschulen* and *höhere Bürgerschulen*, having together 120,000 pupils. There were nine universities, at Berlin, Königsberg, Halle, Breslau, Greifswald, Marburg, Göttingen, Bonn, and Kiel, with more than 800 teachers and 9,600 students; two Roman Catholic academies; and 128 normal schools, 94 for male and 34 for female teachers. Besides these there are numerous educational institutions for special branches of science, as theological seminaries connected with the universities and at the seats of the Roman Catholic bishops, a philosophical academy at Paderborn, a polytechnic institution and an academy of architecture at Berlin, polytechnic schools at Hanover and Aix-la-Chapelle, mining academies at Berlin and Clausthal, academies of veterinary surgery at Berlin and Hanover, academies of forest culture at Neustadt-Eberswalde and Münden, agricultural colleges at Eldena, Proskau, Poppeisdorf, and Göttingen-Weende, 34 agricultural schools, and a great number of private commercial academies. All educational institutions are controlled, more or less directly, by the government. Even private teachers must submit to a thorough examination before they are permitted to open schools. The common schools are sustained and managed by the municipal corporations, but the teachers are appointed by government. Of charitable institutions, there are 18 deaf-mute asylums, 16 asylums for the blind, several orphan asylums and nurseries, Bible and missionary societies,

&c. The highest branches of scientific culture are fostered by the royal academy of Berlin and numerous associations of scholars. There are large public libraries in all the principal cities; observatories and botanical gardens are connected with the universities; a zoological garden is kept near Berlin. The fine arts are taught by the royal academy of art at Berlin, the art academies of Düsseldorf, Königsberg, Hanau, and Cassel, and five art schools. The number of musical academies and musical societies is enormous. The press of Prussia is treated in the article NEWSPAPERS, vol. xii., p. 338.—The dominant religion in Prussia is the Protestant. The two principal Protestant denominations, the Lutheran and the Reformed or Calvinistic church, united in 1817, assuming the common designation of Evangelical church. According to the census of 1871, there were in Prussia 16,041,215 Evangelical Christians, 8,268,309 Roman Catholics, 325,565 Jews, and 54,903 of smaller religious sects. Included in the latter number were 20,009 Lutheran dissenters, 14,052 Mennonites, 9,375 Baptists, 2,531 Free Religionists, 1,354 German Catholics, and 987 Free Congregationalists. The Old Catholics in 1874 numbered about 18,000. The Evangelical church constitutes a majority in the provinces of Schleswig-Holstein (99 per cent.), Pomerania (97), Brandenburg (95), Saxony (93), Hanover (87), Hesse-Nassau (70), and Prussia (70); the Roman Catholic church in Hohenzollern (96 per cent.), the Rhine province (73), Posen (64), Westphalia (53), and Silesia (51). The Evangelical church is governed by the supreme ecclesiastical council at Berlin (established in 1850) in all spiritual matters, and by the ministry of public worship in temporal affairs. Each province has a consistory and a superintendent general, and is divided into dioceses, at the head of which stand superintendents. The Roman Catholic church has 2 archbishoprics (Gnesen-Posen and Cologne) and 10 bishoprics (Culm, Ermeland, Breslau, Münster, Paderborn, Treves, Osnabrück, Hildesheim, Fulda, and Limburg). Of the Jews fully one half live in the eastern (formerly Polish) provinces. The members of all churches recognized by government enjoy equal civil rights. The Old Catholics have been recognized by the government as a part of the Catholic church, and the bishop elected by them as a bishop of the Catholic church. Other denominations (Baptists, Methodists, German Catholics, and Free Congregationalists) are barely tolerated, though the constitution guarantees full religious liberty.—Prussia is a hereditary constitutional monarchy. The constitution was promulgated Jan. 31, 1850, but has since received various modifications, the last, in reference to the ecclesiastical provisions, in May, 1875. In the territories annexed in 1866, the Prussian constitution was introduced on Oct. 1, 1867. It guarantees to all citizens equality in civil rights, the right of habeas corpus, religious liberty, freedom of

the press, &c. The king is the chief executive, clothed with all prerogatives of monarchical power. He administers the government by the advice of nine responsible ministers, viz.: of the royal household, of foreign affairs, of finances, of public worship, education, and health, of commerce, industry, and public works, of the interior, of justice, of war, and of agriculture. The legislature (*Landtag*) consists of a house of lords (*Herrenhaus*) and a house of deputies (*Abgeordnetenhaus*). The former embraces: 1, all princes of royal blood, including the princes of the formerly sovereign houses of Hohenzollern-Hechingen and Hohenzollern-Sigmaringen; 2, the chiefs of the mediatized princely houses, recognized by the congress of Vienna, to the number of 16 in Prussia; 3, the heads of the territorial nobility, numbering about 50 members; 4, eight titled noblemen, elected in the eight old provinces by the resident landowners; 5, the representatives of the universities, the heads of the chapters, and the burgomasters of towns with more than 50,000 inhabitants; 6, an unlimited number of members appointed by the king for life or for a restricted period. The chamber of deputies consists of 432 members, 352 for the old provinces, and the remainder for the new territories annexed in 1866. The deputies are elected by indirect universal suffrage for a term of three years. The king has an absolute veto power. At the head of the political administration of each of the 11 provinces stands an *Oberpräsident* (chief president). The provinces are divided into administrative districts called *Regierungsbezirke*, except in the province of Hanover, where the former division into *Landdrosteien* is retained. At the head of each *Regierungsbezirk* stands a *Regierungspräsident*, at the head of a *Landdrostei* a *Landdrost*. The number of administrative districts is 34, besides the city of Berlin and Hohenzollern, each of which forms a separate district. The districts are divided into *Kreise* or circles, except Hohenzollern, which is divided into four *Oberamtsbezirke*. At the head of a circle in all the old and some of the new provinces is a *Landrath*; in parts of the new territories, the former titles of the heads of subdivisions, like *Kreishauptmann* and *Amtshauptmann*, have been retained. Provincial assemblies exist, but their powers are only advisory. They cannot originate any measures, and must not even advise the government upon any subject unless called upon to do so. Their principal duty is to apportion the taxes to be levied from the provinces. The police throughout the kingdom is administered by the government. The administration of justice has been completely reorganized since 1848. Publicity of judicial proceedings, trial by jury, and a new criminal code have been introduced, and all exceptional jurisdiction has been abolished. In Rhenish Prussia the *code Napoléon* and the French legal procedure, which were introduced under the rule of Napoleon, have been main-

tained. In the other provinces there are city or district courts, and 26 courts of appeal. The chief tribunal at Berlin is the court of last resort for all parts of the kingdom.—Financially Prussia is in a flourishing condition, and its financial administration is excellent. The annexation of large territories in 1866 and the establishment of the German empire under the Prussian dynasty, in 1871, to whose budget some of the revenues as well as the expenditures of Prussia were transferred, render a comparison of the Prussian budgets of the years before 1867 with those of the following years of little value. The estimates of public revenue and expenditure submitted by the government to the chambers are always prepared to show an even balance; but in recent years the actual revenue has always largely exceeded the estimate, and shown even in years of war a constant and increasing surplus. In the budgets of 1868 to 1874, revenue and expenditures were each estimated at the following amounts: 1868, \$115,000,000; 1869, \$120,600,000; 1870, \$121,200,000; 1871, \$124,500,000; 1872, \$134,600,000; 1873, \$151,200,000; 1874, \$167,500,000. The actual surplus amounted in 1870 to \$6,700,000, in 1871 to \$7,200,000, and in 1872 to \$8,900,000. Of late the income from railways and other state undertakings, such as mines, has been largely increasing, showing a tendency to become in the course of time larger than that from taxation, direct or indirect. In the estimates for 1874, the revenue of the ministry of commerce, chiefly from the railways and mines, was more than two fifths of the entire government receipts. The exemption of a large number of landed proprietors (noblemen) from taxation on real estate was abolished in 1861, but the actual payment of taxes by them did not begin till 1865. The public debt of Prussia, which in 1787 was only \$32,250,000, amounted in 1820 to \$152,491,000. In 1847 it had been reduced to \$98,000,000, but in 1862 it again amounted to \$175,700,000. On the annexation of Schleswig-Holstein, Hanover, Hesse-Cassel, Nassau, and Frankfort to Prussia, it was arranged that the incorporation of the debts of these states with that of Prussia should take place at some future period. This had not yet been done in 1874. The aggregate debt of the entire monarchy in that year amounted to \$259,400,000, of which \$107,900,000 was railway debt. The interest on the latter debt is paid out of the profits of the state lines, the yearly increasing dividends of which likewise create a sinking fund for the gradual extinction of the debt.—The Prussian military system, so elaborate and thorough that it has been chiefly instrumental in giving the state its present leadership among European countries, was in 1871 extended to the whole empire, and the Prussian became a part of the imperial army. The navy of Prussia has in the same way become the chief part of the imperial naval force. (See GERMANY, vol. vii., pp. 750, 751.)

—The country which gave its name to the kingdom of Prussia, of which it is now only a province, was in antiquity probably known to the Phœnicians, who either in their ships or through trading posts procured amber from its Baltic shores. The aborigines, a Lettic tribe kindred to the Lithuanians, appear to have been peaceable and quiet, and acquainted with agriculture. During the first centuries of the Christian era they became dependent upon the Goths, who overran their country. In the 10th century they are first mentioned under the name of Borussi or Porussi. Their religion was polytheism, and human sacrifices were not uncommon. Bishop Adalbert, who attempted to convert them to Christianity, was slain by them while hewing down their sacred oak tree, in A. D. 997. Boleslas I. of Poland invaded their country and compelled them to profess the Christian faith in 1015, but neither he nor his immediate successors could retain a hold upon them. A large army which Boleslas IV. led against them was totally annihilated, and the Prussians even held a part of Poland in subjection for some time. In 1219 they repelled a crusade sent against them from Germany, and soon became the terror of all neighboring countries. The Teutonic knights finally conquered Prussia (1230-'83), founded cities, introduced German colonists and German laws, and by their firm rule made Prussia one of the most flourishing countries of its time. (See TEUTONIC KNIGHTS.) But about the middle of the 15th century the demoralization of the knights, their continual wars with Poland and Lithuania, and their reckless exactions created a powerful opposition. The nobility and the municipalities obtained the assistance of the king of Poland, Casimir IV., and by a war of 12 years' duration (1454-'66) compelled the order to cede western Prussia and Ermeland to Poland. The remainder was left to them as a fief of Poland. In 1511 the margrave Albert of Brandenburg was elected grand master of the order. Having vainly striven to throw off the Polish rule, he turned Protestant, and in 1525 accepted Prussia as a duchy from Poland. His son Albert Frederick becoming insane, the duchy was governed by his relatives, of whom John Sigismund, elector of Brandenburg, inherited it in 1618. He was a descendant of Frederick of Hohenzollern, burgrave of Nuremberg, who had become possessor of Brandenburg in 1415 by foreclosure of mortgage. (See BRANDENBURG, and HOHENZOLLERN.) The electorate of Brandenburg, not Prussia proper, must be considered the nucleus of the present monarchy of that name. The electorate, though frequently divided by the descendants of Frederick, played a conspicuous part in the history of Germany, especially during the reformation. Frederick I. (1415-'40) subdued the robber knights, and obtained some additional territory from Pomerania and Mecklenburg, but succumbed to the Hussites, who

devastated his country with fire and sword in 1432. Frederick II. (1440-'70) enlarged his possessions by purchases from neighboring states, but was unfortunate in his attempts to conquer Lusatia from Bohemia and Stettin from Pomerania. Albert Achilles (1470-'86) and John Cicero (1486-'99) contended energetically against the usurpations of the lords, and promoted industry, commerce, and science. The two younger brothers of the latter received the Franconian possessions of their father, and founded the two branch lines of the house of Brandenburg, Anspach and Baireuth. Joachim I. Nestor (1499-1535) was noted as a scholar, and also as one of the most violent opponents of the reformation, and a persecutor of the Jews, of whom he had many burned at the stake or exiled. Joachim II. Hector (1535-'71) became a Protestant, secularized the bishoprics of Brandenburg, Havelberg, and Lebus, founded many educational or charitable institutions with the proceeds of the church property, and concluded a treaty of mutual inheritance with the duke of Liegnitz in Silesia, which two centuries later became the foundation of the Prussian claims on Silesia. John George I. (1571-'98) expelled the Jews who had been readmitted by his predecessor, but invited the exiled Protestants from the Netherlands into his country, and by wise economy greatly improved the financial condition of his state. Joachim Frederick (1598-1608) acquired by marriage a claim on the duchy of Prussia, which his son John Sigismund (1608-'19) permanently united to the electorate of Brandenburg, having previously, after the death of the duke of Jülich, acquired Cleves and other possessions. Under the reign of George William (1619-'40), Brandenburg and Prussia suffered terribly from the thirty years' war. Having adopted a policy of neutrality, the elector was looked upon as an enemy by both contending parties. Prussia was ravaged by Swedes and Poles, Brandenburg by the imperial armies and those of the league, and during 12 years by the Swedes. From the lowest depth of misery and desolation the country was raised by the energy and wisdom of Frederick William, the Great Elector (1640-'88). By marking out a vigorous and independent policy against France, Sweden, and Poland, and shrewdly taking advantage of dissensions among his enemies, he enlarged his dominions and obtained a position but little below that of the great powers of Europe. Of Prussia he made a sovereign duchy, severing its connection with Poland. At his death his possessions had increased to 42,000 sq. m. with 1,500,000 inhabitants. His son Frederick, the third elector of that name (1688-1713), by consent of the German emperor, assumed the title of king of Prussia, and was crowned as such Jan. 18, 1701. He acquired a few small territories, the principality of Neuchâtel in Switzerland among the rest. His son Frederick William I. (1713-'40) acquired from Sweden a part of Pomerania,

with Stettin, increasing the area of the country to 48,000 sq. m. He left to his son Frederick II., the Great (1740-'86), \$6,000,000 over and above all debts, and an army of 70,000 men, the best disciplined in all Europe. With these means Frederick began a war of conquest, and wrested Silesia from Austria. By a wise and prudent administration he strengthened and consolidated his kingdom, and elevated it to the rank of a great power by successfully resisting during a sanguinary war of seven years' duration (1756-'63) the combined aggressions of Austria, France, and Russia. In 1772 he took part in the first partition of Poland. To his successor he left a treasure of \$50,000,000, an army of 220,000 men, and a territory of 77,000 sq. m. On his accession he had 2,240,000 subjects, and at his death the number exceeded 6,000,000. Frederick William II. (1786-'97), though his reign was weak, harmful, and occupied by imprudent and unsuccessful wars in alliance with Austria against revolutionary France, failed to destroy the prestige of Prussia, and by participating in the second and third partitions of Poland added to his possessions 40,000 sq. m. Frederick William III. (1797-1840), by a weak and vacillating policy, isolated Prussia and encountered the wrath of Napoleon, who, after the ignominious defeat of the Prussian armies at Jena in 1806, reduced the kingdom to less than half its former area. For six years Prussia was cruelly oppressed by Napoleon, who did his utmost to reduce the kingdom to insignificance. But during this period the statesmen of Prussia laid the foundation of its subsequent greatness by unfettering labor and commerce, by granting municipal self-government, and basing the military power of the state upon the people. After the downfall of Napoleon most of its former possessions were restored to Prussia, and in addition to them it acquired parts of the kingdom of Saxony and of Pomerania, Berg, Jülich, and several valuable territories on the Rhine. The promise of a liberal constitution, given by the king to his people, was not kept. The political condition settled down into a sort of patriarchal despotism. The establishment of the Zollverein was the only wise and statesmanlike measure during 25 years of peace. Frederick William IV. (1840-'61), who had great natural talents and scholarship, but was weak and pusillanimous, destroyed almost totally the moral prestige of Prussia, and threw away the opportunity, offered to him by the revolution of 1848, of becoming the head of a united German nation. For nearly 10 years under his reign the reactionary party held almost absolute sway, though the state had been converted into a constitutional monarchy. In 1857 his mental faculties gave way, and his brother William was intrusted with the regency. Frederick William died Jan. 2, 1861, and was succeeded by the regent as William I. The accession of the new king, whose career had already shown him to be heartily devoted

to the long cherished plan of securing complete Prussian leadership in Germany, found the country in the very height of jealous dissensions with Austria, which had become particularly prominent after the peace of Villafranca between Austria and France (1859). The acts which this mutual jealousy inspired, and by which every possible factor was brought into the struggle for control, are described at length in the article GERMANY. For several years there was no open rupture; it was only with the entrance of Bismarck into the Prussian cabinet as minister of foreign affairs, in 1862, and the uncompromising attitude then assumed in certain questions of German politics, that the breach seemed to become irreparable; and no sooner had it been thus widened than the Schleswig-Holstein complication (see AUSTRIA, DENMARK, GERMANY, and SCHLESWIG-HOLSTEIN) arose to present a possible and plausible *casus belli*. In spite of many attempts at mediation, the attitude of the great powers became more and more hostile, and after several arbitrary acts on both sides, the convention of Gastein, which gave the occupation of Holstein to Austria and that of Schleswig to Prussia, but which it seemed evident neither power would long adhere to, placed affairs in precisely the position where another step on either side must mean war. The convention was signed on Aug. 14, 1865; but as early as January, 1866, the conduct of the officials in the duchies gave cause for a new quarrel. In April Prussia made an alliance with Italy, and began to arm. The smaller states of Germany generally sided with Austria. On June 1 Austria arbitrarily took the question of the Danish duchies out of the limits of the Gastein agreement, by suddenly declaring it to be referred to the federal diet; and Prussia, regarding this as a breach of treaty, marched its troops into Holstein, and proposed to restore the joint occupation of both duchies. Austria declared this act to be a violation of the federal constitution, and the federal diet, acting entirely under its leadership, ordered (June 14) the mobilization of all the federal troops except those of Prussia. On June 15 Prussia summoned Hanover, Saxony, and Hesse-Cassel to retract their action at the diet; they refused, and on the next day Prussian troops occupied their territory, and war was begun. The conflict which followed was a remarkable proof of the condition of preparation in which the Prussian state had placed itself; and under the name of the "seven weeks' war" it has become famous as one of the shortest but most decisive struggles in history. On June 22 and 23 the three divisions of the Prussian main army advanced toward the frontiers of Bohemia from two directions—in Silesia under the command of the Prussian crown prince, in Saxony under that of Prince Frederick Charles of Prussia and Gen. Herwarth von Bittenfeld. From the 26th to the 29th various minor engagements took place along the lines, at Podol,

Hühnerwasser, Münchengrätz, Gitschin, Trautenau, Nachod, Königinhof, &c. In the mean while, on the 28th, the Hanoverian army, cut off from reinforcements or means of retreat by the Prussian forces about it, had surrendered at Langensalza. On July 1 the Prussian armies were united near Königrätz; and on the 3d they encountered at Sadowa, near by, the main Austrian army under Benedek, and achieved the decisive victory of the war. (See SADOWA.) The armies of Austria at once retreated to the south, and the northern provinces were left in the power of the enemy. While these things were in progress, a simultaneous campaign was carried on by Prussia in western Germany, but with far less bloodshed; an army under Gen. Vogel von Falkenstein had opposed the Bavarians and the army of the smaller states, forced them to retreat after a battle near Kissingen on July 10, met an Austrian division near Aschaffenburg on the 14th, and entered Frankfurt on the 16th. Another portion of the "army of the Main," under Gen. Manteuffel, met the 7th and 8th corps of the federal army, July 24-27, at Tauberbischofsheim, Helmstadt, and Würzburg, and won minor victories. On the 26th preliminary negotiations for peace were begun at Nikolsburg, and a truce with Austria was declared; this was followed by truces with Bavaria, Hesse-Darmstadt, Würtemberg, and Baden (Aug. 1-3). Definite treaties of peace followed with Würtemberg (Aug. 13), Baden (Aug. 17), Bavaria (Aug. 22), and Austria (the peace of Prague, Aug. 23). The "seven weeks' war," and the treaty which ended it, placed Prussia at the head of Germany, and marked it as one of the first military powers of Europe. The treaty of Prague virtually established a new federation of German states, soon definitely formed (Aug. 18 to Oct. 21) into the "North German Confederation" (*Norddeutscher Bund*), including all the states north of the Main. It shut out Austria from Germany, and left the South German states to take their own course as to the establishment of a *Bund* between themselves. But Prussia gained an aggrandizement of territory as well as of prestige; for it annexed Schleswig-Holstein, Hanover, Hesse-Cassel, Nassau, and Frankfurt, and thus not only extended its boundaries, but removed the principal obstacles to its territorial unity. The chief measures of Prussian politics from the close of the war of 1866 till 1870 are again treated in the article GERMANY. The minor measures of its politics during this period comprised treaties on points of administration, posts, military affairs, &c., with the other states, and regulation of its own educational, industrial, and financial affairs. The part of Prussia in the Franco-German war of 1870-71 (see FRANCE, and GERMANY) is inextricably involved with that of the whole German nation. The conflict served to precipitate the solution of the question which had always been the aim of the king and Bismarck: German unity

under Prussian leadership. On Jan. 18, 1871, King William was crowned at Versailles as emperor of Germany, and on March 21 the first German Reichstag assembled at Berlin. From 1871 to 1874 Prussia had undertaken no important measures independently of the rest of Germany, and its most recent history is therefore contained in the article on the empire. (See also WILLIAM I., of Prussia and Germany, and for fuller accounts on previous periods of Prussian history the notices on the principal monarchs under the head of FREDERICK.)

PRUSSIAN BLUE. See POTASSIUM.

PRUSSIA PROPER, a great division of the Prussian kingdom, comprising East or Ducal Prussia, and West or Royal Prussia, now officially united into one province; area, 24,114 sq. m.; pop. in 1871, 3,137,545. East Prussia is bounded N. E., E., and S. by Russia (Courland, Lithuania, and Poland), W. by West Prussia, and N. W. by the Baltic. Its surface is low and almost uniformly level, and there are numerous lakes formed by the rivers, the fall being insufficient to carry their waters to the ocean. The most important streams are the Memel or Niemen, which empties into a vast estuary or lagoon called the Kurisches Haff, the Pregel, and the Passarge. The greater part of the soil is fertile, and the principal crop is potatoes. Nearly one third of the land is covered with forests. Fruit, flax, hemp, tobacco, grain, live stock, and fowls are largely produced, game is abundant, and amber is found in considerable quantities. East Prussia comprises the administrative districts of Königsberg and Gumbinnen. Most of the inhabitants are Germans.—West Prussia is bounded N. by the Baltic, E. by East Prussia, S. by Russian Poland and Posen, and W. by Brandenburg and Pomerania. The surface, soil, and productions are like those of East Prussia. The principal rivers are the Vistula, whose E. mouth, the Nogat, enters the Frisches Haff, the Drewenz, and the Brahe. There are numerous inland lakes, but they are not so large as those of East Prussia. This division comprises the administrative districts of Dantzic and Marienwerder. About 67 per cent. of the inhabitants are Germans, and 33 per cent. Poles.—Prussia proper was conquered and Christianized in the 13th century by the Teutonic knights. In 1466 they were forced by Casimir IV. to cede West Prussia to Poland, while keeping East Prussia as a fief of that kingdom. The latter division, when converted into a duchy by the last grand master of the order, Albert of Brandenburg (1511), was designated as Ducal Prussia, and was united with Brandenburg by the elector John Sigismund (1618). Western or Royal Prussia was severed from Poland, in the first partition of that kingdom (1772), by Frederick the Great, with the exception of the cities of Dantzic and Thorn, which Frederick William II. received in the second partition (1793).

PRUSSIC ACID. See HYDROCYANIC ACID.

PRUTH (anc. *Poras*), a river of Europe, which rises in the N. E. Carpathians, on the boundary between the Hungarian county of Mármaros and Galicia, flows E. through the latter country and Bukowina, and S. S. E. along the boundary line of Roumania and Bessarabia, and joins the Danube at Reni, near the delta of the latter river. The length of its course is about 350 m. The Pruth figures conspicuously in the history of every Turko-Russian war since the times of Peter the Great, who in 1711 narrowly escaped being captured on its banks, with his army.

PRYNNE, William, an English political writer, born at Swainswick, near Bath, in 1600, died in London, Oct. 24, 1669. He graduated at Oriel college, Oxford, in 1620, studied law, and was admitted a barrister of Lincoln's Inn. Having become a Puritan, he published pamphlets against Arminianism; and some passages in one entitled "*Histriomastix, the Player's Scourge*" (1632), appearing to reflect upon the king and queen, Bishop Laud brought him before the star chamber, and by that court he was excluded from Lincoln's Inn, and condemned to pay a fine of £5,000, to have his ears cut off, to stand in the pillory at Westminster and Cheapside, and to be imprisoned during the king's pleasure. His work was also ordered to be burned before his eyes by the common hangman. This sentence was rigorously carried out, but from his prison he continued to issue tracts against the prelates. The publication of one of these, in 1637, entitled "*News from Ipswich*," stirred up anew the anger of Laud, and Prynne was again summoned before the star chamber, and fined £5,000. The remains of his ears were cut off, and the letters S. L. (seditious libeller) were branded on both cheeks. At the execution of this sentence in the palace yard, and afterward on his way to his prison, Carnarvon castle, a great crowd was present, which manifested its sympathy and respect for the sufferer. Such numbers also visited the castle, that after a residence of ten weeks he was removed by an illegal order to the castle of Mont Orgueil in the island of Jersey. On Nov. 7, 1640, he was released by an order of the house of commons, his sentence being reversed, and damages to the amount of £5,000 being awarded him against his judges. His entrance into London had the appearance of a triumphal procession. Soon after he became a member of parliament for Newport in Cornwall, and in 1647 he was elected recorder of Bath. He took a prominent part in the proceedings of the long parliament, zealously espousing the cause of the Presbyterians and opposing the Independents. Just before the king's trial he was ordered into the custody of the sergeant at arms for "denying the supremacy of parliament," and on Dec. 6, 1648, he was arrested by the army and ejected from the house. He now became a bitter opponent of Cromwell, and published articles of so virulent a character that he was twice imprisoned. He

was discharged from his office of recorder of Bath in 1654, but was reelected after the restoration. He was one of the excluded members who sat in the house of commons early in 1660, and was zealous in furthering the restoration, after which he was appointed keeper of records in the tower. Wood, in his *Athenæ Oxonienses*, gives a catalogue of his writings, which comprises nearly 200 volumes. The most valuable are his "Collection of Records," "Calendar of Parliamentary Writs," and "Observations on the Fourth Part of Coke's Institutes." His "Records" he intended to bring down as late as the reign of Elizabeth, but he lived only long enough to complete the work as far as that of Henry III.

PRZEMYSŁ, a town of Austrian Galicia, on the San, at the junction of the Lemberg and Cracow and the Hungaro-Galician railways, 55 m. W. of Lemberg; pop. in 1870, 15,184 (against 9,800 in 1857), including more than 5,000 Jews. It is one of the oldest towns of Poland. It has many Gothic churches, including two ancient cathedrals, is the seat of a Catholic and a Greek United bishop, and has a gymnasium and other schools. The principal trade is in timber, leather, and linens.

PSALMANAZAR, *George*, the assumed name of a French impostor, born about 1679, died in London in 1753 or 1763. He travelled over various parts of France, Germany, and the Netherlands; was a soldier, a beggar, and a servant, pretending at first to be a Japanese and afterward a Formosan; and at length went to England with one Innes, a chaplain in a Scotch regiment, who claimed the credit of converting him to Christianity. In 1704 he published at London a pretended "History and Description of the Island of Formosa off the Coast of China," in which the description of the island was given with such apparent fidelity, the manners and customs were illustrated with so many engravings, and such copious specimens were given of a new language, that the belief in the story was general until the author revealed the imposition. He now applied himself seriously to study, and wrote a large portion of the "Universal History," a true account as far as known of Formosa for the "Complete System of Geography," an "Essay on Miracles," and a version of the Psalms. He left in manuscript his own memoirs, published in London in 1765.

PSALMS, *Book of* (in the Septuagint, *Ψαλμοί*, hymns sung to the accompaniment of stringed instruments; in Hebrew collections, *Tehillim*, praise songs), one of the canonical books of the Old Testament, containing a copious collection of religious songs. Religious poetry among the Hebrews, as among the oriental nations in general, can be traced to a high antiquity. The Pentateuch contains several hymns and fragments of hymns; in the book of Psalms we find one psalm which is ascribed to Moses; and in the time of the judges we meet with the beautiful song of Deborah

(Judges v.). But the religious poetry of the Hebrews attained its principal development through King David, who is represented in the Scriptures as having practised it from early youth until his death, and in particular as having introduced the singing of hymns into the service in the tabernacle. In the Hebrew original 73 psalms are ascribed to David, but none of the old ecclesiastical translations, as the Septuagint, the Vulgate, and the Peshito, agree in this respect. Besides Moses and David, several other authors of psalms are named in the headings; thus, 2 psalms are ascribed to Solomon, 12 to Asaph, 11 to the sons of Korah, a Levitic family, and one each to Heman and Ethan. The Alexandrine and Syriac versions mention also the prophets Haggai and Zechariah as the authors of some psalms.—The collection of psalms, in the form in which it appears in the Old Testament, cannot have been completed until after the captivity, as some of the psalms are obviously of subsequent origin. According to Hitzig, Lengerke, and Olshausen, some of the psalms belong to a time as late as that of the Maccabees. The possibility of Maccabean psalms is admitted by Delitzsch, while their existence is denied by Hengstenberg, Hävernick, Keil, Ewald, and others. Particular collections, which were afterward embodied in the book of Psalms, may possibly have existed as early as the time of David. The book of Psalms is, according to the analogy of the Pentateuch, divided into five books, each of which closes with a doxology. The second book has a postscript, which seems to have been the conclusion of an old particular collection. The Septuagint and the Vulgate, which follows it, differ somewhat from the Hebrew in numbering the psalms, the difference beginning with the 10th and extending to the 147th; the entire number in all these is 150.—The contents of the book of Psalms are manifold. With regard to their object, they may be divided into six classes: 1, hymns to God, in which he is praised as the creator, preserver, and governor of the world, and in particular as the protector of his chosen people; 2, national psalms, in which the people are reminded of the ancient history of Israel from the time of the patriarchs, especially of the history of Moses, of the many favors received from God, of the occupation of the promised land, of the signal assistance of God, and of the gratitude therefore due to him; 3, the king's psalms, in which the theocratic king is praised as the representative of Jehovah, and the assistance of the Lord is invoked for him; 4, moral hymns, in which the fate of the pious and the wicked is described; 5, the psalms of lamentation, in which, sometimes by individuals, sometimes by the entire people, misery and calamity, especially oppression experienced from foreign or domestic foes, are lamented, with a prayer to God for deliverance; a subdivision of this class is the penitential psalms, describing the sufferings

of the psalmist as deserved, recognizing the committed sin, and praying for pardon; 6, prophetic psalms, which have reference to a Messianic future. A great difference of opinion prevails among exegetical writers as to the number of psalms belonging to this last class, and theologians of the rationalistic school have maintained that a directly predictive character cannot be claimed for a single passage in the Psalms.—The collection of psalms seems to have come at once into public use at divine service both as prayers and hymns. The singers who were appointed by David for the service of the sanctuary sang psalms. In the time of Hezekiah, psalms of David and Asaph are recorded as having been sung at religious solemnities (2 Chron. xxix. 30), and songs of David were also sung in the second temple, after the captivity (Ezra iii. 10). In the Christian church the book of Psalms had likewise from the beginning a great importance. Christ himself, after the celebration of the last supper, sang psalms with his disciples; and soon afterward, when on the cross, he used the words of a psalm. Paul and Silas praised God in psalms in the dungeon at Philippi, and Paul exhorts the Ephesians and Philippians to praise the Lord with psalms and spiritual songs. The early Christians used the psalms both in public service and in their private devotions, and the church soon made them a prominent part of the liturgical books, in particular of the breviary. In the Protestant churches the psalms have always been extensively used for congregational singing, and some denominations, as the Reformed Presbyterian church, do not allow in divine service the use of any other religious hymns.—On account of the significance which has always been attached to the book of Psalms, it has in modern times called forth a larger number of commentaries than any other Biblical book. Le Long, in his *Bibliotheca Sacra* (Paris, 1723), enumerates more than 500 commentaries, exclusive of those which form parts of larger works, as well as of the commentaries on a part of the book of Psalms. Among the English commentaries the work of Bishop Horne has not been superseded for popular use, though its critical value is small. Of more critical worth are: Phillips, "The Psalms in Hebrew, with a Critical, Exegetical, and Philological Commentary" (2 vols., London, 1846); and Browne, "The Book of Psalms, a new Translation, with Introduction and Notes Explanatory and Critical" (2 vols., 2d ed., London, 1870). The exegetical literature of Germany is rich in excellent commentaries, of which the best known are those by De Wette, Hitzig, Hirzel, Ewald, Hengstenberg, Delitzsch (new ed., 1867), Hupfeld (4 vols., 1855-'61; new ed. by Riehm, 1867-'71), and Moll, *Der Psalter* (in Lange's *Bibelwerk*, 1869-'70). In America new translations have been published by G. R. Noyes, "A new Translation of the Book of Psalms, with an Introduction" (3d ed., 1867); J. A. Alexander,

"The Psalms Translated and Explained" (3 vols., 1850); and T. J. Conant, "A new Version of the Psalms, and Philological Notes" (in the American ed. of Lange's *Bibelwerk*, 1872).

PSALTERY (Gr. *ψαλτήριον*), a stringed musical instrument in use among the ancient Jews, and supposed to have been identical with the *nebel* mentioned in the Psalms. Burney says it resembled partly the lyre and partly the harp, but according to others it was in shape a trapezium, not unlike the dulcimer. (See DULCIMER.)

PSAMMENITUS (PSAMMETIK III.), the last king of Egypt of the 26th dynasty, succeeded his father Amasis in 526 B. C. He had scarcely begun his reign when Egypt was invaded by Cambyses, king of Persia, who defeated him near Pelusium, shut him up in Memphis, and soon forced him to surrender (525). He was at first spared, but, being suspected of treasonable designs, was condemned to put an end to his life.

PSAMMETICHUS. See EGYPT, vol. vi., p. 463.

PSKOV, or **Pleskov.** I. A W. government of European Russia, bordering on St. Petersburg, Novgorod, Tver, Smolensk, Vitebsk, and Livonia; area, inclusive of lakes, 17,067 sq. m.; pop. in 1870, 775,701. The Valdai hills traverse the S. E. part, but the surface is generally level. There are several lakes, the most important of which, Lake Pskov, forming the southern part of Lake Peipus, comes within the limits of the province on the N. W. frontier; and in the southeast there are numerous marshes. A great part of the country is covered with forests of pine, which yield large quantities of pitch. The principal crops are rye, oats, barley, and pulse. Hemp and flax are cultivated. The only important manufacture is leather, and the inhabitants excel in dressing skins. The population is chiefly of Russian origin, but there are a few of other races, including some Mohammedans. II. A city, capital of the government, situated on the left bank of the Velikaya, about 5 m. from its mouth in Lake Pskov, and on the St. Petersburg and Warsaw railway, 165 m. S. S. W. of St. Petersburg; pop. in 1867, 12,981. It is enclosed by a wall 5 m. in circuit, and the Kremlin, or citadel, stands in the centre. It is the seat of a Greek archbishop, whose diocese embraces also the governments of Livonia and Courland, and has a cathedral and about 30 other churches, several of which are in a ruinous condition, three convents, several schools, and some charitable institutions. There are many tanneries, and a brisk trade is carried on in lumber, hemp and flax. Pskov is very conspicuous in the early history of Russia. It has been often besieged; in 1614 Gustavus Adolphus was obliged to retire from before its walls.

PSYCHE (Gr. *ψυχή*, breath, or the soul), a character of Greek romance, generally accepted as a personification of the human soul. A certain king, says Apuleius, had three daughters,

of whom the youngest, named Psyche, was a marvel of beauty, and altars were consecrated to her that properly belonged to Venus. The anger of that goddess was excited, and she commanded her son Cupid to inspire Psyche with a passion for some frightful monster; but he himself fell in love with her, and bore her away to a delightful place, where she was visited every night by the young god, who left her at dawn. Her sisters persuaded her that he who came to her every night, and whom she had never seen, must be a loathsome creature, and urged her to destroy him while he slept; but when she brought a lamp and beheld his beauty, her joy deprived her of the power of motion, and while she stood a drop of hot oil falling from her lamp upon his shoulder awoke him. With a few words of reproach he fled. Psyche now endeavored to destroy herself, but nothing in nature would injure her. At length she came to the temple of Venus, who made her a slave. Cupid finally delivered her, and, being now sufficiently purified through suffering, she was united to her beloved by Jupiter himself. In works of art Psyche is represented with the wings of a butterfly.

PSYCHOLOGY. See PHILOSOPHY.

PTAH, or *Phthah*, one of the principal divinities of ancient Egypt. He was believed to be the author of everything visible, the father of the god of the sun, and the ruler of light and fire. His seat of adoration was at Memphis, and his temple, said to have been founded by Menes, was one of the largest and most magnificent in Lower Egypt. At Hermopolis Magna were worshipped eight children of Ptah, representing the elements, and the immediate rulers of the world. Ptah's symbol was the *scarabæus sacer*, which insect was supposed to multiply without bearing, and many monuments depict Ptah with this animal instead of a head upon the shoulders. He is sometimes represented in the diminutive form of a child or a dwarf, presumably as suggestive of his being the god of the beginning, and occasionally also in the swaddlings of a mummy, which was probably intended to suggest his attribute of immutability. The Greeks compared him to their god Hephestus. (See **VULCAN**.)

PTARMIGAN, the popular name of the gallinaceous birds of the grouse family embraced in the genus *lagopus* (Briss.), which differ from the ordinary grouse in having the legs feathered to the claws, giving somewhat the appearance of a hare's foot (whence the generic name, Gr. *λαγός*, a hare, and *πους*, foot), in the truncated tail about two thirds as long as the wings and of 16 to 18 feathers, in most of the species becoming white in winter, and in the nasal groove being densely clothed with feathers; the family characters have been given under **GROUSE**. There are six or eight species described, inhabiting the northern and snow-covered regions of both hemispheres, being one of the few genera characteristic of the arctic fauna; they are as much at home in snow as

are the web-footed birds in water, and their plumed feet enable them to run over its surface without sinking. They live in families during most of the year, and are monogamous; the females incubate, but the males assist in rearing and feeding the young; the males have a loud harsh cry, and the females cackle like a hen. They are rapid fliers, without making a whirring noise, and swift runners; they feed upon berries, buds, mosses and lichens, and even insects; their flesh is good, and their pursuit affords an exciting sport; they are very shy, but when started are easily shot on account of their regular flight. The summer plumage is varied with brown, black, and gray, most of the wing remaining white; in the males the mottling is finer and the colors brighter. It is very difficult to ascertain the exact number of species, from the rarity of specimens in summer plumage, and the absence of accurate determination of sex.—There are three well ascertained species in America. The white ptarmigan or willow grouse (*L. albus*, Aud.) is

Willow Grouse (*Lagopus albus*).

about 15½ in. long and 24½ in. in alar extent; the bill is black, very stout and convex, and broad at tip; the general plumage in summer is rufous or orange chestnut on the head and neck; feathers of back black, closely barred with yellowish brown and chestnut; most of wings and lower parts white; tail brownish black; in winter white, with black tail; no black stripes through the eye. It occurs in the northern parts of America, and is common in eastern Labrador, Newfoundland, and the Northwest territories, and in rare instances in the northern United States; it is found in open rocky grounds and among dwarf willows and birches. In winter they scratch in the snow down to the mosses and lichens on which they feed, collecting often in considerable flocks. In winter the flesh is dry, but is tender and has an agreeable aromatic flavor in summer. They breed in Labrador about the beginning of June, placing the nest under the creeping branches of low firs; the eggs are from 6 to 14, of a fawn color or rufous ground with irregular

spots of reddish brown; only one brood is raised in a season. The rock ptarmigan (*L. rupes-tris*, Leach) is 14½ in. long; the bill is slender, rather compressed at tip; in summer the feathers of the back are black banded with yellowish brown and tipped with white; in winter white, with the tail black (the four middle feathers white), and the male with a black bar from the bill through the eyes. It occurs in arctic America, rarely coming further south than lat. 63° N. in the interior, but to 58° on Hudson bay, and in the Rocky mountains, according to Richardson, to 55°; the same species is said to occur in the northern parts of the eastern hemisphere; the eggs are pale reddish brown, with darker spots, and are 1½ by 1¼ in. The white-tailed ptarmigan (*L. leucurus*, Swains.) has a slender bill, the plumage in summer blackish brown barred with brownish yellow, and in winter entirely white; it is 13 in. long and 21 in alar extent; it is found in the N. W. portions of America, and to the south along the Rocky mountains to lat. 39°.

European Ptarmigan (*Lagopus mutus*)—winter plumage.

—The common European ptarmigan (*L. mutus*, Leach) is about 15 in. long; the bill is black, short, and robust; the summer plumage is ashy brown mottled with darker spots and barred with orange yellow and dark brown on the sides of the neck and back, and the tail, with the exception of the two middle feathers, grayish white with a narrow terminal white band. It is fond of lofty and northern regions, going as far as Greenland and coming down to the highlands of Scotland; when pursued, like the other species, it is apt to dive under the soft snow; it sometimes does this for protection from the cold, and in damp weather is sometimes imprisoned and destroyed under the frozen surface of the snow; the ruffed grouse has the same habit. A species much resembling this, if not identical with it, occurs in America, in the neighborhood of Baffin bay, and has been described by Audubon as *L. Americanus*.—The Scotch ptarmigan or moorcock (*L. Scoticus*, Steph.) seems pecu-

liar to Great Britain, and is abundant in the hilly districts of Scotland; the general color is chestnut brown, with black spots on the back and undulating black lines below; the winter plumage is the same. It is highly esteemed as game; where not much pursued it is not very shy, but its plumage is so like the surrounding dark moss and heaths, that it can hardly be discovered without the aid of a pointer; it feeds upon heath tops and mountain berries.

PTERICHTHYS. See GANOIDS.

PTERODACTYL (*pterodactylus*, Cuv.; Gr. πτέρων, wing, and δάκτυλος, finger), a genus of fossil flying reptiles, possessing essentially the characters of saurians, with some only apparent relations to bats and birds. They have been divided into three genera according to the number of joints in the wing-bearing finger and the disposition of the teeth; all are characteristic of the secondary epoch, being found principally in the lithographic schists of Solenhofen, and in the oölite, lias, wealden, and chalk of Europe and the United States. In the genus *pterodactylus* the jaws had teeth even to the extremity; the skull was elongated, with the intermaxillaries large; nasal opening wide and near the middle of the muzzle, partly closed in front by a small bone as in the monitors, and with a surrounding circle of small bones and a small opening into the orbit as in birds; the lower jaw, as in crocodiles, had no coronary process, and was articulated behind the eyes; the teeth, 5 to 17 on each side, were conical, slightly arched, compressed, inserted in separate cavities, and hollowed at the base; neck of 7 stout vertebræ; dorsals 13 to 15, and, with the ribs, weak; lumbar 2 or 3, sacral 6, anchylosed together, and caudal 10 to 15; the shoulder blade and coracoid bone separate and weak; scapular arch and pelvis as in lizards, except that

Pterodactyl.

the last seems to have had marsupial bones, according to Pictet; the long bones hollow and with air openings, as in birds; humerus

short and stout, and forearm twice as long; hind limbs slender, with 5 moderate toes of the same length; 5 or 6 bones in the wrist, 5 metacarpals, 5 fingers, with respectively 1, 2, 3, 4, and 4 joints; the first 4 short and with hooked nails, the external very long, equal to the neck and body, and nailless; the gape of mouth very large. This singular animal was referred to the swimming birds by Blumenbach and to the bats by Sömmering, and was determined to be a reptile by Cuvier. The nearly equal and conical teeth, very small cranial cavity, different number of joints in the fingers, and reptilian shape of sternum and scapula show that it was not a bat-like mammal; the existence of teeth, the small number of the vertebræ in the neck, the thinness of the ribs and tail and the absence of recurrent processes in the latter, the form of the sternum and number of the fingers, prove that it was not a bird. These characters place it among reptiles, but it had also a modification of the anterior extremities in the form of wings, which are not possessed by any existing or any other fossil members of the class, the so-called wings of the dragon being merely membranous expansions from the sides of the body supported by the ribs. The form of the wings is also remarkable and unique; in birds the fingers are very little separated, and serve as a basis for the plumes; in bats the flying membrane is stretched upon the four elongated fingers, the thumb remaining rudimentary; but in the pterodactyl the external finger alone is greatly developed and supports the flying membrane, the other four having the usual short dimensions; the membrane extended probably from the long finger along the sides of the body to the hind limbs and beyond, including the tail. About 20 species are described, varying in alar extent from a few inches to four or five yards; they probably flew and crept about in the manner of bats; the form of the teeth and strength of the jaws indicate a carnivorous animal, but of feeble powers; the smaller species must have been insectivorous, and the largest may have seized fish or small reptiles of their own or other genera. The great size of the eyes indicates nocturnal habits; the posterior limbs were so far developed that they could doubtless assume an erect position like birds, and perch on trees; the claws of the fore and hind feet would also enable them to climb along the rocks; the body was probably scaly, as in lizards. From the weakness of the scapular arch some have doubted the power of active flight in the pterodactyl, believing that the wing membranes could only support it in the air when leaping, in a little more perfect manner than in the dragons; but it must be remembered that the atmosphere of the secondary geological age was much more dense than the present, requiring proportionally less muscular force for aerial locomotion. The most anciently known species is the *P. longi-*

rostris (Oken), about the size of a woodcock, with a length of 10 in. and an alar extent of 21 in.; the teeth were $\frac{1}{4}$ on each side. The *P. brevisrostris* (Cuv.) had a shorter muzzle, the head resembling more that of a goose just hatched than of a reptile; the teeth were very small, $\frac{1}{8}$; the total length was less than 3 in., and there were only four posterior toes. Other species were less than 2 in. long, while on the contrary the *P. ornis* (Giebel) of the wealden was 2 ft. in length; in the chalk of Maidstone, England, Mr. Bowerbank detected bones of a species which he named *P. giganteus*, 6 to 7 ft. in alar extent; the *P. Cuvieri* (Bowerb.) is believed to have spread $16\frac{1}{2}$ ft. In 1871 Prof. Marsh found in the upper cretaceous rocks of western Kansas a species with an expanse of wing of 20 ft., which he named *P. Owenii*. Since 1869 Prof. Marsh has discovered the remains of three different species in the same regions.—The genus *rhamphorhynchus* (H. von Meyer) or *ornithocephalus* (Sömm.) was separated for a few species of the Jurassic age, having the anterior portion of the jaws without teeth, and probably with a horny beak; the scapula and coracoid were consolidated together, and the tail long and stiff, with about 30 vertebræ; there were four joints in the wing finger; the largest species was about 18 in. long. The genus *ornithopterus* (H. von Meyer) had only two joints in the wing finger.

PTEROPODS. See MOLLUSCA.

PTOLEMAIS. See ACRE.

PTOLEMY (Gr. Πτολεμαῖος), the name of 13 Greek kings of Egypt, of whom the first three were the most important, and are treated in separate articles. Ptolemy IV., Philopator (222–205 B. C.), son of Ptolemy III., was mainly distinguished for cruelty and debauchery. The reign of Ptolemy V., Epiphanes, his son (205–181), was marked by the rapid decline of the Egyptian monarchy. His son Ptolemy VI., Philometor (181–146), by Cleopatra, daughter of Antiochus the Great of Syria, was aided in his wars with Syria, where he was some time a captive, by the Romans. Ptolemy VII., Physcon (the Fat, his usual cognomen, but called by himself Euergetes II., 146–117), brother of the last, with whom he reigned jointly for a time, and whose son he murdered, was driven to Cyprus by a rebellion of the Alexandrians on account of his cruelty, and afterward restored. He married his sister Cleopatra II., and afterward his niece Cleopatra III., and was a patron of letters and himself an author. Ptolemy VIII., Lathyrus, ruled in conjunction with his mother Cleopatra III. at intervals from 117 to 81, and married his sister Cleopatra IV. During his reign Thebes, having revolted, was destroyed. Ptolemy IX. (Alexander I.), brother of the last, ruled for a while in conjunction with his mother. His wife was his sister Berenice III. Ptolemy X. (Alexander II.), step-son and husband of Berenice III., whom in 81 he put to death, was himself expelled and slain after a reign of 19 days. With him

expired the legitimate line of the Ptolemies. Ptolemy XI., Nothus or the Bastard, also called Auletes or the Flute Player (80-51), an illegitimate son of Lathyrus, was one of the worst of the Ptolemies, and his reign was marked by complications with the Romans, whom he courted. He was expelled in 58, and restored in 55 by A. Gabinus, proconsul in Syria, for a bribe of 10,000 talents. Ptolemy XII. (51-48), his son, ruled in conjunction with his sister Cleopatra VI., whom he expelled in 49; for this the Romans made war, and he was lost in attempting to escape. Ptolemy XIII., Puer, younger brother of the last, married his sister, widow of Ptolemy XII., and was poisoned by her in 48. With him closes the line, although some reckon Cæsarion, the son of Cleopatra by Cæsar, as Ptolemy XIV. (See CLEOPATRA.)

PTOLEMY I., surnamed **SOTER**, son of Lagus, and founder of the Græco-Egyptian dynasty, born near the court of Philip of Macedon in 367 B. C., died in Alexandria in 283. His mother Arsinoë had been a concubine of Philip, and many therefore supposed him to be his son. He was one of the principal generals of Alexander the Great in his Asiatic campaigns. After the death of Alexander in 323, he became governor of Egypt during the nominal reigns of Philip Arrhidæus and Alexander IV., and the regency of Perdiccas. One of his first acts was to put to death Cleomenes, who as receiver general of tributes had amassed an enormous fortune, and was a partisan of Perdiccas. In 322 he annexed the city and province of Cyrene. To oppose Perdiccas, he leagued in 321 with Antigonus, Antipater, and Craterus. Perdiccas invaded Egypt, but Ptolemy defeated him and prevented him from crossing the Nile. Subsequently, when Perdiccas was murdered by his own soldiers, Ptolemy sent wine and provisions to the invading army, and so won them that they offered him the regency, which he declined. In 320 he seized upon Phœnicia and Cœle-Syria, and it was probably during this expedition that he took possession of Jerusalem without opposition by attacking it on the sabbath. To resist Antigonus, he formed a coalition in 316 with Seleucus, Cassander, and Lysimachus; and after a struggle of four years, during which he lost Phœnicia, peace was concluded (311). In 310 Ptolemy renewed hostilities under the pretext that Antigonus had violated the treaty by keeping his garrisons in the Greek cities of Asia Minor and the adjacent islands, and in the long war which followed he lost Cyprus by his defeat in the sea fight near Salamis in 306. Antigonus assumed the title of king, and Ptolemy followed his example. Demetrius, the son of Antigonus and conqueror of Salamis, now invaded Egypt, but, baffled at the banks of the Nile, turned his arms against Rhodes, which had refused to join in the attack. Ptolemy enabled it to hold out by furnishing troops and provisions, and out of gratitude the Rhodians gave him the title of saviour (Soter). The death of Antigonus at

the battle of Ipsus in 301 terminated the war, and added Syria and Palestine to Ptolemy's dominions; and in 295 Cyprus was recovered. In 287 he was in league with Seleucus and Lysimachus against Demetrius, but the rest of his reign was peaceful. He made Memphis his capital, took measures to promote the happiness of his Egyptian subjects, revived their ancient religious and political constitution, and restored to the priestly caste some of its former privileges. He showed equal toleration to the Jews and the Greeks, and great numbers of both, among them scholars of the greatest renown, were attracted to Alexandria. He laid the foundation of literary institutions, the most celebrated of which were a library and a museum, a kind of university whose professors and teachers were supported at the public expense. Ptolemy wrote a history of the wars of Alexander. He wished his youngest son Ptolemy Philadelphus, the offspring of his favorite wife Berenice, to succeed him, to the exclusion of his elder son by his former wife Eurydice, and effected his purpose by abdicating in his favor in 285, continuing however to exercise sovereignty until his death.

PTOLEMY II., surnamed **PHILADELPHUS**, king of Egypt, youngest son of the preceding by Berenice, born in the island of Cos in 309 B. C., died in Alexandria in 247. He was carefully educated, and was thoroughly imbued with his father's policy. He cleared Upper Egypt of robbers, penetrated Ethiopia, establishing traffic with the tribes, and opened southern Africa to the Alexandrian merchants. To command the Red sea, he founded Arsinoë (near Suez), and connected it with Alexandria by restoring and completing the canal begun by Necho. He constructed the ports of Myos-Hormos and Berenice, and connected the latter with Coptos on the Nile by a road 258 m. long across the desert. The museum founded by his father was improved by the addition of botanical and zoological gardens, works of art were collected from Greece, and large additions were made to the library. (See ALEXANDRIAN LIBRARY.) He spent vast sums on public works, built the celebrated lighthouse on the island of Pharos, and erected a magnificent royal mausoleum, to which he removed the remains of Alexander the Great from Memphis. The most distinguished poets, philosophers, mathematicians, and astronomers resided at his capital. For the use of the Alexandrian Jews, the Septuagint version of the Hebrew Scriptures is said to have been made by his command. His reign was disturbed by the revolt of his half brother Magas, viceroy of Cyrene, who succeeded in maintaining his independence; and by a contest with Syria for the possession of Phœnicia and Cœle-Syria, which was kept up at intervals till near the close of his life, when these provinces at last remained in his possession. He took part several times in the affairs of Greece, maintaining an unfriendly attitude toward Macedon, and established relations of

amity with the rising republic of Rome. He founded a gymnasium at Athens, and planted numerous colonies in various parts of his foreign dominions, which comprised Phœnicia, Cœle-Syria, Palestine, Cyprus, the Cyclades, and portions of southern Asia Minor, Ethiopia, Arabia, and Libya. The effeminacy of his court increasing with the wealth of the country, he came at length to lead the indolent life of a refined voluptuary. Repudiating his first wife, Arsinoë, daughter of Lysimachus, he married his own sister Arsinoë, widow of Lysimachus, which the Egyptian law allowed, but she brought him no children. Another stain on his memory is the execution of two of his brothers, for which his surname, which he himself had assumed to signalize his attachment to his sister, became a subject of derision.

PTOLEMY III., surnamed **EVERGETES**, eldest son and successor of the preceding, by Arsinoë, daughter of Lysimachus, died in 222 B. C. On coming to the throne he found in the public treasury an immense amount of money, and at his command a vast army and navy. His warlike ardor was roused by the ill treatment and subsequent murder of his sister Berenice, wife of Antiochus Theos, king of Syria. With a large army he ravaged Syria and its eastern provinces, advancing as far as Susa, and, without establishing his authority in any new possessions, brought back immense booty in gold and silver, and the Egyptian idols which Cambyses had carried off to Persia. For this the Egyptians called him *Euergetes* (benefactor). In right of his wife Berenice, daughter of Magas, Cyrene was united to his dominions, and he made large acquisitions of territory in Arabia and Abyssinia. He inherited the religious liberality and love of learning of his progenitors, and was like them a proficient in letters.

PTOLEMY, Claudius, a Helleno-Egyptian mathematician, astronomer, and geographer, said to have been born in Pelusium, flourished at Alexandria in the 2d century A. D. Scarcely any particulars of his life are known. His *Μεγάλη Σύνταξις της Ἀστρονομίας*, or "Great Astronomical Construction," contains nearly all that is known of the astronomical observations and theories of the ancients, and is generally cited under the Latin titles *Syntaxis Mathematica* and *Constructio Mathematica*. The most important part of this work is a catalogue of stars, deduced from that constructed by Hipparchus. (See **PRECESSION**.) The *Syntaxis* treats of the relations of the earth and heavens; the effect of position upon the earth; the theory of the sun and moon, without which that of the stars cannot be undertaken; the sphere of the fixed stars; and the determination of the planetary orbits. He places the earth in the centre of the universe, and the Ptolemaic system, based on the theories of Hipparchus, was universally received till the time of Copernicus. During all that interval the history of astronomy presents scarcely anything more than comments on

Ptolemy's writings. But for the Arabians the *Syntaxis* would probably have perished. It was translated by them in the reign of the caliph Al-Mamoun, son of Haroun al-Rashid (about 827), and handed down under the title of *Almagest*. Translations from the Arabic were made into Latin, but the Greek text was subsequently also discovered in Byzantine manuscripts. Ptolemy left a copious account of the manner in which Hipparchus established his theories, and in most of the branches of the subject gave additional exactness to what that astronomer had done. He computed, notwithstanding the fundamental errors and the inaccuracies of his system, the eclipses of the next six centuries; determined the planetary orbits; and is commonly said to have discovered the moon's second inequality or evection, though it is probable that Hipparchus really detected this inequality. Three observations cited by Ptolemy in support of his theory were borrowed from Hipparchus, and the nature of one of them suggests that they were taken from a great mass of observations, though Ptolemy himself says nothing to that effect. The astronomer who took a predecessor's star catalogue, and adding a constant correction to each star published it as the result of his own observations, would have left unnoticed all lunar observations by Hipparchus not absolutely necessary to establish his own theory. As a geometer Ptolemy has been ranked as certainly the fourth among the ancients, after Euclid, Apollonius, and Archimedes. He caused light to pass through media of unequal density, and thus discovered refraction, and he is said to have first recognized the alteration of the apparent position of a heavenly body which is due to this cause; but here again it is probable that Hipparchus anticipated him. Ptolemy wrote a universal geography, which continued to be the standard text book till the 16th century. He was the first to use the terms latitude and longitude, by which he laid down the position of each country and town. He proved the earth to be a globe, and calculated its inhabited parts to extend from the meridian of Thina, lon. 119° 30' E. of Alexandria, to the meridian of the Islands of the Blessed, 60° 30' W.; and from the parallel of Meroë, about lat. 16° 30' N., to that of Thule (Iceland or the Shetland islands), 63° N. The maps of this geography have been preserved with it. After him no one attempted for many centuries to reform geography except in the improvement of details. He was distinguished also as a musician, and wrote treatises on music, mechanics, chronology, and astrology; but probably most of these works were mere compilations. The best edition of the *Almagest* is by Halma (Greek text with French translation, 2 vols. 4to, Paris, 1813-'16).

PUBERTY, the period of youth characterized by the acquirement of functional power in the reproductive apparatus of the sexes; its ac-

tivity, however, cannot be called into exercise until the growth of the individual is completed, on penalty of premature and permanent exhaustion of the vital powers, and the development of any latent disposition to disease. That puberty is not the period of completed growth is shown by the increase in stature after its attainment, the subsequent complete ossification and consolidation of the extremities of the spinous and transverse processes of the vertebræ, and the consolidation of the pelvic, sacral, and coccygeal vertebræ, sternal pieces, and epiphyses of the ribs, scapula, clavicle, and bones of the extremities. In the human male puberty is established between the 14th and 16th years; besides the increased sexual and muscular development, the beard makes its appearance, the larynx enlarges, giving a lower, harsher, and stronger tone to the voice, and the thoughts, desires, and actions have a more manly character. In the female this period is arrived at between the 13th and 16th years in temperate climates, and somewhat earlier in the tropics and in the midst of the luxury and excitements of city life; there is a similar development in the reproductive system, usually coincident with the appearance of the catamenia and mammary enlargement, and a deposition of fat over the whole surface of the body. In the male there is at this time no special tendency to disease, nor in the healthy female; but, as a consequence of the defective physical training of most female youth, disorders of the menstrual function are very apt to occur, with numerous functional, nervous, and even organic complications; in persons of naturally weak constitutions, of both sexes, and in those enfeebled by premature exercise of the mental, physical, or generative powers, the tuberculous diathesis is frequently developed soon after puberty.

PUBLICOLA, Publius Valerius, a Roman law-giver of the semi-historical period of the foundation of the republic. He is said to have been present when Lucretia stabbed herself, and to have borne a prominent part in the expulsion of the Tarquins. After the compulsory resignation of Collatinus he was elected consul in his place (about 509 B. C.). In the war between the Tarquins and Veientes and the Romans, he gained a victory over the former. Returning to Rome, he began building a house on the Velian hill overlooking the forum, which excited a popular fear that he was seeking to raise himself to royal power. Valerius therefore ordered the building to be demolished, and his lictors when they appeared before the people to lower their fasces; whence he received the surname of Publicola or Poplicola, "the people's friend." He now brought forward laws for the establishment of the republic, one of which declared that whoever attempted to make himself king might be killed by any one; another, that plebeians condemned by a magistrate might appeal to the people. He was afterward thrice elected

consul; and the expedition of Porsena is placed during his time of office. With T. Lucretius Tricipitinus, his colleague, he routed the Sabines and returned to Rome in triumph.

PUBLIUS SYRUS, a Latin comic poet, who flourished at Rome at the time of Caesar's death (44 B. C.). He was a native of Syria, and was brought to Rome as a slave; but his master had him instructed and gave him his freedom. He improved the mimic art, and it is said by St. Jerome that a collection of moral sentences from the farces of Publius was a school book at Rome. A collection of this kind, comprising upward of 1,000 lines, each forming an apophthegm, extant under the title of *Publii Syri Sententiæ*, is in reality a compilation from various sources.

PÜCCOON, an aboriginal name applied to several plants with a yellow or reddish juice, but quite unlike in other properties. In the south, the bloodroot (*sanguinaria Canadensis*) is called puccoon. (See BLOODROOT.) In some parts of the west the name is applied to two species of *lithospermum*, of the borage family, both yielding a red dye; *L. hirtum* being the hairy, and *L. canescens* the hoary puccoon. The name is perhaps more generally used to designate *hydrastis Canadensis* than either of the foregoing, which is called, besides yellow puccoon, golden-seal, yellow-root, orange-root, Indian paint, &c. The genus *hydrastis* (Gr. ὕδωρ, water, and δράν, to act) belongs to the crowfoot family, or *rannunculaceæ*. It has a thick, knotted, yellow rootstock, from which rise a single radical leaf and a low, simple, hairy stem, bearing two leaves near the summit, and terminated by a single apetalous greenish white flower; the three petal-like sepals fall away when the flower opens, leaving the numerous stamens, and the cluster of 12 or more pistils, which in fruit become berry-like, and, being bright crimson, the cluster has the appearance of a raspberry. There is but one species, which is found from New York westward and southward, and is nowhere very common. It was used by the aborigines as a stimulant application to ulcers, and also as a dye; it is among the many reputed cancer cures. It is a tonic, and is regarded by some as having especial action on the liver and kidneys. In the western states it is used as an antiperiodic, as a substitute for quinine; the dose in powder is 30 to 60 grains. The so-called hydrastin of the eclectics, precipitated from a concentrated infusion by muriatic acid, is used in doses of three to five grains; it consists mostly of berberine.

PÜCKLER-MUSKAU, Hermann Ludwig Heinrich von, prince, a German author, born at Muskau, Lusatia, Oct. 30, 1785, died at Branitz, near Kottbus, Feb. 4, 1871. He studied in Leipsic, served in various armies, and was made prince by the king of Prussia in 1822. He laid out magnificent parks at Muskau and Branitz, but in 1845 sold the former domain. His private life was marked by eccentric habits. Among his principal works, which chiefly de-

scribe his extensive travels in Europe and the East, and are remarkable for racy delineations both of aristocratic and semi-civilized life, are: *Briefe eines Verstorbenen* (4 vols., 1830-'31; English translation by Mrs. Sarah Austin, "The Travels of a German Prince in England," 3 vols., 1832); *Andeutungen über Landschaftsgärtnerei* (1834); *Tutti Frutti* (5 vols., 1834; English translation by Edmund Spencer, 1834); *Semilasso's vorletzter Weltgang* (3 vols., 1835); *Semilasso in Afrika* (5 vols., 1836); *Südöstlicher Bildersaal* (3 vols., 1840); *Aus Mehemet Ali's Reich* (3 vols., 1844); and *Die Rückkehr* (3 vols., 1846-'48; English translation, "Mehemet Ali and Egypt," 3 vols., 1848). Ludmilla Assing has published *Fürst Pückler Muskau, sein Leben und Nachlass* (4 vols., 1873-'4).

PUDDLING. See IRON MANUFACTURE, vol. ix., p. 399.

PUEBLA. I. A S. E. state of the republic of Mexico, bounded N. and E. by Vera Cruz, S. by Oajaca, S. W. by Guerrero, and W. by Mexico, Tlascala, and Hidalgo; area, 9,598 sq. m.; pop. in 1869, 697,788. It is intersected from N. W. to S. E. by the Cordillera of Anáhuac, from which flow many small streams, but there are no large rivers. The drainage belongs partly to the gulf of Mexico and partly to the Pacific. The general elevation of the surface is about 6,000 ft., and a large part of the soil is fertile. The most valuable mineral productions are silver, marble, and alabaster. Abundant crops of grain, fruit, sugar, and cotton are produced; and iron, steel, glass, soap, and earthenware are manufactured. Many remarkable remains of ancient Mexican civilization are found in this state. II. A city (LA PUEBLA DE LOS ÁNGELES), capital of the state, 7,000 ft. above the sea, in lat. 19° 5' N., lon. 98° W., 76 m. E. S. E. of Mexico; pop. in 1869, 75,500. The streets are laid out generally at right angles to each other, and are broad and well paved. There are many fine squares; fronting the Plaza Mayor are the cathedral, the governor's palace, and the exchange. Puebla is the sacred city of Mexico, and contains more than 60 churches, 13 nunneries, 9 monasteries, 21 collegiate houses or higher theological schools, and many academies, charity schools, hospitals, and other benevolent institutions. Many of the churches and convents are rich in gold and silver ornaments, paintings, and statues, but some of them were injured by the French during the siege in 1863. The city is well supplied with water by a small stream on its E. side. The country around it is very fertile, it being easily irrigated by streams from the mountains. The climate is particularly mild and agreeable. Within sight of the city are the volcanic peaks of Popocatepetl, distant about 25 m. W. by S.; Iztaccihuatl, 30 m. W. N. W.; Malinche, 20 m. N. E.; and Orizaba, 60 m. E. Puebla is connected with the railway from Vera Cruz to Mexico by a branch road to Apizaco, 29 m. long, and a road is now building (1875) to connect it directly

with Vera Cruz.—Puebla was founded after the reduction of Mexico by the Spaniards, who built it six miles from Cholula, the sacred city of the Mexicans. It is noted for its protracted defence against the French under Gen. Forey in 1863, when it withstood a siege of two months. It was surrendered by Gen. Ortega on May 17, after the destruction of many of its buildings by bombardment, and the French made a triumphal entry on the 19th.

PUEBLO, a S. E. county of Colorado, intersected by the Arkansas river; area, about 2,200 sq. m.; pop. in 1870, 2,265. The tributaries of the Arkansas form fertile valleys, with intervening mesas or table lands, which afford excellent pasturage. The greater portion of the county is easily irrigated. The Denver and Rio Grande railroad traverses it. The chief productions in 1870 were 24,451 bushels of wheat, 99,390 of Indian corn, 39,822 of oats, 3,353 of peas and beans, 6,000 lbs. of wool, 14,963 of butter, and 1,366 tons of hay. There were 555 horses, 4,269 milch cows, 6,162 other cattle, 2,166 sheep, and 2,066 swine. Capital, Pueblo.

PUEBLO INDIANS, a general name applied by the Spaniards, and subsequently by Americans, to several tribes of semi-civilized Indians found by the former early in the 16th century in what is now New Mexico, who lived in permanent villages (*pueblos*). Alvar Nuñez (Cabeça de Vaca) passed through their country between 1529 and 1538; Friar Marco de Niza visited it in 1539, and Coronado in 1540. They were finally subdued by the Spaniards, who occupied the country in 1586. They were then as advanced as they now are, raising grain, vegetables, and cotton, which they spun and wove, and manufacturing pottery. Their houses are sometimes built of stone, laid in mortar made of mud, but more generally of sun-dried brick or adobe. These buildings are generally large, of several stories, and contain many families. In some of the pueblos the whole community, amounting to from 300 to 700 souls, are domiciled in one of these huge structures. The houses are sometimes in the form of a hollow square; at other times they are on the brow of a high bluff or mountain terrace, difficult of approach. The first or lower story is invariably without openings, entrance to the house being effected by ladders. Each upper story recedes a few feet from that below it, leaving a terrace or walk around or along the whole extent of the structure, from which ladders lead to those above. The upper stories have doors and windows, but no stairways. In most instances a single family occupies one apartment, and as its number increases another apartment is added when there is sufficient space, or it is built above and reached by a ladder. This mode was practised by these Indians three centuries ago. In every village there is at least one room large enough to contain several hundred persons, in which they hold their councils and have their dances.

These Indians constituted several distinct tribes with different languages. Some of them are now extinct; those still existing are: 1, the Zuñis, inhabiting Zuñi; 2, the Toltos, inhabiting Taos, with whom some unite the Picuries and the people of Sandia and Isleta; 3, the Tegnás in San Juan, Santa Clara, Nambé, San Ildefonso, Pojuaque, and Tesuque; 4, the Queres in Cochiti, San Domingo, San Felipe, Santa Aña, Zia, Laguna, and Acoma; and 5, the Jemes, occupying a town of the same name. The population of these 19 pueblos, and some now abandoned, toward the close of the last century was given at 10,000 or 11,000. Under the Spanish government schools were maintained and religious instruction given by Franciscan and other Catholic missionaries, who began their labors before 1600, and still continue them. They were protected from hostile tribes and oppression, and supplied with cattle and sheep; but under Mexican rule they were deprived of this support, and have declined till they now number only about 7,000. They were recognized as citizens under Mexican rule, but since New Mexico became a part of the United States the matter has been left in doubt. In 1857 Chief Justice Slough decided that the Pueblo Indians were under the treaty citizens of the United States. An act of congress passed Dec. 22, 1858, had confirmed old Spanish grants to the Pueblos. Their status as tribes has not, however, been recognized by any treaties; and though judicially declared to be citizens, the laws of New Mexico deprive them of the suffrage. They retain their own government, each village having an elected governor, and a court consisting of three old men; but executions for witchcraft have led to interference by the territorial authorities. A Baptist mission established a few years ago at Laguna led to dissensions and punishments there, which again called for interference. Under the division of tribes among the different denominations, the Pueblos, though Catholics, were assigned to the Christians, and, on their non-action, to the Presbyterians. This led to a protest from the governors of 15 pueblos at Santa Fé, Aug. 16, 1872, and to an appeal to the government made through the Catholic commissioner in 1874. Under the new agency eight schools are supported, which number 298 pupils. The total wealth of the Pueblo Indians in 1873 was given at \$535,750.

PUERPERAL CONVULSIONS, or *Puerperal Eclampsia* (Lat. *puer*, child, and *parere*, to bring forth), a dangerous disease occurring during the puerperal or lying-in period of women, either before, during, or after delivery. It has been the source of much discussion and disagreement, and although recent advances in physiological chemistry have shed much light on the causes of the disease, many points remain in dispute. It has been asserted by Dr. Karl Braun of Vienna that it is commonly the result of uræmic poisoning, and is produced mostly by carbonate of ammonia in the blood,

arising from decomposition of urea; but although it is conceded that uræmic poisoning is a frequent cause of puerperal convulsions, the ammonia theory, which originated with Dr. Frerichs of Berlin, is not generally accepted, and many believe that a variety of causes other than urea in the blood are competent to produce convulsions by acting upon the highly developed nervous system of the puerperal woman. Even when the attacks are connected with organic or functional disease of the kidneys, and when the urine is albuminous, the presence of urea in the blood is not always made out; and in many marked cases of albuminuria during pregnancy convulsions do not occur. Constipation, retention of urine, extreme pain, and great mental distress may, it is contended, bring on in the puerperal state convulsions precisely similar in character to those produced by uræmia. According to Braun and Wiegner, more than half of all the cases occur during labor, but others consider the relative frequency during the three epochs to be in the order, pregnancy, labor, delivery. It is more likely to occur in first than in succeeding labors. The frequency of the disease, as indicated by statistics, is about one case in 350 labors. There are usually, but not always, premonitory symptoms. One of the most important and common of these is œdema or dropsy, especially of the ankles and feet, which is usually developed some weeks before the appearance of the first fit. When this symptom is present, an examination of the urine is almost sure to reveal by the ordinary tests of heat and nitric acid the presence of a large quantity of albumen; and there may generally be found, by the aid of the microscope, several tube casts, sometimes accompanied with blood corpuscles, or there may be evidence of a more advanced stage of Bright's disease. Pregnancy disposes toward this condition by reason of obstruction to the circulation from pressure of the gravid uterus. There are three objective premonitory symptoms which are also important: extremely acute headache, derangement of vision, and pain in the epigastrium. The headache is generally in the frontal region, at first intermittent, but gradually becoming continuous. Derangement of vision is a grave symptom; sometimes there is cloudiness or dimness, at others objects appear to change color; there is often double vision, or only half of an object may be seen; there are flashes of light, and sometimes the sight is suddenly lost. The convulsive seizure is characteristic, and to have witnessed it once will impress its prominent features upon the memory. After a few precursory symptoms the patient seems deeply absorbed and preoccupied; then her gaze becomes fixed and her whole body motionless. This is soon succeeded by twitchings of the eyelids and facial muscles. The eyeballs roll upward so that only the whites are seen. The contractions of the muscles from being spasmodic or clonic

become tonic, as it is called; that is, they become more persistent. The angles of the mouth are strongly drawn to one side, the muscles of the neck drawing the head in the same direction. After a few moments these parts will be drawn in the contrary direction. From the head the convulsive phenomena rapidly extend to other parts of the body. The extensor muscles of the trunk contract, producing the condition called *opisthotonos*, and the whole trunk becomes perfectly rigid. The neck swells, the jugular veins becoming prominent, and the carotid arteries beat violently. Contraction of the muscles of the larynx causes suspension of respiration, the capillary circulation becomes impeded, and the face assumes a livid hue. The tongue is often severely bitten between the convulsively closed jaws. In about half a minute these tonic convulsions are generally succeeded by those of a clonic character, and jerking movements of all the muscles succeed, the countenance becoming frightfully distorted. The pulse, strong and full at the commencement, is rapidly accelerated by the convulsions, but at the height of the paroxysm is very feeble. It is during the middle stage, that of tonic convulsions, that death is immediately imminent, when the respiration is suspended and the condition is that of profound asphyxia. When recovery from the attack takes place, the symptoms gradually abate; the convulsive movements become less violent and then less frequent; the respiration becomes more regular but stertorous, and the circulation more active; and the skin resumes its natural color. The patient does not immediately regain consciousness, but remains in a comatose condition, the duration of which depends upon the intensity of the paroxysm; sometimes only a few minutes elapse, at others several hours. But recovery from the tonic stage may not take place, or there may be a succession of fits with intervals so brief that consciousness is not recovered between them, and the patient dies in a state of coma. In case of recovery, on regaining sensibility a confused feeling with headache is complained of, and she has no recollection of what has taken place. Sometimes there is impairment of vision or of hearing, or both. As to the effects of these convulsions, they may, if occurring before the lying-in period, bring on premature labor and destroy the life of either the mother or the child, or both, or they may happily terminate in recovery. When the attack precedes delivery, it frequently happens that the birth of a child removes the conditions upon which the convulsions depend, and the patient is immediately relieved. After delivery the attack may be followed by dangerous hæmorrhage, from non-contraction of the uterus, due to exhausted nervous energy or to the impoverished state of the blood. In some cases the recovery is surprising, and it often takes place contrary to the predictions of the most experienced. The treatment is prophylactic or

preventive, and curative. The prophylactic treatment consists in eliminating the urea from the system when present, by the use of diuretics and purgatives, and in relieving excessive plethora by bloodletting, which may sometimes be freely employed with advantage.

PUERPERAL FEVER, or *Childbed Fever*, a disease which attacks lying-in women, generally attended by an inflammation of the peritoneum, or of the uterus and its appendages, of a dangerous character. The name puerperal fever was given by Strother in his work on fevers (1716). Hippocrates gives accounts of cases of death in lying-in women which resembled the puerperal fever of to-day, as do Celsus, Galen, Avicenna, and others down to near the 17th century. From observations extending through the last two centuries it has been generally believed that the disease often prevails epidemically. It has been observed that lying-in women, attended by physicians coming from cases of erysipelas, gangrene, or sloughing sores of any kind, or from making post-mortem dissections, are very liable, sometimes almost certain, to be attacked with puerperal fever. These facts have caused several good authorities to regard the disease as due to the absorption of septic matter by an abraded surface on the body of the patient. Denman, an English obstetrician, is said to have been the first to assert that puerperal fever is often propagated by the medical attendant; and this view of the subject has been recently more particularly examined, and, with others in regard to its propagation by septic contact, adopted in Germany. That absorption may occur, there must be a fresh wound or abraded surface; if granulations have taken place, absorption is prevented. Now fresh wounds exist in every parturient woman in consequence of laceration or abrasion during labor, and infection may take place by decomposition in the tissues of the patient, or it may have an external origin. The authorities who embrace these views do not therefore regard puerperal fever as contagious in the usual sense of the word, that is, spread by a specific contagion; but admit that it is manually transferable, while the septic matter may be brought from an external source in which puerperal fever is not present.—The virulence of cases which have been called puerperal fever has varied very greatly at different times and in the practice of different physicians, and the post-mortem appearances of the fatal cases have been unlike. Sometimes there would be found extensive lesions, not only in nearly all the pelvic viscera, but in other parts of the body. Sometimes there would be peritonitis alone, or with very few complications, and sometimes only the uterus would present much evidence of inflammation; and in some of the most rapidly fatal cases no evidence of established inflammation would be found. Moreover, the number of recoveries would be great in the practice of some physicians, and many of the cases would present symptoms indica-

ting little more than inflammation of the connective cellular tissue of the pelvic cavity. It will therefore be seen that the subject is one of the most difficult and perplexing which writers on obstetrics have to meet. No system of classification has been generally agreed upon, but several authorities, with the sanction of Sir James Y. Simpson and others, embrace within the term puerperal fever all those lesions of pelvic organs and tissues which in the puerperal state, under favorable circumstances, are liable to engender and propagate septic poison. But it is asserted by many high authorities that there is a form of the disease which is characterized from the first by symptoms indicating the operation of a virulent poison, and which has received the name of malignant puerperal fever, or puerperal typhus. This may be regarded as the true epidemic puerperal fever. Those who maintain these views also believe in the contagiousness of the disease, and in their classification they separate epidemic puerperal fever from such affections as are specially named puerperal metritis, puerperal peritonitis, puerperal phlebitis, puerperal pelvic cellulitis, and puerperal septicæmia and pyæmia. The symptoms of epidemic or malignant puerperal fever usually commence with a chill between the first and third days after delivery, rarely being deferred to the fifth day, although sometimes to the eighth or ninth; but this is not one of the most important symptoms, for it is sometimes so slight as not to attract attention. In some cases, however, it is very severe and lasts 30 or 40 minutes or longer, and during the chill the pulse is small and quick; afterward it becomes fuller but more compressible, ranging from 110 to 150. There is more or less delirium, and vomiting is quite common. Sometimes these symptoms are intensified, and the patient succumbs to the attack in 24 or 48 hours. In cases of the epidemic disease post-mortem examination will sometimes reveal not many pathological changes, but sometimes they are quite extensive and similar to those in septicæmia and pyæmia. In cases of puerperal peritonitis, there may be nothing found except indications of inflammation of the peritoneum; but in cases of septicæmia and pyæmia there will usually be found abscesses in different parts of the body. The uterus will be found cedematous, and its lymphatics are usually distended with purulent contents, which are often traced to ulcers on the neck of the womb. There are often dilatations in the lymphatics as large as a hazel nut, filled with pus; and there are frequently abscesses in the body of the uterus causing perforations into the peritoneal cavity. The cellular connective tissue becomes inflamed and filled with serum, and often pelvic peritonitis follows this, and may extend to the general abdominal cavity, its contents becoming more or less adherent to each other from the formation of false membrane. Changes occur in other cavities besides that of the peritoneum; extravasations of blood

are often found beneath the lining membrane of the heart and the mucous membrane of the intestines. There is also often found pericarditis and inflammation of the joints, most frequently in the shoulder and knee, the pus undermining the surrounding parts, often to a great extent. Embolism of the blood vessels is common, especially in the lungs, the thrombi which form in these organs breaking up and passing on into the circulation. Pneumonia is frequent, with a great tendency to gangrene, caused by the presence of putrid emboli. The spleen is frequently enlarged, of a pulpy, greasy consistence and of a chocolate color; and the liver presents marks of fatty infiltration, embolism, and disintegration of liver cells.—The treatment in all these puerperal diseases depends upon the extent and intensity of the attack, and upon the organs involved, and consists to a great degree in prophylactic measures, such as cleanliness, including the prevention of the reabsorption of septic matter, and a bland but not innutritious diet. The medical attendant should exercise the most extreme care not to approach the lying-in chamber after attending cases of erysipelas or scarlet fever, or any other contagious disease. If he has recently attended a post-mortem dissection, he should bathe his person, use carbolic or salicylic acid gargles, and change his entire clothing.—See “Clinical Lectures on Diseases of Women,” by Sir James Y. Simpson, M. D. (Edinburgh, 1871); “A System of Midwifery,” by William Leishman, M. D. (Glasgow, 1873); “On the Nature, Signs, and Treatment of Childbed Fever,” by Charles D. Meigs, M. D. (Philadelphia, 1872); “The Puerperal Diseases,” by Fordyce Barker, M. D. (New York, 1874); “Erysipelas and Childbed Fever,” by Thomas C. Minor, M. D. (Cincinnati, 1874); and “A Manual of Midwifery,” by Dr. Karl Schroeder (New York, 1875).

PUERPERAL MANIA, a form of mental derangement which attacks women during the lying-in period. It is to be distinguished from the melancholia which occurs at the same period, although some authors treat both affections under one head, either that of puerperal mania or puerperal insanity. It is also to be distinguished from the insanity of pregnancy and the insanity of lactation, affections which are liable to occur in the earlier stages of pregnancy, or during lactation after the puerperal period has passed; and it is also distinct from the delirium of labor. The insanity of pregnancy, which generally occurs between the third and seventh months, may be caused by derangement of some of the bodily functions, usually associated with an anæmic condition, and, according to Esquirol, dependent in more than one third of the number of cases upon hereditary predisposition. The insanity of lactation generally occurs after the sixth month of that period, and therefore its principal cause, weakness from the exhaustion of nursing, is appa-

rent. The delirium of labor is caused by the over-excited or erethistic condition of the brain in consequence of the intensity of the pains of labor. It is of much rarer occurrence since the use of anesthetics in labor than formerly. Puerperal mania generally comes on during the first two weeks after confinement, while melancholia is rarely developed until the latter part of the month. Among other prominent premonitory symptoms are sleeplessness, loquaciousness, and aversion toward friends; and a short period before the attack there are often movements of the eyelids and facial muscles. At the moment of attack the facial expression is often peculiar, the features becoming drawn and pallid, with an expression of fright mingled more or less with that of rage. The patient then becomes boisterous, stares wildly and makes rapid gestures, clutches at things and persons near her, throws off her covering, and attempts to jump out of bed; and her language will often be so profane as to mortify her friends. The skin is cold, pallid, and clammy, and the pulse is small, quick, and irritable. There is great muscular weakness, which however sometimes alternates with great spasmodic strength.—Among the predisposing causes heredity is the most frequent, and it is said to be generally traceable to the female side of the family. The pathological condition of the brain is therefore similar to that of insanity in general, but this cannot always be demonstrated by microscopical examination. The principal exciting cause is mental emotion, and it has been observed that those who possess the most sensitive organizations and have been particularly the victims of treachery are much more likely than others to be attacked. Formerly it was frequently held that the disease was of inflammatory origin, being a modification of phrenitis; but the opinion advanced by Gooch, that "it is not a disease of congestion or inflammation," has been sustained by modern experience. Dr. Ferriar believes that the loss of reason is often principally due to some interference with the establishment of lactation. Convulsions which occur after labor are frequently followed by mania. It seems to be well established that there is an essential connection between puerperal mania and albuminuria; but the indications of the presence of albumen are less persistent than in convulsions.—Bleeding, which was once a common practice, is now regarded as injurious in all but a very few exceptional cases, as the disease is nearly always associated with an anæmic condition of the blood and a state of nervous exhaustion. The best therapeutic agent for relieving the cerebral excitement is perhaps the hydrate of chloral, and it is said to have a much better effect than pure chloroform. The most important remedial treatment, however, is the use of nutritious food to restore the exhausted nervous energy by reëstablishing the organic functions. Ferruginous tonics may also be given with advantage.

PUERTO BELLO. See PORTO BELLO.

PUERTO CABALLOS. See CORTES.

PUERTO CABELLO, a seaport town of Venezuela, in the province of Carabobo, on Trista bay, 70 m. W. of Carácas; pop. about 8,000. The town is principally on an island, which is connected with the mainland by a bridge. The climate is hot and unhealthy, but the harbor being fine, the place is the seat of a considerable trade. During the year ending Sept. 30, 1873, the total value of the imports was \$3,691,237; of the exports, \$5,118,788; entrances, 205 vessels, of an aggregate tonnage of 103,476, of which 50 were German, 38 English, 32 Dutch, 27 Venezuelan, 19 Spanish, 13 French, 12 Danish, 10 American, 2 Austrian, and 2 Italian. The principal exports are cotton, coffee, cacao, indigo, sugar, cocoanuts, hides, lumber, and cabinet and dye woods. Of 20,011,801 lbs. of coffee exported in 1873, 6,212,890 came to the United States.

PUERTO LA MAR. See COBIJA.

PUERTO PLATA, or **Porto Plata**, a seaport town of Santo Domingo, on the N. coast, 100 m. N. N. W. of Santo Domingo city; pop. about 3,000. It lies on the slope of a mountain at the foot of a crescent-shaped bay. The harbor has good anchorage, but shallows rapidly near the shore, and ships are loaded from lighters. The trade, principally in tobacco, is in the hands of foreign merchants, mostly Germans. In 1873, 201 vessels, of 12,191 tons, entered the port; of these 75 were English, 37 Spanish, 34 German, and 20 American. The total value of the imports in 1873 was \$871,116; of the exports, \$1,093,753.—Puerto Plata is said to have been planned by Columbus on his first voyage. In the beginning of the 16th century it was largely resorted to by Spanish vessels. It has been destroyed several times, the last time by the Spaniards when they evacuated the island in 1865.

PUERTO PRINCIPE, *Santa Maria de*, a city of Cuba, capital of the Central department, about midway between the N. and S. coasts, 305 m. E. S. E. of Havana, and 45 m. W. S. W. of Nuevas, its port, with which it is connected by railway; pop. about 30,000. It lies between two small streams, the Tinima and the Jaticbonico, in a rich agricultural district, the chief products of which are sugar and tobacco. The climate is hot, moist, and unhealthy. The city is irregularly built. Its chief buildings are several churches and monasteries, a hospital, and two theatres. Its trade is inconsiderable compared with its population. Puerto Principe was formerly the seat of the supreme court of all the Spanish colonies in America. It has been threatened several times during the present war by the Cuban patriots, and two or three battles have taken place in its vicinity.

PUFENDORF (often spelled **PUFFENDORF** by English writers), **Samuel**, a German jurist and publicist, born near Chemnitz, Saxony, Jan. 8, 1632, died in Berlin, Oct. 26, 1694. He was educated at Grimma, studied theology at the uni-

versity of Leipsic, and in 1656 went to Jena to devote himself to mathematics and philosophy under Erhard Weigel, at the same time applying himself to the law of nature. On quitting Jena he became tutor to the son of the Swedish ambassador at Copenhagen, and while there prepared a work on general law, in which the principles of Grotius, Hobbes, and other jurists were combined with observations of his own. This was published in Holland in 1660 under the title of *Elementa Jurisprudentiæ Universalis*. It was dedicated to the elector palatine, Charles Louis, who in 1661 founded at Heidelberg a professorship of the law of nature and of nations, and placed Pufendorf in the chair. His lectures were very popular, and the university recovered during his residence much of its ancient prestige. In his *Severini a Monzambano, De Statu Imperii Germanici* (Geneva, 1667) he showed that the Germanic system was an incongruous assemblage of discordant parts, and the parent of many social and political abuses, and suggested practical remedies. The work was translated into the chief languages of Europe, but excited much hostile criticism in Germany, particularly in Austria, where it was ordered to be burned by the hangman. Pufendorf defended the work without acknowledging the authorship, but found his position so uncomfortable, in consequence of the acrimonious controversy with German publicists, that in 1670 he accepted from Charles XI. of Sweden the professorship of the law of nations at Lund. In 1672 he published there the work on which his reputation now rests, the treatise *De Jure Naturæ et Gentium* ("On the Law of Nature and Nations"), of which in 1673 he prepared an abridgment with some variations, entitled *De Officio Hominis ac Civis Libri duo* ("On the Duties of a Man and a Citizen"). On the invitation of the king of Sweden he removed to Stockholm, was appointed councillor of state and royal historiographer, and published *Commentarii de Rebus Suecicis ab Expeditione Gustavi Adolphi usque ad Abdicationem Christianæ* (Utrecht, 1676). In 1688 he accepted a similar office, with an annual pension of 2,000 crowns, at the court of Frederick William, elector of Brandenburg, the history of whose reign he published under the title of *Commentarii de Rebus Gestis Frederici Wilhelmi Magni, Electoris Brandenburgici*. In 1694, shortly before his death, and while he was in Berlin, the king of Sweden created him a baron. Of his great treatise, first printed in German at Leyden in 1672, and afterward at Frankfort much augmented (1684), the best edition is that published at Leipsic *cum Notis Variorum* by G. Mascov (2 vols. 4to, 1744). The French translation by J. Barbeyrac (2 vols. 4to, Amsterdam, 1712), with notes, is the version most esteemed. There is an English version by Basil Kennet, with Barbeyrac's preface and notes translated by Carew (London, 1749). Pufendorf wrote several less important works.

PUFF BALL. See LYCOPERDON.

PUFF BIRD, an appropriate name for the *bucconinae*, an American subfamily of diurnal fissirostral birds, placed by Gray in the kingfisher family, but by the older and some modern writers in the scansorial family of barbets or *capitoninae*; the generic name *bucco* is applied by Cuvier to the latter. In the typical genus *bucco* (Linn.), as recognized by Gray, the bill is long, strong, elevated, and very broad at the base, where it is furnished with tufts of strong bristles, and suddenly curved at the tip, which is hooked; the gape very wide; nostrils concealed by the projecting plumes and bristles; wings moderate and rounded, the first quill short and the fourth the longest; tail long, broad, even, rounded on the sides; tarsi shorter than the middle toe, strong, and covered in front with transverse scales; toes two before and two behind, the outer anterior the longest, and the claws long and acute. There are about

Pied Puff Bird (*Bucco macrorhynchus*).

a dozen species described, in tropical South America; the name is derived from their habit of puffing out the plumage of the head, which gives them a heavy and ill balanced appearance. They are solitary, silent, and melancholy-looking, living generally in retired woods, perching on some low and thickly leaved branch, with the large head drawn between the shoulders; thus they remain for hours at a time, occasionally darting after insects, returning to the same perch, which they are said to frequent for months together; they sometimes climb like woodpeckers, supported by the tail, in search of insects in the bark; the nest is made in the hollows of trees; they are not shy, and sometimes select spots near human habitations; their colors are sombre, very different from those of the barbets, with which some authors have classed them. The collared puff bird (*B. collaris*, Lath.) is 7½ in. long; rufous above, striated with black; whitish on the chest, terminated by a broad black band; a similar band across the shoulders; abdomen

rufous white; bill $1\frac{1}{2}$ in. and horn-colored. The pied puff bird (*B. macrorhynchus*, Gmel.) is black, with a black and larger bill; general color black, with forehead, throat, abdomen, and tip of tail white.—Figures of many of these puff birds may be found in Swainson's "Birds of Brazil and Mexico" (London, 1841).

PUFFIN. See **AUK**.

PUGATCHEFF, Yemelyan, a Cossack chieftain and pretender to the throne of Russia, born at Simoveisk on the Don in 1726, executed in Moscow, Jan. 21, 1775. He first appeared as the leader of a band of disciplined robbers. In the seven years' war he served against the Prussians, and subsequently in the Russian campaign of 1769 against Turkey. Returning to his native land, he was imprisoned for seditious conduct; but having recovered his liberty, he went to Yaitzkoi, where a striking resemblance noticed between himself and Peter III. prompted him to pass himself off as the murdered monarch, to forge a tale about his escape from death, and to declare that he was now to set about the task of dethroning Catharine II. and regaining his crown. The insurrection broke out in the middle of 1773, when a manifesto of Pugatcheff in the name of Peter III. was published. After he had got possession of the fortress of Yaitzkoi, and the religious sect of the Raskolniks, of which he had become a member, had embraced his cause, the peasantry went over to his side in large numbers, and many Tartar and Finnish tribes joined him. With these he took numerous fortresses on the Ural, the Volga, and the Don, and marched upon Moscow; but he was betrayed by his comrades for 100,000 rubles to Michelson and Suvaroff. In this insurrection 100,000 lives were lost.

PUGET, Pierre, a French artist, born in Marseilles, Oct. 31, 1622, died there, Dec. 2, 1694. He was apprenticed to a ship builder and wood carver, travelled on foot to Italy, and after suffering great hardships obtained admission to the studio of Pietro da Cortona in Rome. Returning to Marseilles in 1643, he was commissioned by the duke de Brézé to design a magnificent ship, which, in honor of the queen, Anne of Austria, was called *La Reine*, and Puget devoted three years to decorating it with carvings. He next went to Italy again, and spent some years in copying antique monuments and in art and architectural studies. In 1653 he returned to France, and painted many church pictures for Marseilles, Aix, Toulon, Cuers, and La Ciotat. Ill health obliging him to give up painting in 1655, he devoted himself to sculpture and architecture. The gate and the balcony of the city hall at Toulon, which he built and carved, were his first works. He then went to Genoa, where he executed many important works. In 1665 he was recalled to France by Colbert, and appointed director of ship decorations at the dockyard of Toulon, where he also began to build an arsenal; but its progress being hinder-

ed by official intrigues, he retired to his native city. While at Toulon he had partly sculptured in Carrara marble the group upon which his fame mainly rests, his "Milo of Crotona devoured by a Lion." It was finished in 1683, for the gardens at Versailles. His group of Andromeda and Perseus was completed in 1685, and brought to Versailles by his son; three years later he himself went there with his bass relief of Alexander and Diogenes. After his return to Marseilles, he superintended the building of a church, executed his last work in bass relief, "The Plague of Milan," and spent his later years in retirement.

PUGET SOUND, in a general sense, the body of water which extends S. from the E. end of the strait of Fuca, through which it communicates with the Pacific ocean, into the N. W. portion of Washington territory, for a distance in a direct line of about 80 m. Its principal constituents are Admiralty inlet, Puget sound proper, the S. termination of this inlet, and Hood's canal. Admiralty inlet extends from the strait of Fuca a little E. of S., with an average breadth of nearly 6 m., for 70 m., and communicates with the sound proper through the "narrows," 1 m. wide and 4 m. long. The sound extends S. W. from the narrows, ramifying into numerous bays and inlets, and containing many islets. Hood's canal branches off from Admiralty inlet 18 m. S. of the strait of Fuca, and extends S. W., with an average breadth of 2 m., for 50 m., when it bends abruptly and extends N. E. for 15 m., nearly connecting with the waters of the sound. Hood's canal on the one hand and Admiralty inlet and the sound on the other enclose a peninsula, of which Kitsap co. forms the greater part. As determined by the United States coast survey, the coast line of Admiralty inlet measures 334 nautical miles; of Puget sound proper, 280; of Hood's canal, 192; total, 806. These bodies of water are all navigable, and the smaller inlets afford numerous safe, deep, and capacious harbors. The shores are fertile, and are covered with abundant timber. The chief towns are Olympia, the capital of the territory, at the S. extremity; Steilacoom, Tacoma (the N. terminus of the Pacific division of the Northern Pacific railroad), and Seattle, on the E. shore; and Port Townsend, at the N. W. extremity. The sound was named after an officer in Vancouver's expedition.

PUGHE, William Owen, a Welsh author, born at Tyn y Bryn, Merionethshire, Aug. 7, 1759, died June 4, 1835. His original name was William Owen, to which he added that of Pughe late in life, on receiving an inheritance. At the age of 17 he went to London to earn his living, and there made the acquaintance of Owen Jones, a tradesman, with whose support and encouragement he entered upon the study of ancient Welsh literature. The two published in conjunction in 1789 the poems of Dafydd ap Gwilym, a bard of the 14th century. This was followed by the works of

other poets and by translations; and in 1801, a third Welshman, Edward Williams, being associated with them, they published the first two volumes of the "Myvyrian Archaeology;" a third volume appeared in 1807. Pughe also prepared a Welsh and English dictionary (1793-1803), and the "Cambrian Biography" (1803); published a Welsh magazine entitled *Y Greil*; and translated into Welsh the "Paradise Lost," Heber's "Palestine," and other poems.—His son, ANEURIN OWEN (1790-1851), who dropped the name of Pughe, edited "Ancient Laws and Institutes of Wales," printed by the record commission in 1841.

PUGILISM (Lat. *pugil*, a boxer), the art of fighting with the fists, practised in modern times according to certain rules, known as the rules of the English prize ring. It is said that Theseus was the inventor of the art of boxing, or the skilled use of the fists and arms in assault and defence. Homer describes pugilistic encounters, and Pollux, Hercules, and others are mentioned as excelling in pugilism. Boxing was one of the most important exercises in the Olympic games. The ancient pugilists fought with the *cestus*, formed of strips of leather wound around the fist and arm, frequently as far up as the elbow. This was sometimes studded over the fist with knobs loaded with lead or iron, and was practically the same as the brass knuckles of the present day. The *cestus* used by the Greeks was of various kinds, called *μελίχαι*, *σπίραι*, *βοείαι*, *σφαίραι*, and *μύρικες*. The *μελίχαι* were the softest, and the *μύρικες* the hardest. The rules of boxing in ancient times resembled those of the modern prize ring, except that wrestling was not permitted. The right arm was used chiefly in offence, the left arm serving to protect the person. The ears were much exposed to injury in the old games, and they were sometimes protected by covers. With the *cestus*, especially when loaded with knobs of metal, the ancient pugilistic encounters must have been terribly severe, resulting often in mutilation, and sometimes in death. At the Olympic games the boxers were usually naked, or wore simply a girdle around the loins. In the earliest times boxing at the games was permitted only between freemen and those who had not committed crime. Contests between boys were early introduced at Olympia.—The art of boxing, as now practised, may be said to date from the building in London of a theatre for exhibitions of the "manly art of self-defence" by one Broughton, about 1740. Broughton, who for 18 years was champion of England, is said to have invented boxing gloves. He held exhibitions in his theatre, and laid down certain rules for fighting, quite similar to those of the present day. But for many years before the time of Broughton pugilistic encounters had been common at fairs and festivals in England. The funds for the erection of Broughton's theatre were provided by about 80 of the noblemen and gentry of England, and the en-

counters were witnessed by the best blood in the land, including the prince of Wales. Jackson, who was champion in 1795, is now regarded as having been one of the most skillful professors of the art. He gave instruction to many of the aristocracy, among whom were Lord Byron and Shaw, the life-guardsmen. The prominent points in Jackson's system were the use of the legs in avoiding blows and the correct estimate of distance, striking no blows out of range. In 1817 the future emperor Nicholas of Russia witnessed a prize fight in England, and shook hands with the victor. Since that time the prize ring has gradually fallen into disrepute; but for a long time the principle of "fair play" was strictly adhered to in England. At the present day prize fighting is practised only in Great Britain and America. The brutality of such exhibitions has at last excited the general condemnation of society, and for more than half a century the practice has been under the ban of the law. The rough character of the assemblages on such occasions, and the frequent "selling out" and fraud in the encounters, have disgusted those of the patrons and professors of the "manly art" who believed in fair play. It is thought that very few of the fights which have occurred within the past few years have been honestly conducted.—Although prize fighting has deservedly fallen into disrepute, many persons practise boxing for exercise and amusement, the rules being essentially those of the prize ring (commonly abbreviated to P. R.). The present rules are briefly as follows. The ring shall be on turf, formed of a square of 24 ft., bounded by a double line of ropes attached to eight stakes. The lower rope is 2 ft. and the upper 4 ft. from the ground. The choice of "corners" is determined by the toss of a coin. The winner of the choice selects his corner according to the state of the wind and the position of the sun, it being an advantage to have the sun in his opponent's face. The loser takes the opposite corner. A space is marked off in each corner large enough to accommodate the man, his second, and his "bottle-holder," who are allowed to attend their man in the ring. The colors of the men are tied around the stakes at their respective corners. Each man names his second and bottle-holder. The seconds agree upon two umpires, one for each man. The umpires usually select a referee, unless one be agreed upon in some other way. The referee directs the contest, and decides the fight and all questions of fairness, and his decision is binding and final. The umpires watch the fight in the interests of their respective men, and call upon the referee for a decision regarding all questions of fairness. The referee withholds all expressions of opinion until he is appealed to by the umpires, or until the close of the fight. The referee and umpires are so placed as to be able to watch the fight, but no one is allowed within the ring except the men with their seconds

and bottle-holders. The men are stripped before the fight by their seconds and dressed for the contest. The dress is usually knee breeches or drawers, stockings, and shoes, the soles of the shoes being provided with spikes three eighths of an inch long and one eighth of an inch broad at the points. The men are naked above the belt. The seconds and umpires see to it that no improper articles are used in the dress. The men are allowed nothing in their hands, and no resin or other sticky substance is allowed upon the fists. One of the umpires is selected to act as time-keeper. It is his duty to call "time" at the expiration of 30 seconds after each round. If one of the contestants fails to come to "the scratch" within eight seconds after time has been called, he is considered to have lost the fight. The scratch is a straight line drawn through the centre of the ring between the two corners. The bottle-holder is provided with a bottle of water and a sponge, and it is the duty of the second and bottle-holder to take their man to his corner at the close of each round, render him all needed assistance there, and bring him to the scratch when time is called. The second and the bottle-holder are not permitted to approach their man during a round, or to give him advice at that time, and are cautioned not to injure the antagonist when they pick up their man at the close of a round. When the man cannot come to the scratch at the call of time, the second usually throws up the sponge as a token of defeat, and the victor takes his antagonist's colors as a trophy. The men being ready, time is called, and each man is conducted to his side of the scratch by his second. The men shake hands with each other, the seconds do the same, the latter retire to their corners, and the fight begins. When time is called after a round, the principal rises from his second's knee, and walks unaided to the scratch. A round is considered closed when one or both men are down, either from a knock-down blow or from being thrown after they have closed. Unless there is a knock-down, the rounds usually terminate in a clinch. The following acts are considered foul: wilfully falling without receiving a blow at the time of falling, except that one may slip from the grasp of his antagonist after the men have closed; butting with the head, gouging, scratching, biting, kicking, or falling upon the antagonist when he is down; striking the antagonist below the belt, or grasping him by the legs, and striking the antagonist when he is down (a man with both knees or with one hand and one knee upon the ground is considered down). If one of the umpires claim a foul, the referee may caution the man and his second, or may declare that the man against whom the foul is claimed has lost the fight. The referee's judgment is usually based upon his opinion as to whether the foul was intentional. In case of disputes, the men retire to their respective corners pending the decision of the

referee. In case any circumstance interfere with the progress of the fight, the referee may appoint another time or place of meeting, at which the fight is to be continued; but unless it is concluded within a week, the battle is considered drawn. The referee has power to cause the men to be separated when one is in such a position across the ropes as to be helpless or in danger of his life.—The first prize fight in the United States took place in 1816, between Jacob Hyer (father of the celebrated Tom Hyer) and Tom Beasley, the result of which was a draw. The rules of the ring were observed during the first part of this fight, but it soon degenerated into rough-and-tumble, and friends of the men interfered after one of Hyer's arms had been broken. This was followed by numerous fights of a more scientific character. Among the most celebrated was the fight between Tom Hyer and "Yankee" Sullivan, in 1849. Numerous other fights occurred between 1849 and 1860, when the so-called great international fight took place in England between John O. Heenan of New York and Tom Sayers, champion of England. This was very severe, and the general opinion has been that Heenan was the winner, although no decision was given by the referee, the fight being interrupted by breaking in the ring.—In the accounts of fights, particularly those published in the earlier history of the English ring, the slang words and expressions used are peculiar, and some of them are quite descriptive and suggestive. The following are some of those commonly met with in pugilistic writings: "Bellows," lungs; "bellowser," a blow in the pit of the stomach, taking one's breath away; "blinker," a blackened eye; "bore," to press a man down by force of weight and blows; "brain canister," "knowledge box," "lob," "lolly," "nob," the head; "buff," the bare skin, as "stripped to the buff"; "cant," a blow; a "cant over the kisser," a blow on the mouth; "castor," a hat (before entering the ring, the pugilist generally tosses in his "castor"); "chancery," a position in which a pugilist gets his opponent's head under his arm; "claret," blood; "claret jug," "conk," "nozzle," "proboscis," "snuff box," "snorer," "snout," the nose; "cork," to give a bloody nose; "daylights," "goggles," "peepers," "squinters," the eyes; "fancy," a general name for pugilists; "fibbing," striking blows in quick succession at close quarters; "fives," "a bunch of fives," the fist; "fives court," a boxing hall; "send to grass," to knock down; "groggy," used to describe the condition of a pugilist when he comes to the "scratch" weak on his "pins," "grubber," "kisser," "oration trap," "potato trap," "whistler," "ivory box," the mouth; "mauley," the fist; "mill," a fight; "mourning,"—"to put the eyes in mourning," to blacken the eyes; "painted peepers," blackened eyes; "pins," the legs; "portmanteau," the chest; "rib roaster," a blow on the ribs;

"smeller," a blow on the nose.—A closely contested prize fight taxes a man's strength, endurance, and "pluck" to the utmost; and, however courageous he may be, poor physical condition is so great a disadvantage that it can hardly be overcome in the face of good condition of an antagonist, the skill, courage, and strength of the men being equal. It has therefore been considered of the last importance to bring a man into the ring perfectly trained. The duration of rigid training depends largely upon the previous muscular condition; but two or three months are usually sufficient. Without going into the minutiae of the different training systems, it will be sufficient to indicate the general method and the main objects to be attained. Fat is inert, useless matter during a fight, and is to be eliminated from the body as far as is possible without depressing the nervous energy. The muscular system should be developed to the highest degree. The nervous system should act promptly and perfectly, a condition essential to endurance, which is probably the most important quality in a pugilist. The respiration should be free and performed with the smallest expenditure of nervous and muscular force. Finally, the temper and judgment should be clear, the skill as great as possible, and the man should have the moral and physical force to fight to the last extremity of endurance. To secure these ends, the diet is restricted to lean and easily digestible meats, stale bread or toast, a small quantity of vegetables, and a very moderate quantity of liquids; but the amount of food should be sufficient to satisfy the appetite, never allowing the nervous system to become depressed. The exercise is such as to develop the general muscular system, particularly the muscles employed in hitting, and the legs. To secure perfect condition of the nervous power, all sources of mental irritation are avoided, sexual intercourse is interdicted, and stimulants, if taken at all, are used with care and in very small quantity. Tea may be used moderately once a day, without sugar or milk; a glass of sherry with a raw egg or a glass of old ale may be taken once a day, though it is generally best to avoid alcohol. It is of the greatest importance to secure perfect and tranquil sleep, which is a good indication of the condition of the nervous system. If a man is in good health, purgatives, with which the training sometimes begins, are unnecessary. The bowels may be kept regular by varying the diet, and oat-meal gruel is frequently used with this end in view. Perfect action of the skin should be secured by proper ablutions after exercise. Fat may sometimes be removed from particular parts by local sweating with bandages. It is especially important to remove fat from the face and to harden the skin and subcutaneous cellular tissue, so that the "punishment" will not puff up the face, particularly about the eyes, which sometimes become closed by swelling under the blows of the

antagonist. A man is not in good condition unless the skin be bright, clear, and free from blotches or pimples. A constitutional taint, such as syphilis, usually shows itself during a course of severe training, and the man breaks down or "goes stale." The wind and endurance are developed by boxing and running. The man boxes with his trainer or strikes at the bag for several hours each day, and runs at a moderate pace from six to ten miles, doing a quarter or half of a mile at the top of his speed. This shakes the abdominal organs, promotes the removal of fat from the omentum, and gives play to the diaphragm, while at the same time it gives agility and power to the legs. The trainer should have his man under complete subjection, and never leave him, night or day, during the whole course of training. He learns, if possible, the points and style of fighting of his adversary, and generally fixes upon a plan of battle. He boxes with his man constantly, hits him hard, and accustoms him to bear punishment without loss of temper or judgment. His man should go into the ring confident that he will win the battle. For at least 24 hours immediately preceding the fight the man should rest. Many trainers bring down the weight of their men by diet and sweating below the point at which they are to fight, depressing the system somewhat at first, and then allow the weight to come up to the proper point, so that they fight when the system is at its maximum of reaction and in perfect condition. In the articles of agreement of a prize fight, the weight at which the men are to fight is usually stipulated. When no such stipulation is made, the men are said to fight at "catch weight," or at such weight as they may think proper. A man may fight at less than the stipulated weight, but he is ruled out if he is over weight. Pugilists are usually classed with regard to weight as follows: a man of 115 lbs. or under is called a feather weight; between 115 and 130 lbs., a light weight; between 130 and 150 lbs., a middle weight; at 150 lbs. or over, a heavy weight.—Boxing, which is practised for exercise and amusement and in training for a prize fight, is conducted according to the rules of the ring, and the hands are provided with gloves padded with hair on the back to the thickness of two or three inches, so that the blows are much less severe than with the naked fist. Glove fights are sometimes practised at public exhibitions in exact accordance with pugilistic rules, and these are frequently quite severe. Occasionally the gloves are blackened so as to leave a mark when a man is hit, each blow being counted by the judges. Boxing constitutes the greatest part of so-called pugilistic science, and different professors of the "manly art" usually have different methods or styles. The most important principles of boxing are as follows. The position is with the left foot forward, the feet separated 16 or 18 in. according to the size of the man. The

weight rests mainly upon the right leg, the left leg being free to advance. The body is erect, the head easily poised and erect, so that the movements are free, and the hands are placed at about the level of the upper part of the chest, with the fists closed and the arms slightly bent. The left hand is somewhat in advance of and lower than the right, and is used mainly for striking when the antagonist is just within distance. The right hand is used in guarding blows of the left and in close work. A boxer keeps his eyes constantly fixed upon the eyes of his opponent, ready to hit or guard when occasion offers. Sparring technically means the movements of the hands to and fro, which are constantly made when boxers are in position. The main point in striking a first blow, or "lead-off," is to deliver the blow without any "show" or warning, and so quickly that the opponent cannot defend himself. In boxing, feints are frequently made to direct the attention of the adversary from the place where the real blow is to be delivered. The blows of all good boxers are struck straight from the shoulder, and the most effective blows are those into which the whole weight of the body is thrown. It is not correct judgment to strike a blow unless the distance and position of the opponent be such that the blow will probably "get in." A "chopping" blow is one in which the fist is brought from above downward. This blow is frequently used by good boxers in returns, but is not a good blow as a lead-off. The great point in striking is to hit quickly, straight, and as hard as possible. One solid blow is worth a hundred light taps. Rounding blows are seldom if ever used by good boxers, as these are not efficient and they expose the person. The most efficient blows are about the face and neck, on the pit of the stomach, and over the lower ribs. All blows below the waist are foul. Blows are avoided by guarding, jumping back, dodging with the head, &c. Dodging the head is very useful, and is practised in making many of the so-called "points." A very slight movement of the arm upward in front of the face is sufficient to cause a powerful blow to glance off. A movement of the arm downward across the body wards off a body blow. In hitting, the large knuckles should strike, and the back of the hand should be turned downward. In real fights points are seldom used, and the practical work is done by plain hitting and guarding of the head and body. The "counter" is a very effective blow, as it meets the man while he is advancing. This is a great practical point with good boxers. The man watches his opponent closely, and when he thinks he is about to lead off he strikes, hoping that his blow will get in before that of his adversary. At the same time he endeavors to guard his adversary's blow. A plain counter is when both men strike at nearly the same instant, with corresponding hands. If a man be remarkably quick in countering, he often

demoralizes his adversary, who becomes afraid to make a full lead-off, under the apprehension of the counter blow. A man may counter either upon his opponent's head or body. In countering, the opponent's blow is sometimes avoided by dodging the head to one side. If the head be dodged backward, the force of the counter is lost, and the opponent may get in a severe blow in following up. When the opponent has received a heavy blow, it is well to follow up the advantage with close work and to keep the man moving, so that he has no time to recover himself. Close work, rapid blows at close quarters, or "fibbing," requires great skill and judgment. The blows in close work should always be straight, as they protect from the blows of the adversary. Such quick work, however, is a great strain on the wind and endurance. Right-hand work is very effective in close quarters. In making points the right hand is very useful. A man dodges his head to one side to avoid his opponent's lead-off with the left, and strikes his opponent with the right in the face (called a cross counter, because the right arm crosses the adversary's left), or he strikes his opponent in the body. Another point is to drop the head quickly under the arm of the opponent when he strikes, and to deliver blows right and left when the head is raised. Another point is to strike the opponent's left-hand blow aside with the palm of the left, and immediately strike with the right. Another is to strike the left-hand lead-off up with the left elbow, and strike immediately a chopping blow with the same hand ("peak and chop"). Numerous points such as those just mentioned are used, particularly in "fancy" boxing; but they can hardly be described clearly, even with the aid of illustration by drawings. Most of these "points" require great confidence, as the man advances to meet his opponent as he strikes, avoiding the blows mainly by dodging, or "head work." There is no such thing as boxing without a master. A good boxer must have great practice and must box with many different persons. Clinching, chancery, and throwing are fair, so long as a man does not grasp his opponent's legs; but these manœuvres are not often practised in friendly boxing with gloves. A man steps in with his left foot, throws his left arm around the neck or chest of his opponent, and tosses him backward, the buttocks being crossed. This is called the "cross-buttock throw." Another throw is to step in with the right foot, throw the right arm around the opponent's waist, and throw him over the hips (the "hip throw"). Many throws and trips are used in fighting, and each has its counter movement. Throwing in the ring differs from ordinary wrestling, as a man grasps his opponent wherever he can above the belt. The different kinds of chancery consist in rushing in when the opponent strikes, or in close quarters, and throwing either arm around his neck, striking him as hard and as

often as possible in this position. Each chan-
cery has its counter movement, by which a
man may sometimes extricate himself. The
"upper cut" is generally used in close quar-
ters. It consists in striking from below up-
ward with the back of either hand, hitting
the man under the chin or in the face, accord-
ing to his position. Some boxers take a posi-
tion occasionally with the right foot advanced,
instead of the left; but this position is not
considered good, and it is much more difficult,
with the right foot advanced, to protect the
body.—See Egan, "Boxiana, a Sketch of An-
cient and Modern Pugilism" (5 vols., London,
1818); Brandt, "Habet! A Short Treatise on
the Law of the Land as it affects Pugilism"
(London, 1857); "Fistiana" (24th ed., London,
1863); Maclaren, "Training, in Theory and
Practice" (London, 1866); Harrison, "Ath-
letic Training and Health" (London, 1869);

et seq. (New York, 1870); "The Slang Dic-
tionary" (London, 1870); and "American
Fistiana, from 1816 to 1873" (New York,
1874). "Bell's Life in London" contains ac-
counts of the most important English prize
fights, and Wilkes's "Spirit of the Times"
(New York) of English and American fights.
The "Spirit of the Times" for May 5, 1860,
contains a full account of the fight between
Heenan and Sayers.

PUGIN. **I.** Augustus, an English architectural
draughtsman of French extraction, born in
Normandy in 1769, died in London, Dec. 19,
1832. He made many architectural drawings
for engraving, but is best known by a series of
elaborate works on the Gothic architecture of
the middle ages. These comprise "Specimens
of Gothic Architecture selected from various
ancient Edifices in England," &c. (2 vols. fol.
and 4to, with 114 plates, 1821-'3), the descrip-
tions of which were written chiefly by E. J.
Wilson; "Architectural Illustrations of the
Buildings of London" (2 vols. 4to, 1824), and
"Specimens of the Architectural Antiquities
of Normandy," &c. (1825-'8), both published
in conjunction with John Britton the anti-
quary. He also prepared, with the assistance
of his son, "Gothic Ornaments selected from
various Buildings in England and France."

II. Augustin Welby Northmore, son of the pre-
ceding, born in London, March 1, 1812, died
at Ramsgate, Sept. 14, 1852. He designed or-
namental Gothic furniture and metal work,
and published "Designs for Gothic Furniture
in the Style of the 15th Century" (1835), "De-
signs for Iron and Brass Work in the Style of
the 15th and 16th Centuries" (1835), "De-
signs for Gold and Silversmiths' Work" (1836),
and "Ancient Timber Houses" (1836), all of
which had a material influence in promoting a
revival of the taste for Gothic forms. He also
published "Contrasts, or a Parallel between the
Noble Edifices of the 14th and 15th Centuries
and similar Buildings of the present Decay of
Taste" (2d ed., 1841). Becoming a convert to

the Roman Catholic faith, he devoted himself
to the study of ecclesiastical Gothic architec-
ture, and thereafter invariably declined to de-
sign for Protestant places of worship, and sel-
dom accepted commissions from Protestants.
The chief exceptions to this rule were the gate-
way to Magdalen college, Oxford, and the elab-
orate mediæval ornamentation of the new par-
liament houses. He purchased an estate at
Ramsgate, and erected a house, church, schools,
&c., all of which were dedicated to St. Augus-
tine. His chief publications besides those men-
tioned are: "Examples of Gothic Architecture"
(3 vols. 4to, 225 plates, 1838); "True Prin-
ciples of Pointed or Christian Architecture"
(1841); "An Apology for the Revival of
Christian Architecture" (1843); and "Glos-
sary of Ecclesiastical Ornament" (1844).—See
"Recollections of A. W. N. Pugin, and his
Father, Augustus Pugin, with Notices of their
Works," by Benjamin Ferrey, with an appen-
dix by E. Sheridan Purcell (1861), and "Pho-
tographs from 500 sketches by the younger
Pugin" (2 vols., 1865). **III.** Edwin Welby, an
English architect, son of the preceding, born
March 11, 1834, died in London, June 7, 1875.
He completed his father's unfinished works,
and designed hundreds of churches and other
public buildings in England and Ireland.
Among his works are the orphanages of Hel-
lingly and Bletchingly, the Carmelite church
at Kensington, and the cathedral at Queens-
town, near Cork, in conjunction with Mr.
Ashlin. In 1873 he was involved in a suit for
libel with the painter Millais.

PUJOL, Abel de. See ABEL DE PUJOL.

PULASKI, the name of counties in seven of
the United States. **I.** A S. W. county of Vir-
ginia, bordered E. partly by New river, which,
turning W., intersects it toward the south,
Little river, a branch of New, completing the
E. boundary; area, about 300 sq. m.; pop. in
1870, 6,538, of whom 1,809 were colored. It
lies between two mountain ranges, Walker
mountain on the northwest and the Blue Ridge
on the southeast. The surface is broken and
the soil generally fertile. The Atlantic, Mis-
sissippi, and Ohio railroad passes through it.
The chief productions in 1870 were 38,411
bushels of wheat, 96,690 of Indian corn, 27,-
301 of oats, 2,817 tons of hay, 18,580 lbs. of
tobacco, 9,605 of wool, and 53,100 of butter.
There were 1,104 horses, 1,147 milch cows,
4,169 other cattle, 2,018 sheep, and 4,347
swine. Capital, Newbern. **II.** A central
county of Georgia, intersected by the Ocmul-
gee and Little Ocmulgee rivers, and drained
by their branches; area, about 650 sq. m.;
pop. in 1870, 11,940, of whom 5,948 were
colored. It has a level surface toward the
south and rolling toward the north. The Ma-
con and Brunswick railroad and the Hawkins-
ville branch intersect it. The chief produc-
tions in 1870 were 215,375 bushels of Indian
corn, 13,646 of oats, 20,432 of sweet potatoes,
17,320 lbs. of butter, 15,444 of wool, and 6,617

bales of cotton. There were 855 horses, 940 mules and asses, 2,868 milch cows, 6,230 other cattle, 6,767 sheep, and 12,728 swine. Capital, Hawkinsville. **III.** A central county of Arkansas, intersected by the Arkansas river and drained by its branches; area, 1,200 sq. m.; pop. in 1870, 32,066, of whom 5,948 were colored. In the south the surface is level, and in the north and west hilly, and the soil is moderately fertile. Lead, slate, and excellent granite are found. It is intersected by the Memphis and Little Rock, the Little Rock and Fort Smith, and the Cairo and Fulton railroads. The chief productions in 1870 were 9,673 bushels of wheat, 516,519 of Indian corn, 16,442 of oats, 26,252 of Irish and 41,743 of sweet potatoes, 161,310 lbs. of butter, and 14,891 bales of cotton. There were 2,388 horses, 1,913 mules and asses, 4,341 milch cows, 5,514 other cattle, 2,288 sheep, and 24,977 swine; 2 manufactories of boots and shoes, 1 of carriages and wagons, 4 of clothing, 3 of furniture, 2 of iron castings, 2 of machinery, 2 of sash, doors, and blinds, 3 of tin, copper, and sheet-iron ware, 2 of cigars, 1 planing mill, and 10 saw mills. Capital, Little Rock, which is also the capital of the state. **IV.** A S. E. county of Kentucky, bordered S. by the Cumberland river, and E. by the Rock Castle; area, about 550 sq. m.; pop. in 1870, 17,670, of whom 1,075 were colored. It has a diversified surface, with several elevated ranges, and contains iron, lead, and coal. The chief productions in 1870 were 43,918 bushels of wheat, 466,379 of Indian corn, 176,016 of oats, 34,790 of Irish and 21,709 of sweet potatoes, 279,716 lbs. of butter, 37,341 of wool, 47,749 of tobacco, and 2,252 tons of hay. There were 4,354 horses, 1,187 mules and asses, 4,631 milch cows, 1,655 working oxen, 4,747 other cattle, 21,579 sheep, and 22,570 swine. Capital, Somerset. **V.** A N. W. county of Indiana, intersected by Tippecanoe river; area, 435 sq. m.; pop. in 1870, 7,801. It has a nearly level surface, about equally divided between prairie and oak openings, and a generally fertile soil. It is intersected by the Pittsburgh, Cincinnati, and St. Louis, and the Louisville, New Albany, and Chicago railroads. The chief productions in 1870 were 87,640 bushels of wheat, 12,035 of rye, 60,512 of Indian corn, 25,186 of oats, 50,102 of potatoes, 147,015 lbs. of butter, 22,266 of wool, and 14,442 tons of hay. There were 2,576 horses, 3,341 milch cows, 5,427 other cattle, 7,823 sheep, and 5,008 swine. Capital, Winamac. **VI.** A S. county of Illinois, separated from Kentucky by the Ohio river and bordered N. W. by Cache river; area, about 175 sq. m.; pop. in 1870, 8,752. It has a level and well wooded surface and a fertile soil. It is intersected by the Illinois Central and the Cairo and Vincennes railroads. The chief productions in 1870 were 44,922 bushels of wheat, 195,735 of Indian corn, 16,511 of oats, 24,652 of potatoes, and 157,000 lbs. of tobacco. There were 871 horses, 842 milch

cows, 1,736 other cattle, 1,380 sheep, and 5,715 swine. Capital, Mound City. **VII.** A S. county of Missouri, intersected by the Gasconade river and drained by several of its branches; area, 1,332 sq. m.; pop. in 1870, 4,714, of whom 25 were colored. The surface is hilly and the soil generally fertile. It is intersected by the Atlantic and Pacific railroad. The chief productions in 1870 were 28,037 bushels of wheat, 201,019 of Indian corn, 20,873 of oats, 9,020 lbs. of tobacco, 7,150 of wool, 75,580 of butter, and 6,052 gallons of sorghum molasses. There were 1,481 horses, 1,271 milch cows, 2,949 other cattle, 3,886 sheep, and 10,154 swine. Capital, Waynesville.

PULASKI, Casimir (Pol. KAZIMIERZ PULAWSKI), count, a Polish soldier, born in Lithuania, March 4, 1747, died from a wound received in the attack on Savannah, Oct. 11, 1779. He was the son of a Polish nobleman, the starosta of Wareck, who was the chief organizer of the confederation of Bar, which was signed by his three sons (1768). Casimir, who had acquired military experience in the service of Duke Charles of Courland, entered heartily into the war for the liberation of his country. Forced to cross the Dniester, he took refuge after the storming of Bar in the monastery of Berditchev with 300 men, and after sustaining a siege of several weeks capitulated on the condition that the garrison should be set at liberty. He himself was not freed until he had pledged himself to bear proposals for a reconciliation to the chiefs of the confederates; but as soon as he was set at liberty he refused to keep a promise extorted by force. Joining his father in Moldavia, he made incursions across the Dniester, and attacked the Russians and fortified posts within the Polish borders. He carried on a desultory warfare in various parts of the country, until an unsuccessful attempt to gain possession of the person of King Stanislas Augustus, in 1771, caused a sentence of outlawry and death to be passed against him, on the ground that it was his intention to assassinate the monarch. The coalition of Austria, Russia, and Prussia for the conquest and division of Poland was soon after completed, and resistance became hopeless. Pulaski, who had lost his father and brothers in the war, made his way to Turkey, and afterward went to France, where he offered his services in the American cause to Franklin. With high recommendations to Washington he arrived at Philadelphia in the summer of 1777. He at first served in the army as a volunteer; but four days after the battle of Brandywine, in which he distinguished himself, he was appointed by congress commander of the cavalry with the rank of brigadier general. After five months he resigned his command, and entered the main army at Valley Forge in March, 1778, where he proposed to organize an independent corps of cavalry and light infantry, to which congress assented. By October 330 men were in this corps, which was called Pu-

laski's legion. With this he marched, in February, 1779, to South Carolina, reached Charleston May 8, and vigorously opposed the project of surrendering the place to the British army then before the city. On May 11 he attacked with his legion the British advance guard, and was repulsed with considerable loss in killed, wounded, and prisoners, he himself escaping with difficulty to the American lines. In September the French under Count d'Estaing and the Americans prepared to besiege Savannah. On Oct. 9 it was determined to carry the town by assault. Pulaski was placed at the head of the French and American cavalry, and during the engagement received a mortal wound. He was taken on board the brig *Wasp*, which lay in the Savannah river, died after lingering two days, and was buried in the river. A monument to his memory voted by congress has never been erected, but one was raised by the citizens of Georgia in Savannah.

PULCI, Luigi, an Italian poet, born in Florence in 1431, died there in 1487. He held an inferior office under the republic, and was one of those for whom Lorenzo de' Medici kept a place at his table. His *Morgante Maggiore*, treating the legend of Charlemagne and his paladins, was first published in Florence in 1481. One canto of it was translated into English by Lord Byron. Pulci also wrote sonnets and other short pieces.

PULLEY. See MECHANICS, vol. xi., p. 327.

PULMONARIA. See LUNGWORT.

PULQUE, an aboriginal Mexican name for the fermented juice of *agave Americana*, the American aloe, maguey, or century plant (see AGAVE), which is cultivated in southern Mexico, as well as in Central and South America, for this and other products. The plant cannot be utilized for pulque until it has completed its growth and is about to flower, a time which varies with the soil and location from 5 to 15 years. The sap stored up in the long and very fleshy leaves for the rapid development of the flower stalk abounds in sugar and mucilage. As soon as there are indications of the shooting up of a flower stalk from the centre of the plant, the central leaves and forming bud are cut out, a cavity being formed in their place, into which the sap will flow; the cavity is shaded by drawing over some of the outer leaves and tying their points. A vigorous plant will yield about two gallons a day for four or five months; as it quickly ferments, the juice is gathered from the plant three times a day in earthen jars, which are emptied into reservoirs made of raw hide tacked to a wooden frame. A portion of the juice is disposed of as pulque, *i. e.*, simply fermented, while the greater part is distilled to form a strong alcoholic liquor, called pulque brandy, aguardiente, mezcal, and by other names. Pulque is a favorite drink with the Mexicans, and in the towns is sold in the market places and at shops called *pulquerias*,

where the strong liquor is also kept. Taken in an early stage of fermentation, when the liquid is brisk with the bubbles of carbonic acid that are given off, pulque is a pleasant drink, not unlike spruce beer; but if allowed to complete its fermentation, which it does in three or four days, and reach the condition in which Mexicans like it best, no uneducated stomach can tolerate it; it contracts the odor of putrid animal matter from the skin in which it is fermented, and is exceedingly repulsive. Among the Mexicans the pulque from certain localities or plantations is especially esteemed, as among Europeans preference is given to the wine of certain vineyards. When the flow of sap ceases, the plant dies, but not without having formed innumerable offsets by means of which the plantation may be renewed.

PULSATILLA. See ANEMONE.

PULSE (Lat. *pulsare*, to beat), the throbbing of the arteries caused by the intermitting impulses communicated to the blood by the heart's contractions, propagated as a wave by the elasticity of the arteries, perceptible to the touch in all but the smallest vessels, and visible when they are superficial or exposed; the pulsation being nearly synchronous with the contraction of the left ventricle. At each pulsation the capacity of the artery is augmented by an increase of diameter and by a partial elongation, the vessel being thereby lifted from its bed; this increase has been estimated for the carotid artery as $\frac{1}{3}$ part, but this can be only an approximation. The pulsation of the larger arteries in the immediate neighborhood of the chest, as for example the carotids, is perceptibly synchronous with that of the heart; but for those at a distance, a slight interval of time is required for its propagation. Thus the pulse of the radial artery at the wrist is sensibly later than that of the heart, and that of the posterior tibial artery, at the ankle joint, later still. But this interval in each instance is very short, and requires careful attention to be distinguished. The pulse is liable to vary, within the limits of health, from the diversities of age, sex, stature, muscular exertion, condition of the mind, state of the digestive process, and period of the day. The following table is given by Carpenter as an approximation to the average frequency of the pulse per minute at different ages:

In the fetus.....	140 to 150
Newly born infant.....	130 to 140
During the 1st year.....	115 to 130
" " 2d ".....	100 to 115
" " 3d ".....	95 to 105
" " 7th to 14th year.....	80 to 90
" " 14th to 21st ".....	75 to 85
" " 21st to 60th ".....	70 to 75
In old age.....	75 to 80

According to Dr. Guy, the pulse of the adult female usually exceeds that of the adult male of the same age by 10 to 14 beats a minute; according to Volkmann, the pulse is less frequent as the stature is greater, about four beats for half a foot in height. It is well known

that muscular exertion increases the frequency of the pulse. The effect of posture has thus been expressed by Dr. Guy:

Average beats per minute in	Standing.	Sitting.	Lying.
Healthy males.....	81	71	66
Healthy females.....	91	84	79

According to this, the difference between standing and lying in the former is one fifth of the whole, in the latter one eighth; when this change is effected by muscular effort the variation is greater, accounting for many cases of sudden death in persons with disease of the heart or in very weak conditions on quickly assuming an erect position. Mental excitement, the digestive process, alcoholic drinks, and elevation above the sea level, accelerate the pulse; as a general rule, though with numerous exceptions, it is more frequent in the morning than in the evening, and in sanguine than in lymphatic temperaments. The pulse is slower during sleep, and from the effect of rest, diet, cold, venesection, and the action of many drugs, especially digitalis, aconite, and hellebore. The pulse may be counted in any artery, and in a manner familiar to all, but most conveniently in the radial at the wrist, in the carotids, temporals, brachial, or femoral. The average numerical proportion of the arterial pulsations to the respiratory movements is 4 or 5 to 1; when this proportion is widely departed from, there is either some general diseased condition of the system accompanied with fever, some obstruction to the proper aëration of the blood, or some disorder in the nervous system; in inflammatory or acute diseases, the pulse may rise to 120 and 160 in the adult, and so that it cannot be counted in the child; in pneumonia, with the quickened pulse the number of respirations increases more rapidly, the above proportion becoming as 3 or even 2 to 1; in hysteria a similar increase may occur in both without any serious cause.—The exact form of the arterial pulse has been determined by means of a contrivance termed the "sphygmograph," which consists of a small metallic or ivory plate, held in contact with the integument immediately over the vessel by means of a delicate spring, and lifted from its bed by each pulsation of the artery. The plate carries an upright rod, which in its turn moves a long but light index, the end of which traces an alternately ascending and descending line upon the surface of a strip of paper moving with uniform velocity. Thus the extent of the vertical motion measures the width of the arterial expansion; and its greater or less obliquity, as traced upon the paper, indicates its rapidity or slowness, as compared with the horizontal movement of the paper itself. Such a trace is very useful, first by showing minute peculiarities of the arterial pulsation, too small to be distinctly perceptible by the touch; and sec-

ondly, by leaving them in the form of a permanent record, suitable for subsequent study and comparison. The ordinary trace of the radial pulse, taken in this way, consists of a nearly vertical ascending line, which indicates the sudden and rapid expansion of the artery, followed by an oblique and somewhat undulating descent, showing the comparatively slower and more irregular collapse of the vessel. These two ascending and descending lines are repeated for every pulsation of the artery.

FIG. 1.—Trace of the Radial Pulse, taken by the Sphygmograph.

Sometimes the undulations of the descending line become more perceptible, owing to an increase of temperature or some other cause which diminishes the resistance of the arterial walls to the heart's impulse; and under these circumstances the expansion of the vessel is more sudden and vertical, while its collapse is indicated by one or two well marked oscillations, in the trace of the descending line. In

FIG. 2.—Trace of the Radial Pulse under the influence of Increased Temperature.

certain cases of disease this oscillation of the artery at the period of collapse becomes so marked that a sort of secondary beat, or reduplication of the pulse, is perceptible even to the touch; and this constitutes what is known as the double or dicrotic pulse, in which there are two perceptible pulsations of the artery for every contraction of the heart. Of these two

FIG. 3.—Trace of a Dicrotic Pulse, in Typhoid Fever.

pulsations, only the first is directly caused by the impulse of the heart; the second is due to the oscillation of the blood in the relaxed arterial tube. Dr. E. R. Hun, who at that time was special pathologist to the New York state lunatic asylum at Utica, published in the "American Journal of Insanity" for January, 1870, the results of a series of investigations, in which he found that the pulse of the insane "always tends toward the dicrotic or mono-

FIG. 4.—Trace of Pulse in Dementia.

crotic type, being never tri-crotic in uncomplicated cases. It becomes more characteristic as the mental condition degenerates, and assumes

its typical form in the most profound state of dementia," as shown in the following sphygmographic tracing of the pulse of a patient 37 years of age. The trace given in fig. 5 shows a marked dirotic form in a patient having slight symptoms of mania. This became ir-

FIG. 5.—Trace of Dirotic Pulse in Mania.

regularly trirotic under excitement, and more regular after an outburst of excitement.—Usually the pulsating movement of the blood is not continued into the capillary vessels; but when the arteries are dilated in the glandular organs at the time of their increased functional activity, the pulsation is communicated to the capillaries, and even through them to the veins. This condition, however, lasts only during the period of increased vascular excitement; and as it subsides, the movement of the blood in the capillaries again becomes uniform, and the pulsation is limited as before to the arterial system.

PULTENEY, William, earl of Bath, an English statesman, born in 1682, died in London, July 8, 1764. He was educated at Westminster school and at Christ Church, Oxford, travelled on the continent, and in 1705 became member of parliament for the borough of Hedon in Yorkshire. This position he owed to his guardian, Henry Guy, who subsequently left him a legacy of £40,000 and landed estate to the amount of £500 a year. He acted as a whig throughout the reign of Queen Anne, participated in the prosecution of Sacheverell, and defended Walpole in the prosecution against him in 1712. When that minister resigned in 1717, Pulteney gave up his office of secretary at war, to which he had been appointed on the accession of George I. When Walpole resumed office in 1720, Pulteney was appointed cofferer of the household; but he went over to the opposition in 1725, was dismissed from his office, and became one of the most bitter enemies of the minister. He allied himself with Bolingbroke, and published pamphlets in which he attacked the ministry so virulently as to bring about a duel in 1731 between himself and Lord Hervey, in which both were slightly wounded. Through the brilliancy of his speeches, and his patriotic sentiments, he became the most popular man in the nation; and in 1742, when Walpole was driven from power, Pulteney constructed a new cabinet with the earl of Wilmington at its head, in which he took a seat, but without office, and accepted a peerage. The administration satisfied neither the people nor his partisans. Pulteney lost his popularity, and, as Chesterfield wrote, "shrunk into insignificance and an earldom." In 1746 the Pelham ministry resigned, and Pulteney became

premier; but he had so little influence that he was unable to obtain the assistance of any men of importance, and he held office only two days. In 1760 he published "A Letter to Two Great Men" (Pitt and the duke of Newcastle). As his only son had died before him, the peerage in his family became extinct.

PULTOCK, Robert, an English author, whose only known work is "The Life and Adventures of Peter Wilkins" (London, 1750), which describes an imaginary race of flying islanders in the South Pacific. The name of the author was unknown till 1835, when, at a sale of books and manuscripts which had belonged to Dodsley the publisher, the original agreement for the copyright of the book was found, in which Pultock is described as "of Clement's Inn, gentleman." He sold his story for £20, with 12 copies of the work, and a set of the first impressions of the engravings.

PULTOWA. See **POLTAVA**.

PUMA. See **COUGUAR**.

PUMICE. See **OBSIDIAN** and **PUMICE**.

PUMP, a machine for raising liquids in pipes, either by direct action or by atmospheric pressure, and also for exhausting air from vessels. (See **AIR PUMP**.) The history of the hydraulic pump cannot be clearly traced. Methods of raising water by wheels with buckets attached to their peripheries, and also by means of endless ropes moved by two drum wheels, were used by the ancient Egyptians and Assyrians; and the chain pump was probably derived from the Chinese, or at least was first used by them. But there is no evidence of the employment of a valve pump until near the commencement of the Christian era, although a machine resembling a portable pump is often represented in ancient Egyptian sculptures. Vitruvius ascribes the invention of the valve pump to Ctesibius of Alexandria, who probably lived in the latter part of the 3d century B. C. The water pump of Ctesibius was described by Heron, who flourished in the same century. It consisted of two single-acting solid-headed pistons moving up and down in two vertical cylinders with lift valves at the bottom, and a branch pipe with an outgoing valve placed between the piston and the lower valve, and was very much like the simple force pump of the present day. The motive power in large machines was an undershot paddle wheel. The employment of a valve in the piston head, and placing this below the discharge pipe, so as to constitute a lift pump, was probably of later date.—According to the manner in which pumps act, they may be divided into vacuum and force pumps; but it is more common to divide them into the force pump, the common suction pump, the lift pump, and the suction and force pump combined. The power may be applied by a piston moving to and fro in a cylinder, or by a wheel revolving in a box. Rotary pumps, in which the latter method is used, may be simply force pumps or suction and force pumps, the power being applied by direct

pressure or by centrifugal force. It is usual to denominate them rotary force pumps and centrifugal pumps. The cylinder and piston pump will be described first.—*The Force Pump.* It is probable, as has been intimated,

FIG. 1.—Force Pump.

that the earliest valve pump was a force pump, and was similar in construction and action to that shown in fig. 1 when the lower valve *v* is immersed in the reservoir, so that exhaustion, suction, or atmospheric pressure has no essential connection with its working. When the piston *P* is raised, water will rush into the chamber through *v*, and when the piston is depressed this valve will close, while the valve *w* will be raised by the water, which is forced up into the pipe *d*. Upon raising the piston again, the pressure being removed from beneath the valve *w*, the weight of water above will cause it to close and thus prevent any return. But water from external pressure will again rush through the valve *v*, and the descending piston will again force it up through the valve *w* into the discharge pipe. The operation may be continued until there is enough water in the pipe *d* to exert a pressure per square inch equal to that exerted by the propelling power upon each square inch of the piston head.—*The Common Suction Pump.* The functions of this pump depend upon the relative pressure of a column of water within the pipe and that

FIG. 2.—Common Suction Pump.

of the atmospheric pressure upon the water outside of it. At the level of the sea the pressure of the atmosphere, when water boils at 212° F., is equal to sustaining a column of mercury of 29·922 in. when at a temperature of 60°. (See *BOILING POINT*.) The atmospheric pressure is therefore capable of sustaining, under the same conditions, a column of water 33·8 ft. high,

in water and the tube completely exhausted of air, the water will rise to a height of 33·8 ft. above its level in the reservoir. The action of the common suction pump, fig. 2, will be easily understood from a consideration of this fact. The piston *P*, fitting the cylinder air-tight, on being raised will expand the air beneath it, and therefore diminish its pressure upon the water in the pipe beneath, according to the law of Boyle or Mariotte. (See *PNEUMATICS*.) When the piston is depressed the lower valve *v* will shut in consequence of the pressure being greater above than below, and the valve in the piston, opening upward, will open when the density of the air in the cylinder becomes greater than that of the external air, and its contents will thus be expelled. Succeeding motions of the piston will thus continue to exhaust the air within the pipe until the pressure of the air on the water in the reservoir is sufficient to force the water in the pump up to the lower or suction valve. If the exhaustion is complete the water will rise to a height of 33·8 ft. This effect can be secured by filling the pump with water at the top before commencing. Now, as a column of water 33·8 ft. high ordinarily measures the extent of the pressure of the atmosphere at the level of the sea, it follows that if the suction valve is placed at a greater distance above the water in the reservoir the pump will not work. At an elevation, as upon the side or top of a mountain, the atmospheric pressure being less, the valve must be placed lower. At a height of 15,700 ft., where water boils at about 186° and the barometer stands at about 17·5 inches, the lower valve requires to be within 19·7 ft. above the level of the water in the reservoir, this being the height of a column of water which will balance the atmospheric column.—*The Lift Pump.* By a slight change in the form of the suction pump, and the addition of a valve at *x*, fig. 3, the modern form of the lift pump is produced, and the water may be raised to a height corresponding to the amount of power applied. The form shown in this figure is that of a lift and suction pump combined. Removing the lower valve *v*, and immersing the pump till the valve *w* in the piston is below the surface of the external water, the machine becomes simply a lift pump. The suction pump is also often called a lift pump. A form which is often figured in books employs an exterior frame supporting a piston rod which enters the pump at the lower end, pushing the piston

FIG. 3.—Lift Pump.

or a little more than 13½ times as high as the column of mercury, the specific gravity of the fluid metal being 13·557 at 62·6° F. (See *MERCURY*.) Consequently, if the lower end of a vertical tube of sufficient length is immersed

up instead of raising it through a packed box at the top of the cylinder. Such were the old pumps used by Rannequin in the water works at Marli, and by Lintlaer in the engines erected during the reign of Henry IV. at the Pont

Neuf, to supply the Louvre from the Seine. The lift pump is in fact another kind of force pump, and in its simplest form may have been one of the first employed. The efficiency of the force pump, as well as of the lift pump, may be greatly increased by the employment of an air chamber, as shown in fig. 4, by which means a constant and equable flow is secured and the sudden

FIG. 4.—Force Pump with Air Chamber.

shock of reaction avoided. A dome-shaped vessel is placed in the course of the discharge pipe, a short distance beyond the upper valve. When the water in the discharge pipe is raised to a height of 33·8 ft. above the level of the water in the air chamber, the latter will of course be half filled with water, the air being compressed to one half its original volume by the double pressure of water and atmospheric air upon it. It may be remarked that, as in the case of the hydraulic ram, the air in the chamber becomes gradually absorbed by the water as it passes through the pump, and must from time to time be replaced. The discharge pipe, instead of branching off from the base of the air chamber, may pass directly into it through a hole in the dome, and down to near the base. In either case the air chamber is replenished by allowing the water to run off by a cock at its base. A double-acting force pump is shown in fig. 5. This possesses the advantage of producing a more uninterrupted stream than the form shown in fig. 1, and if supplied with an air chamber the latter need

FIG. 5.—Double-Acting Force Pump.

not be so large to effect the same equalization of current. Double-acting force pumps, either with or without the air chamber, are often employed at large town water works for raising water to the distributing reservoirs.

Such a pump acts as follows. When the solid piston head P descends, the valves *a* and *e* are forced shut, while *d* and *c* are opened, water entering behind the piston through *d* and being forced in front of it through *c*, and up the pipe CD. When the piston is raised the position of the valves is reversed,

the water entering through *a* and being forced out through *e*. This is the position shown in the figure. When water is to be raised to a great height or against great resistance, as in the hydrostatic or hydraulic press, a plunger in place of the ordinary piston with packed head is used, which passes through a tightly packed box, as shown in fig. 6. Such plunger pumps were employed in the water works at York buildings, London,

FIG. 6.—Plunger Pump.

in the last century, but they are described in Commandine's translation of Heron's *Spiritalia*. It is evident that the introduction of the plunger into the cylinder must expel an equal volume of water through the upper valve, and on being withdrawn allow the entrance of the same quantity through the lower valve. The fire engine is a combination of two force pumps, as shown in fig. 7, the water being forced from each into the common air chamber A, and so on through the discharge pipe E, to which may be attached the hose. The power applied as a motor may be various, as that of man, of animals, of water, or of steam. The earliest application of a steam engine to a pump was by Newcomen in 1713. The contrivance of Savary can hardly be called an application of a steam engine to a pump, because the steam cylinder was a part of the pump itself, the steam performing the functions of a piston head. Very large pumps are often used for drainage purposes, which are usually worked by steam engines separate from the pump itself. An enormous steam engine was employed in the drainage of Haarlem lake in Holland, which

FIG. 7.—Fire Engine.

drove ten pumps having a united capacity of raising 112 tons of water at each stroke. (See DRAINAGE.) Large pumps are used for raising water into reservoirs for supplying cities. (See WATER WORKS.) Most modern pumps

of moderate size which are driven by steam are known as direct-acting steam pumps; that is, there is no intervention of rotary motion, the reciprocating motion not being caused by the action of an eccentric, and the dead points or centres are avoided by the use of what is called an auxiliary valve. A good steam pump of this kind, constructed by the "Knowles Steam Pump Works" of Warren, Mass., a company owning the patent for the auxiliary valve, is shown in fig. 8. The auxiliary valve, A, moves back and forth within the steam chest, and it also has a slight rotary motion by which the ports at each end are opened and shut to produce reciprocating motion. When steam is admitted into the steam chest, it enters the valve A at the middle portion and passes out at one of the ports of the main flat valve v , this valve being moved over its seat by the motion of the auxiliary valve, through the medium of the stem S, which plays in a slot wide enough to admit of the slight rotation of the auxiliary valve. Now, when the steam enters the cylinder C, we will suppose upon the left, the piston is driven in the direction G D. This carries the standard F in the same direction. In the top of this standard there is a hole which slides over the rod $d' d''$, upon which there are two cams, w and o . When the top of the standard strikes one of these, it pushes the rod $d' d''$ which is attached to the auxiliary valve A in one direction, and also rotates it sufficiently to reverse the ports in the steam chest. The main valve v is therefore reversed and steam is admitted upon the other side of the piston head, by which means the standard F is moved in the direction opposite to its previous one, so that it will strike the opposite cam and cause

into French mines by Belidor in 1739, and is described in his *Architecture hydraulique*. It consists of two cylinders, a larger, C, fig. 9, and a smaller, D, with a piston in each, connected by a common rod. A supply pipe, A, conveys the descending column from its source

FIG. 9.—Hydraulic Pressure Engine, from Belidor.

to the three-way cock F, the air chamber E and the pipe B being the way of exit for that portion of the water which is raised. When the water from A enters the way leading into C, the piston in this cylinder, having, we will suppose, twice the area of cross section as the one in D, will force the water from the latter up the pipe B at each stroke until it has twice the elevation of the source supplying A. The three-way cock is so arranged that the pipe A is connected with the cylinder C or with the pipe H, and through it with the cylinder D by means of connections between the piston rod and a set of levers. When the piston in C returns toward F, an opening at one side of the three-way cock allows the water to escape,

the opening being closed when the piston begins to move in the direction of D. A portion of the water therefore runs to waste, a necessary result of the laws of mechanics.—*Rotary Pumps*. These are of two kinds, force pumps proper and centrifugal pumps. One of the oldest forms of rotary force pumps of which there is an account was contained in a collection of old models by Servière, born at Lyons in 1593. It consists of two cog wheels within an elliptical box, fitting accurately, as shown in fig. 10. It will be readily seen that the water must be propelled in the direction taken by the cogs which are in contact with the box. The cogs, fitting to each other accurately in the centre of the box, prevent the return of water, and the machine

FIG. 8.—Knowles's Steam Pump.

the rod $d' d''$ to move forward and rotate and again reverse the auxiliary valve A. The pump is simply a double-acting force pump with an air chamber, and its action needs no special explanation. A force pump called a hydraulic pressure engine was devised and introduced

becomes both a force and a suction pump. When accurately made and used only in clear water, it is quite an efficient machine, and has since been employed as a form of rotary steam engine. It could not be used to raise water containing gravel or much solid matter. An-

Fig. 10.—Rotary Pump from Servière's collection.

Fig. 11.—Rotary Pump of 16th century.

other old form of rotary pump of the 16th century is shown in fig. 11. A wheel of a diameter and thickness proportional to the capacity of the pump has its periphery formed into three cams, which give space for the passage of water between them and the inner surface of the cylindrical box in which it moves, and also raise and drop a broad sliding vertical bar, B (seen edgewise), which acts as a shut-off to the passage of the water within the box, directing it into the pipe A. The cams act the part of pistons, the water entering at the bottom of the cylinder and being forced in the direction of the arrows. To prevent its return on stopping the pump, a lift valve is placed in the discharge pipe, which shuts when the pressure above exceeds that below it. There are many other and recent forms of rotary force pumps, acting much upon the same principles, with the addition of devices which se-

Fig. 12.

Fig. 13.

Bagley and Sewall's Rotary Pump.

cure greater efficiency. One of the latest of these is Bagley and Sewall's, patented by L. D. Green, of which fig. 12 is a vertical longitudinal, and fig. 13 a transverse section. A is the main case, made in one piece, and having attached the ring B, seen in both sections. The

space outside of B is the water space. This cylinder is enclosed by the disk D, which is attached to the shaft. An eccentric ring, E, is attached to the disk D so that in revolving its outer surface touches the inside of the case A, while the interior surface upon the opposite side of the ring touches the outside of the ring B. The eccentric ring E acts as the piston of the pump. The suction and discharge are respectively shown in both sections at I and J, the direction of the water being indicated in fig. 12 by the arrows. The parts are separated by the sliding valve H H, which is moved back and forth on its seat by means of two tumblers shown in fig. 13 between H and H. These tumblers are moved by the eccentric ring E, which passes between them. The centre ring B is made enough deeper than the casing A, as shown in fig. 12, to equalize the quantity of water within and without the eccentric piston ring E. F is the cover or outside case, and contains a closed bearing for the end of the shaft. The inner part of the disk D forms a collar G to the shaft, and by means of a screw at the end this collar can be forced tightly against its seat K, thus avoiding the use of packing. In the centre of the seat there is a circular groove, shown in section at K K, which connects by a drilled channel with the suction part. Any tendency to escape of water at the seat by pressure is thus overcome by vacuum force.—The chain pump consists of an endless chain carrying cups or disks around two drums, one beneath the surface of the water in the well or stream, and the other at a convenient elevation. The ascending part of the chain passes through a pipe just large enough to allow the cups or disks, which act as pistons, to move with little friction. It will thus be seen that the chain pump is little else

Fig. 14.—Old French Chain Pump.

than a modified form of rotary pump. When the water is to be raised to a moderate height, it often becomes a convenient and useful machine. Fig. 14 shows the form of an old French chain pump used in the ship yards at Marseilles, described by Belidor. It was worked

by two galley slaves, who were relieved every hour. It is uncertain where the chain pump originated, but it was probably first used in China in the form of an inclined trough with drums at either end, giving motion to a chain or rope with scoops or blocks attached.—The centrifugal pump is a machine which acts upon an entirely different principle from that of any pump so far described. The force which elevates the water is the centrifugal force developed by the revolution of a fan

FIG. 15.—Massachusetts Pump.

wheel. An early efficient form of centrifugal pumps was constructed in Massachusetts in 1818, and called the Massachusetts pump. It resembles an ordinary fan blower, as will be seen by the cut, fig. 15. It consists of a horizontal shaft to which are attached four eccentric blades, narrowed toward their extremities and located within a cylindrical-shaped box, from which a discharge pipe F passes upward. The water is received at the centre, around the shaft, which is so placed that the blades just graze the inner surface of the box at the junction of the discharge pipe, into which the water is necessarily forced. The apparatus is placed below the level of the water, as the vacuum power is small. A more recent form of centrifugal pump is Appold's, shown in figs. 16 and 17, which was first exhibited at the world's fair in London in 1851. The efficiency of a centrifugal pump depends upon the form of its blades, and Mr. Appold made a great improvement, nearly doubling the efficiency of the Massachusetts pump, by giving them the form shown in section by the dotted lines in fig. 17. The revolving fan wheel, shown in fig. 16 at c, is fixed

FIG. 16.

Appold's Centrifugal Pump.

FIG. 17.

to the end of a shaft turned by the drum D. It plays between two circular checks, through the centre of both of which there is a circular opening to admit the water from the reservoir, beneath the level of which the wheel is placed. The water enters at the central part of the fan, as shown in section in fig. 16 by the four curved arrows, two on either side,

the whole being rotated in the contrary direction. The lower part of the discharge pipe is enlarged into a drum somewhat similar to that of the Massachusetts and of the Gwynne pump, and the water issues from all parts of the periphery of the fan wheel and is forced upward into the discharge pipe A. Calculations have been made as to the height to which water may be carried with one of these pumps, but they do not possess much practical value, as the power of each machine varies with its construction; and 20 ft. is the practical limit, although by means of a very high velocity, not practicable for ordinary use, a height of 50 ft. has been reached. Gwynne and co.'s centrifugal pump is a modification of Appold's, and was shown at the same exhibition. A sectional view is given in fig. 18. Six equidistant arms, extending first in the direction of radii, but toward their outer ends curved and pointing backward as regards the direction of rotation, are fixed within a drum, which again moves within an outer drum.

The water enters at the centre, and taking the course of the arrows ascends the discharge pipe. Three of the arms commence at the axis, but the other three, alternating, commence at the circle of admission. The two drums are only in contact at a small ring surrounding the central opening. The arms diminish in breadth toward their outer extremities

FIG. 18.—Gwynne's Centrifugal Pump.

to render the flow of water smooth, as the increase of centrifugal force at the periphery causes an increase in the velocity of the water, and therefore it requires a less space through which to move.—There are numerous practical points about the different kinds of pumps, to mention which would require a too extended detail. It may be remarked that a pump is one of the most difficult machines to keep in order. It is exposed, if not constantly in use, to great changes of moisture and dryness, and its metallic parts, particularly if of iron, soon become rusty. It is often convenient to have valves partly made of leather, but these cannot be expected to last long; if constantly in use they soon wear out, and if they are allowed to become dry they shrink and cease to perform their offices well.—A kind of steam pump without a piston, called a "pulsometer," is the invention of Mr. C. H. Hall of New York. It consists of two long-necked chambers joined together at the top, where a ball valve by falling one way or the other opens one of the chambers to the admission of steam. The water is admitted at the bottom of the chambers, and passes into

them alternately through two openings, which are also opened and closed by ball valves, the alternate expansion and condensation of steam in the chambers causing the movements. A delivery passage, common to both chambers, is also provided with a ball valve, which oscillates from side to side as the lower valves alternately open and close. It is claimed to be peculiarly adapted to pumping water from mines, from its not being liable to get out of order, working very well, it is said, when the water contains grit and mud.—Pumps for ships, mines, and submarine excavations, from their liability to become obstructed with solid substances or corroded with salt water, should be selected with especial reference to the difficulties met with in each case. The valves should be constructed in such a manner that they will not be liable to become clogged, and, when they are so, can be easily reached and cleaned.—For a further description of pumps and water engines, see Ewbank's "Hydraulics" (new ed., New York, 1863), the report on the Paris universal exposition of 1867 by F. A. P. Barnard, LL. D. (New York, 1869), and Spon's "Dictionary of Engineering" (London, 1874).

PUMPELLY, Raphael, an American metallurgist, born at Owego, N. Y., Sept. 8, 1837. He studied for several years in Hanover, Paris, and Freiberg in Saxony, returning home in 1860. He afterward engaged in mining and smelting operations in Arizona and other territories, and was employed by the Japanese government to explore the mineral resources of the island of Yezo, and by the Chinese government to survey the coal fields of northern China. In 1866 he was appointed professor of mining engineering in Harvard university, in 1870-'71 had charge of the state geological survey of the copper district of Michigan, and in 1871 was appointed state geologist of Missouri, which post he resigned in 1873. He has published "Across America and Asia" (New York, 1870); "Geological Survey of Missouri, Preliminary Report," with an atlas and plates (1873); "Geological Survey of Michigan," vol. i., part 2, "Copper District," with atlas (1873); and various monographs in scientific journals.

PUMPKIN (formerly written pompion, from the old French *pompon*; Gr. *πέπων*), the plant and fruit of *cucurbita pepo*, an annual plant of the natural order *cucurbitaceæ* or gourd family, for the characters of which see **GOURD**. The genus *cucurbita* has large yellow flowers, with a bell-shaped or short funnel-formed, five-cleft corolla, its base adherent to the bell-shaped tube of the calyx; the three long, much curved anthers united into a small head; stigmas three, each three-lobed; fruit fleshy, with a firm rind. The pumpkins, the squashes in all their great variety, and the vegetable marrows belong to this genus, in which the species are in great confusion. The term pumpkin is in different parts of the country very loosely ap-

plied; in the present article it refers to those varieties of *C. pepo* which are known in the agriculture of the northern states as pumpkin, leaving the others to be described under **SQUASH**. The plant is a vigorous one, often running 12 ft. or more; rough-hairy, and almost prickly;

Field Pumpkin (*Cucurbita pepo*).

the flower stalks are obtusely angled, and after fruiting have five to eight ridges with deep grooves between; the fruit varies in shape, and is marked with longitudinal broad ribs and furrows; the interior is hollow, and traversed by coarse pulpy threads. In its most common form the fruit is a little longer than broad, flattened at the ends, and rather regularly ribbed, and averaging about a foot in diameter, though often much larger; the color a rich clear orange yellow. There is much doubt as to the native country of the pumpkin, it being claimed for the Levant and for Astrakhan, while Dr. Gray ("American Journal of Science," 1857) shows that there is good reason for believing it to have been cultivated in this country by the Indians before the coming of the whites. In the earlier agriculture of the country the pumpkin was a more important crop than at present; it was then raised, as it is now to some extent, as a "stolen crop," a few seeds placed at intervals in a field of Indian corn or potatoes often giving, besides the regular crop, a ton of pumpkins, which afforded a food much relished by cattle, and abundant supplies for the table. Before the introduction of the greatly superior squashes, or even the better varieties of the pumpkin, the common field variety was much used as food, not only as the basis of pumpkin pies, but for a table vegetable, as squash is now served; stewed or baked pumpkin (the fruit divided, the seeds and stringy matter removed, and the halves baked) was a very common article of food, and is still preferred by some to the finer substitutes. For winter use it is cut into thin strips and dried in the sun, or in a warm room. Its use is at present mainly for feeding farm animals, for which purpose the seeds must be removed, as they have a diuretic effect, which is especially undesirable for milking cows. The

best variety for table use is the sugar pumpkin, which, though not large, is an abundant bearer; it has a very long stalk, is of a bright orange color, and has a fine-grained, sweet flesh. Another esteemed variety is the cheese pumpkin, so called from its shape; it is large, and of a deep reddish orange color. The long pumpkin is twice as long as broad; the striped is like the common field pumpkin, but marked with alternate bands of green and yellow, while the Nantucket is deep green when ripe, and a little yellowish on the sunny side, while its surface is marked by warty excrescences; this is much esteemed for its good quality and long keeping. The flesh of the pumpkin contains much sugar, and it is said that during the war of independence housekeepers boiled it in water and evaporated the decoction to a sirup, as a substitute for sugar. Besides the diuretic property already referred to, the seeds are among the most valued anthelmintics for the removal of tapeworm; though this property was ascribed to them a long while ago, they have only recently come into very general use. Dr. Patterson of Philadelphia about 20 years ago published an account of a remarkable cure by their use, followed in an hour and a half by castor oil. The dose of the seeds is two ounces; they are first deprived of their coats, and the kernels beaten in a mortar to a paste, to which water is gradually added.

PUNCH, or **Panchinello**, a humorous character in a species of puppet show exhibited in the streets of European cities. The exhibition is of Italian origin, and its Italian name *Polcinella* or *Puleinella*, according to Gallani in his *Vocabolario del dialetto Napoletano*, was derived from Puccio d'Aniello, a buffoon of Acerra, near Naples, whose humorous eccentricities were in the 17th century transferred to the Neapolitan stage; and the character continues to be the medium of local and political satire in the Italian exhibitions of *fantoccini*, or puppet shows. Another theory derives the name from *pollice*, thumb, a name of dwarfs in several languages. It is thought that the grotesque face is only a modification of the ancient comic mask, and that the character of Punch is kindred to the "Vice" of the old moralities, and the clown of the later drama. The modern drama of "Punch" is supposed to have been composed by Silvio Fiorello, an Italian comedian, about 1600. It embodies a domestic tragedy followed by a supernatural retribution, the whole of which is treated in a broadly farcical manner. Punch is a short obese personage, with an enormous hump on his back, a wide mouth, long chin, and hooked nose, and wearing a three-pointed cap. His wife Judy and his dog Toby are important characters in the performance. A similar puppet show, containing the same leading characters, has been known for ages in China. It is managed by a single individual, who exhibits the theatre on his head, the moving wires being concealed under his gown.

PUNCTUATION, in grammar, the art of dividing a written or printed discourse into sentences and parts of sentences, for the purpose of indicating the mutual relations of the words, by means of points. The principal points used in English composition are the comma (,), semicolon (;), colon (:), period (.), note of interrogation (?), note of exclamation or admiration (!), dash (—), and parenthesis (). Of these, only the first four are marks of punctuation as the term is usually understood, or grammatical points indicating the length and character of the pauses to be made in reading. The others are mainly rhetorical or syntactical aids, regulating the modulation of the tone rather than the suspension of the voice; but the interrogation or exclamation point may take the place of either of the former, according to the structure of the sentence, and the dash partakes of both characteristics. The comma marks the smallest grammatical division in written or printed language. The semicolon separates such parts of a sentence as are somewhat less closely connected than those separated by a comma. The colon denotes a still longer pause than the semicolon. The period indicates the end of an assertive sentence which is grammatically independent of any that follows, and is also used after every abbreviated word, after headings, titles of books, &c., and generally (though improperly) after Roman numerals. The note of interrogation is placed after a question, and in Spanish is also placed inverted at the beginning of a question. The note of exclamation indicates an ardent wish, admiration, or other strong emotion, and is placed after interjections, words used as interjections, and clauses or sentences expressing strong emotion of any kind; it is also duplicated in Spanish like the preceding. The dash is employed where a sentence breaks off abruptly and the subject is changed; where the sense is suspended, and is continued after a short interruption; where there is an unexpected or epigrammatic turn in the sentiment; after a long member, or series of phrases or clauses, leading to an important conclusion; before a word or phrase repeated in an exclamatory or emphatic manner—what elocutionists term an echo; where there is an ellipsis of such words as "namely" and "that is;" where there is an ellipsis of letters or figures; and in numerous other cases. Sometimes, as in this work, it is used instead of paragraphs. The parenthesis encloses a word or phrase introduced into the body of a sentence with which it has no grammatical connection, or an explanatory or other sentence or passage independent of the context.—Other marks in frequent use, and generally treated under the head of punctuation, though not strictly included in it, are the apostrophe ('), used to indicate the omission of a letter or letters, and also as a sign of the possessive case; the hyphen (-), placed between the constituent parts of a compound word, and at the end of a line when a word is divided; quotation marks

(" or '), placed at the beginning and end of extracted passages, of the speeches in dialogue, &c.; brackets or crotchets [], generally enclosing an explanatory phrase or passage inserted by one writer in a quotation from another; and references (consisting of the characters *, †, ‡, §, ||, and ¶, called respectively asterisk or star, dagger, double dagger, section, parallel, and paragraph, or of figures or letters smaller than those of the text), pointing to notes correspondingly marked at the foot or margin of the page.—The ancients were in the habit of writing without distinction of either sentences or words until about 364 B. C. Afterward it became usual to place a mark of distinction at the end of every word, as in the following inscription found near Bath, England:

IVLIVS VITALIS FABRI, &c.

Sometimes, as in the subjoined extract from an inscription given by Montfaucon, a letter laid horizontally was used as an interstitial mark:

P. FERRARIUS HERMES
CAECINIAE ⇨ DIGNAE
CONIVGI ⇨ KARISSIMAE
NYMERIAE ⇨

But there is reason to believe that some system of punctuation was known to the Greeks in the time of Aristotle. It probably consisted of a single mark, which changed its significance according to a change of position. At the bottom of a letter (A.) it was equivalent to a comma; in the middle (A-) to a colon; and at the top (A') to a period; but this plan could only be followed as long as Greek manuscripts were written entirely in capitals. St. Jerome in his translation of the Scriptures used certain marks of distinction or division, which he called *commata* and *cola*; but it has been thought that they consisted simply in writing every clause on a separate line. The modern points came into use very gradually after the invention of printing, the comma, parenthesis, note of interrogation, and period being the earliest introduced, and the note of exclamation the last. The first printed books have only arbitrary marks here and there, and it was not until the 16th century that an approach was made to a regular system by the Manutii of Venice.

PUNJAUB, or **Panjab** (Pers., the country of the five rivers), a province in the N. W. portion of British India, between lat. 27° 40' and 35° 5' N., and lon. 69° 30' and 78° 30' E., and bounded N. by Kafiristan and Cashmere, E. by the Himalaya range and Northwest Provinces, S. by Rajpootana and Bhawalpoor, S. W. by Sind, and W. by Beloochistan and Afghanistan. According to the official statement of the progress and condition of India submitted to the British parliament in June, 1874, the area of the Punjab is 103,748 sq. m., evidently including the Bannu district, which was omitted in the statement of the previous year. (See INDIA.) According to the last census, taken in January, 1868, the population was more than 17,500,000, but is supposed now to

have increased to 19,000,000. There are ten civil divisions, each under a commissioner, and subdivided into districts as follows: 1. Ambala or Umballa—Ambala, Loodiana, Simla. 2. Amritsir—Amritsir, Gurdaspoor, Sealkote. 3. Delhi—Delhi, Goorgaon, Kurnal. 4. Dera-jat—Bunnoo or Bannu, Dera Ghazi Khan, Dera Ismail Khan. 5. Hissar—Hissar, Rohtuk, Sirsa. 6. Jalandhar—Hoshiarpoor, Jalandhar, Kangra. 7. Lahore—Ferozepoor, Gujranwala, Lahore. 8. Mooltan—Jhang, Montgomery, Mooltan, Mozuffergurh. 9. Peshawer—Huzara (Abbottabad), Kohat, Peshawer. 10. Rawulpindi—Gujrat, Jhylum, Rawulpindi, Shahpoor. Under the supervision of the Punjab government are 32 native Himalayan hill states, of which Cashmere is by far the most important. (See CASHMERE.) Of these, five in addition to Cashmere are beyond the river Sutlej; among them Chumba, area 3,216 sq. m., pop. 110,000, paying an annual tribute of £500; Mandi, area 1,080 sq. m., pop. 135,000, annual tribute £10,000; and Sukhet, area 420 sq. m., pop. 45,000, annual tribute £1,100. The remaining 26 hill states lie S. of the Sutlej, and are geographically arranged into four groups, known as the northern, east central, west central, and southern groups. Each of these states is very small, the most important being Nahun or Sirmor, in the southern group, whose sovereign has 90,000 subjects. The affairs of the native state of Bhawalpoor are managed by a British political agent, whose administration is supervised by the lieutenant governor of the Punjab.—The territory of the Punjab is exceedingly irregular in outline, but consists mainly of the extensive plain which slopes S. W. from the highlands of Cashmere. This plain is drained by the Indus, and its five great tributaries, from which the country derives its name, though some geographers improperly regard it as derived from the Indus and its four larger tributaries, excluding the Beas. The Indus is the westernmost river; the tributaries, from W. to E., are the Jhylum, the Chenaub, the Ravee, the Sutlej, and the affluent of the latter, the Beas, all flowing into the Indus near Mittun Kote, lat. 28° 58' N., lon. 70° 23' E., through the Punjnad, a broad stream in which their waters unite about 50 m. N. E. of this point of confluence. The Punjnad is formed by the union of the Chenaub from the north, bearing the accumulated waters of the Jhylum and the Ravee, with the Ghara, or united Sutlej and Beas, from the east. These streams are all described under their own names. The only portion of the Punjab not included in the Indus basin is the region about Delhi bordering the Northwest Provinces, which lie within the valley of the Ganges.—The mountains of the Punjab are confined to the N. E. and N. W. corners of the province. In the former region is the Himalayan district of Kangra, comprising Lahool, Spiti, and Kulo; and in the latter the Salt range, about 2,000 ft. high, trends westward from the Jhylum

and crosses the Indus, beyond which it is known as the Kalabagh and extends to the Suleiman or Solyman mountains in Afghanistan. The general aspect of the districts of the Punjab N. of the Salt range is hilly and even mountainous. The elevation of the great plain at the foot of the mountains, however, is only about 1,000 ft., and thence the surface slopes gradually southward, diversified by scarcely an eminence, until it is little more than 200 ft. above the level of the sea in the southern part of the province, where the country is for the most part an absolute desert.—The plain is divided into five extensive doabs, as the natives term the spaces enclosed between the convergent rivers. Enumerated from W. to E., these doabs are: 1, the Sindh Sagur doab, the largest of all, between the Indus on the west and the Jhylum, Chenaub, and Punj-nud on the east; 2, the Jetch, between the Jhylum and the Chenaub; 3, the Richna, between the Chenaub and the Ravee; 4, the Baree, which is the most densely populated and prosperous, between the Ravee and Chenaub and the Ghara; and 5, the Jalandhar, between the Beas and the Sutlej. Fertility is diffused over the narrow plain along the base of the Himalaya range by the six rivers which there first enter upon it, and the abundant rainfall of not less than 40 inches in the year to which it is subject. Here artificial irrigation is needless. In the northern dry zone, a strip of country below this, from 100 to 200 m. broad, and where the annual supply of rain is between 15 and 30 inches, the rivers have worn down their valleys to a level from 10 to 50 ft. lower than the general surface of the plain. The width of these valleys varies from 4 to 10 m., and they contain the fertile tracts of this portion of the province, called Khadar lands. Their borders are the loftier sterile expanses of the plateau, known as Bangar lands and forming the doabs. These are largely overgrown with grass and brushwood, and though they are fertile, cultivation is dependent upon an artificial supply of water. Near the confluence of the rivers the Khadar lowlands extend from stream to stream and the high tracts disappear; but the aridity of the climate in this region is such that the rivers alone do not suffice to maintain the productiveness even of their valleys, and without artificial irrigation the adjacent country would be a mere waste. Frequent changes occur in the course of each of the great rivers of the Punjab, and from October, when the Indus is lowest, until spring-time, its capacious bed is occupied by a number of shallow watercourses hardly navigable. In the plains the periodical rise of the river begins in February, when the melted snows of the Himalaya begin to come down, and its volume increases till July, when the river is in full flood.—Three kinds of irrigation are practised in the Punjab. In the Himalayan districts and elsewhere in the north, where water is less than 25 ft. from the surface, the

supply for agricultural and horticultural purposes is obtained from wells. A system of irrigation through inundation canals, whereby the water is conducted from the rivers when they are highest, is applied in the comparatively rainless districts wherever the land is low enough. The inundation system comprises the canals of the lower Sutlej and Chenaub division, 39 in number and 632 m. in length, which water the garden-like district of Mooltan; the upper Sutlej canals above Mooltan, 213 m. long; and the Indus canals, of which 600 m. are in the district of Derajat on the right bank of the river, and 66 m. in Mozufgerh on the left. The inundation system, however, was not applicable to the higher lands of the doabs, which require perennial canals to make their natural fertility available. This want has been supplied only to the upper portion of the Baree doab, which is traversed by a canal from the Ravee at Madhpoor, where that river leaves the Himalaya, extending in three branches to Lahore, Kussoor, and Sohraon. In 1872-'3 the main channel of this state canal was 212 m. long, with 692 m. of distributaries, watering 228,796 acres. All the canals are managed by the government irrigation department.—The climate of the plains is dry and exceedingly warm. In the colder season the midday temperature is seldom below 70° F., and not infrequently 80°, while in summer it sometimes rises to 112° in the shade. In the higher northern districts the climate is proportionately cooler.—The flora of the province is not abundant or varied. Characteristic forms of vegetation are acacias, tamarisks, a tree-like caper without leaves, the jujube, and a species of wild palm. There is a great deficiency of timber. The government leases and manages the deodar forests in the native tributary states of the Trans-Sutlej highlands, where this valuable tree grows only at a height of from 5,000 to 9,000 ft. The valleys of all the principal rivers also contain forests of deodar. The Indus is bordered by babul forests in the arid districts of the south near Sinde. In the doabs of the dry region are tracts of wood and jungle called rakhs, from which considerable fuel is obtained, and the management of which, to the extent of about 8,000 sq. m., has recently been undertaken by the forest department. The collection of waif and drift timber on the rivers is regulated by law. In 1872-'3 the receipts from the government forests were but £65,300, against an expenditure of £79,594 upon them. Earnest efforts are being made to promote the growth of forest trees, and the forest administration has established several tree plantations, one of them on the Bari doab canal covering 7,200 acres. Fruit is grown in the vicinity of the towns and villages, the mangoes, oranges, and pomegranates of Mooltan being especially noted for their excellent quality; almonds, figs, mulberries, dates, apricots, peaches, apples, quinces, and melons are also raised. At Lahore there

is an agri-horticultural society, through whose efforts the olive and the Australian blue gum tree (*eucalyptus globulus*) have been introduced into the province.—The tiger is the most formidable of the wild animals found in the Punjab. The lion has sometimes been enumerated among the carnivora of the region, but probably does not now exist in India except within or near the peninsula of Guzerat. The leopard and wild cat commit annoying depredations on the smaller domestic animals. Lynxes, wolves, hyenas, jackals, porcupines, foxes, and hares are common. A species of black bear (*helarctos tibetanus*) is met with in the Salt range, where also the wild pig is distributed in large numbers. Several species of deer and antelopes inhabit the province, and wild sheep, sometimes called deer-sheep on account of their shy habits and fleetness, are numerous in many districts. The fauna of the Punjab is particularly rich in birds, among which are the Asiatic bald-headed eagle, the pea fowl and common jungle fowl, parrots, kites, ravens, jackdaws, owls, pigeons, pheasants, partridges, quails, and many kinds of water fowl, including geese, ducks, herons, cormorants, pelicans, and the black ibis. The Indian alligator haunts the rivers, which abound in many varieties of excellent fish. Fish is extensively eaten by the people.—The principal mineral product is rock salt, which occurs on the S. side of the Salt range in deposits said to be unsurpassed elsewhere in the world in extent or purity. It is mined from considerable depths and also quarried at the surface, and there are at least 12 localities in the range at which vast deposits are known to exist. Salt of a black or dark green hue is quarried in the hills of the Kohat district. Small quantities of gold, quite insignificant in proportion to the labor required to obtain them, can be washed from the gravel of many of the streams. Petroleum has been discovered at Rawalpindi and elsewhere, but has not yet been put to any practical use.—Among the more important agricultural products are wheat, sugar, rice, barley, millet, maize, peas, beans, mustard, and hemp and other fibres. In 1872-'3, 47,781 acres were planted with *crotalaria juncea*, a leguminous annual yielding the fibre known as sunn, from which twine is made. Tobacco was grown on 90,000 acres, and 7,732 acres are included within the 28 tea plantations of the Kangra district, where the average yield is 130 lbs. per acre. The crop of 1872 amounted to 428,655 lbs. The breeding of horses is encouraged by the government, which keeps 37 stallions in the province. An important horse fair is annually held at Rawalpindi for market purposes as well as the distribution of government prizes. There are also great cattle fairs at Hissar and Sirsa, sometimes attended by more than 25,000 persons. Sheep are raised in the grazing districts from English imported stock.—The manufactures of the province, valued at £5,315,400 in 1872-'3, consist largely of cotton, which is

made into white and colored cloths and thick striped cloth for floors; woollen goods, from the fleeces of sheep, goats, and camels; and silk made at Amritsir, Lahore, and Mooltan, out of the raw material imported from Bengal, China, Afghanistan, and eastern Turkistan. The industrial progress of the country is actively stimulated by the numerous fairs frequently held in various localities. Of these there are 128 in the Punjab, each attended by at least 10,000 persons, and some by more than 100,000. In the year 1872-'3 the value of the trade up the Indus was £47,588, against a downward trade of £448,476, while the external trade of the province amounted to £5,024,883.—According to the parliamentary accounts for 1872-'3, there were in that year 410 m. of railway in the Punjab, 2,470 m. of water communication, and 20,798 m. of roads. The railway system is not yet completed. At present there is the great trunk road from Delhi to Lahore and thence to Mooltan, whence the broad gauge Indus valley line, 480 m. in length, now in process of construction, will run southward to Kotree and there meet the Sindh railway from Kurrachee. Lahore is also to be connected with Peshawer by a narrow gauge line, 270 m. long, with three costly bridges over the Ravee, Chenuab, and Jhylum rivers. Lines of telegraph are already in existence along all these routes.—The ancient village communities have maintained their organization intact throughout a great part of the Punjab, and the proprietors of the soil usually cultivate it themselves, paying the land tax through the elders of their village. Otherwise the land settlement is like that of the Northwest Provinces. The revenue derived from it is easily collected, and in 1872-'3 amounted to £2,005,666. A revenue of £811,190 was derived from the sale of salt and the duties on that mineral collected at the customs line, 982 m. long, which runs down the Indus, and is intended to restrict the importation of red salt from Peshawer. The opium excise and licenses for the sale of drugs and spirits yielded £87,633. In the same year, under a new arrangement, the local authorities received £748,718 from the supreme government of India for provincial expenditure upon jails, police, education, hospitals, roads, buildings, miscellaneous public improvements, and other objects of a local character; and the disbursements out of provincial funds amounted to £515,153. The local revenue in that year was £751,040, and the local expenditure £468,174. Municipal institutions for local taxation and expenditure have been organized by the British government in 125 cities and towns, and 189 smaller places; a few of the more important municipalities elect their own officers.—The population of the Punjab is made up of Mahomedans and Hindoos in the proportion of about two to one. The Sikhs constitute about half of the smaller and Hindoo portion. The total number of native Protestant converts to

Christianity in the province in 1872 was 1,870, of whom 14 were ordained ministers, and 707 were communicants. There are two colleges in the Punjaub affiliated to the university of Calcutta: one at Lahore, with 52 students in 1872-'3; the other at Delhi, attended by 36 students. The government maintains three normal schools and aids six others; of high schools it supports six and assists ten. There is a special educational institution at Ambala for instructing the wards of the government and the sons of natives of rank; and the government also manages an Anglo-Arabic school at Delhi endowed by a native nawaub. The entire number of government primary or village schools in the province is 1,046, having an average daily attendance of 51,251 pupils, in addition to which there are 188 aided schools of the same class with an average attendance of 20,825. There are 345 schools for girls, of which 91 are wholly sustained by the government, while the rest receive aid from it. No insignificant educational influence is exerted by the central museum at Lahore, which is visited by nearly 50,000 persons annually. There are 14 newspapers in the province, all printed in native languages except two, which are in English. In 1872-'3, 344 books were published. About 20,000 men are employed as police, more than half the number being Mohammedans. There are 34 jails; a ticket-of-leave system exists, and the prisoners are employed in industrial pursuits. The number of government hospitals and dispensaries is 116, including the Mayo hospital connected with the medical school at Lahore. A system of elementary medical instruction has been introduced for native physicians, who are supplied with the requisite medicines and paid for their services in times of epidemic.—In a military sense, the position of the Punjaub is more important than that of any other province of India, lying as it does in the very highway of invasion from the interior of the Asiatic continent. A large British force is constantly garrisoned there; in 1872-'3 it consisted of 35,885 men, with 97 field guns. In addition to this, the lieutenant governor had under his orders a frontier force of 12,416 troops, principally Sikhs, Gorkhas, and natives of the Punjaub.—The government of the province is administered by a lieutenant governor, whose official residence is at Lahore. The highest judicial authority is vested in a chief court composed of a barrister and a civilian judge. In addition to Lahore, the chief towns are Delhi, Peshawer, Amritsir, Ambala or Umballa, Rawalpindi, Mooltan, Ferozepore, Leia, and Dera Ismail Khan.—In the year 327 B. C. Alexander the Great invaded the Punjaub, crossed the Indus, Jhylum (anc. *Hydaspes*), Chenaub (*Acesines*), and Ravee (*Hydraotes*), and marched to the right bank of the Beas or of the Sutlej (to either of which the ancient name *Hyphasis* may be referred), which was the limit of his advance eastward. At that time the country

was ruled by a Hindoo monarch named Taxiles in the west, and by a sovereign called Porus, whose dominions extended from the Jhylum to Delhi. After the Greek invasion the whole appears to have become a part of the kingdom of Maghada, which existed until about 195 B. C. For many centuries subsequently the history of the Punjaub is enveloped in much doubt and obscurity. About A. D. 1000 Mooltan appears as a Mohammedan state, though it is not clear how it became so. At this period Mahmoud of Ghuzni invaded India from Afghanistan, subjugated the Punjaub, and made Lahore the seat of his dynasty, which came to an end in 1186. It was afterward subject to numerous different chieftains, principally Afghans, who ruled it until it was invaded and pillaged by Timour and his army in 1398. The Mogul dynasty was finally established over the country by his lineal descendant Baber in 1526. Humayun, son and successor of Baber, lost the province temporarily, but recovered it in 1555 from his Afghan rival, Shere Ali Khan. The Punjaub was the scene of a considerable insurrection in 1709-'11 on the part of the Sikhs, who had long been persecuted by their Mohammedan rulers, and it was quelled with some trouble by Bahadoor Shah, who had not long previously succeeded his father Aurungzebe on the throne. In 1752 the Afghan king Ahmed Shah Abdalli entered the province, exacted contribution from its inhabitants, and a few years later forced the Mogul emperor to cede it to him. Soon afterward the growing power of the Sikhs was manifested by a fresh uprising in the districts E. of the Jhylum. The Afghan dynasty terminated in 1809, and by that time Runjeet Singh, the greatest chieftain of the Sikhs, had acquired Lahore and controlled the larger portion of the province through a confederacy of the various Sikh clans within its boundaries. He endeavored to force the Sikh hill states E. of the Sutlej into this confederacy, and only yielded his claim to their allegiance upon the advance of a British army to the banks of the river. He reigned till 1839, and in the interval conquered Mooltan, Peshawer, and the Derajat district beyond the Indus. A period of anarchy followed the death of his son and successor Khuruk Singh in 1840, and the Sikhs finally determined to invade the British territories in India. Thus, in 1845, began the first Sikh war, in which were fought the battles known as those of the Sutlej. The Sikh forces were defeated with heavy loss, and in 1846 the English took possession of the Jalandhar doab and the Sikh territories on the left bank of the Sutlej, and undertook the guardianship of the young Maharajah Dhuleep Singh, a grandson of Runjeet Singh and then a minor. In 1848 the disaffection of the chieftains led to the second Sikh war, in which the most celebrated battle was fought at Chillianwallah, where the English were nearly defeated; but the result of the contest

was the annexation of the Punjab to the British dominions, by a proclamation of the viceroy on March 29, 1849. (See SIKHS.) During the sepoj mutiny of 1857 Sir John Lawrence (now Lord Lawrence) was chief commissioner of the Punjab, and by his prompt action in disarming the native regiments, the confidence which he displayed in the Sikhs as friends of the British, and his judicious administration generally, the rebellion was rendered utterly unsuccessful in that part of India.

PUNTA ARENAS, the only seaport town of Costa Rica on the Pacific, situated on the E. side of the gulf of Nicoya, about 60 m. W. by N. of San José; permanent pop. about 300. The town stands on a sandy point which projects into the gulf. Vessels drawing more than 7 ft. of water are obliged to anchor 3 m. from shore, in the outer harbor, which is protected from the swell of the Pacific by two islands. An inner harbor, between the point and the mainland, is accessible only for vessels of very light draught. The climate is unhealthy, but less so than that of other parts of the coast. Punta Arenas is the port of San José, with which it is connected by a good carriage road, and a railway is projected. There is a telegraph line to Cartago, which is to be continued to Limon on the Atlantic. The steamers of the Panama railway company and those of the Pacific mail steamship company touch regularly at Punta Arenas. In 1873 the entries at the port were 97 ships, of 15,464 aggregate tonnage. The port was established in 1840, when Caldera, S. of it, was abandoned on account of its unhealthfulness.

PUPA. See BUTTERFLY, and CHRYSALIS.

PURBACH, or **Peurbach**, **Georg**, a German astronomer, born at Peurbach, Austria, in 1423, died in Vienna in 1461. He studied astronomy under Gmunden at the university of Vienna, went to Italy, and on his return succeeded his master in the professorship at Vienna. At the time of his death he was reputed the first astronomer in Europe. He began a new edition of Ptolemy's *Almagest*, based upon the Latin translation from the Arabic; and though he neither understood Greek, in which the work was originally written, nor Arabic, his knowledge of astronomy enabled him to make his edition much better than previous ones. He left this work unfinished to his pupil Regiomontanus, who completed it. The most celebrated of Purbach's own works is his posthumous *Theoria Novæ Planetarum* (1472), which served as an introduction to Ptolemy.

PURCELL, **Henry**, an English composer, born in London in 1658, died Nov. 21, 1695. While a singing boy in the choir of the king's chapel he composed several anthems. At the age of 18 he was appointed organist of Westminster abbey, and six years afterward one of the three organists of the chapel royal. His anthems previously written were very popular, and in 1677 he composed the music for an operetta by Tate, entitled "*Dido and Æneas*," performed

by the pupils of a female boarding school. The success of this work encouraged him to become a regular writer for the stage, and for the play of "*Abelazor*" (1677), Shadwell's adaptation of "*Timon of Athens*" (1678), and Lee's "*Theodosius*" (1680), he composed the overtures and songs. A number of his instrumental pieces in four parts were published by his widow in 1697, under the title of "*A Collection of Ayres*, composed for the Theatre and on other occasions, by the late Mr. Henry Purcell." Next in order of his compositions was a series of 12 sonatas for two violins and a bass published in 1683, followed by another series of 10. Subsequently he produced the greater part of his dramatic music, and set the songs, dialogues, and choruses in several of Dryden's most successful plays. In 1690 he composed new music for the "*Tempest*," as adapted for the stage by Dryden and Davenant, and within the next two years he similarly embellished Dryden's "*King Arthur*," "*Indian Queen*," and "*Tyrannic Love*." For D'Urfey's three parts of "*Don Quixote*," produced in 1694-'6, he furnished the two songs, "*Let the dreadful engines*" and "*From rosy bowers*." He also furnished the music for "*Bonduca*," a tragedy by Beaumont and Fletcher made into an opera by Dryden, in which occurs the well known duet and chorus, "*Britons, strike home*;" and vocal pieces for Beaumont and Fletcher's "*Diocletian*," altered by Betterton, Dryden's "*Aurungzebe*," and Shadwell's "*Libertine*." These works were published by his widow in 1697 under the title of "*Orpheus Britannicus*." His published anthems number 50, besides a celebrated *Te Deum* and *Jubilate*, with orchestral accompaniments; and his church music includes a complete service and a number of hymns and psalms. His odes, glees, catches, rounds, &c., were also numerous and popular. Purcell died of consumption, and was buried in Westminster abbey.

PURCELL, **John Baptist**, an American archbishop, born in Mallow, Ireland, Feb. 26, 1800. He came to the United States at an early age, began his theological studies in Mount St. Mary's college, Emmettsburg, Md., completed them in St. Sulpice, Paris, and was ordained priest in that city in 1826. After his return to the United States he taught theology at Mount St. Mary's, and became president of the college in 1829. He was appointed bishop of Cincinnati in 1833, when there was but one Roman Catholic church there, while the diocese comprised the entire state of Ohio; but the numbers of his flock rapidly increased, and he founded many important institutions. The diocese was divided in 1847 by the erection of Cleveland into an independent see, and the diocese of Columbus was separated in 1868. In 1860 he was made an archbishop. In 1869 he attended the council of the Vatican, and voted against the opportuneness of defining the doctrine of pontifical infallibility. After his return to Cincinnati in 1870, he was involved

in a public discussion with the freethinker Vickers. Previously, in 1837, he had a seven days' discussion with the Rev. Alexander Campbell, which excited great interest, and an account of which was afterward printed in a volume. Archbishop Purcell has published a volume of "Lectures and Pastoral Letters," and edited Kenelm Digby's "Ages of Faith" and Donald Macleod's "History of the Devotion to the Blessed Virgin Mary in North America" (New York, 1866).

PURCHAS, Samuel, an English author, born at Thaxted, Essex, in 1577, died about 1628. He was educated at St. John's college, Cambridge, and in 1604 became vicar of Eastwood in Essex. Removing to London, he received the rectory of St. Martin's, Ludgate, and became chaplain to Archbishop Abbot. He compiled from more than 1,300 authorities a work entitled "Purchas his Pilgrimage, or Relations of the World, and the Religions observed in all Ages, and Places discovered, from the Creation unto this present" (fol., 1613); and a collection of voyages under the title, "Purchas his Pilgrimages" (4 vols. fol., 1625). The third and fourth volumes relate to America. He also wrote "Microcosmus, or the History of Man" (1619), and "The King's Tower, and Triumphant Arch of London" (1623).

PURGATORY (Lat. *purgatorium*, a place for cleansing), in the belief of the Roman Catholic and the eastern churches, a state of temporary suffering in the next world, where the souls of the just expiate the offences committed in this life. The liturgies of the Latin church and of all the eastern churches, without exception, contain prayers for the repose of departed souls. According to Catholic theologians, every sin, no matter how slight, deserves and will receive punishment either before or after death. The absolution of a priest in the sacrament of penance washes away the guilt of sin and remits the eternal punishment due for grave offences, but not the temporal penalty which has to be undergone as a satisfaction to God's justice. Baptism alone removes both the guilt and the penalty; and as few or no adult persons depart this life without having committed sins after baptism, there must be some middle state for such as do not deserve hell and are yet not pure enough to enter heaven. The Catholic church has not defined the nature and duration of the punishment of purgatory, or declared that it is situated in any particular place. She believes that the sufferings of souls in the middle state may be abridged by indulgences, masses, and the prayers of their friends on earth; and one day in the year (All Souls' day, Nov. 2) is specially devoted to services and prayers for their benefit. Roman Catholic theologians commonly teach that the purification of departed souls is effected by fire, while the Greeks regard the soul after death as being purified "through tribulation." This point was left open by the council of Florence in 1439, as was the question concerning the

duration of purgatorial suffering. The Waldenses and other sects in the middle ages protested against the belief in purgatory and the practices it involved. The reformed churches also rejected them.—See Bellarmin, *De Ignis Purgatorio*; Leo Allatius, *De utriusque Ecclesie in Dogmate de Purgatorio perpetua Consensione*; Wiseman, "Lectures on the Doctrines and Practices of the Catholic Church" (2 vols., Baltimore, 1852); and Hodge, "Dogmatic Theology," vol. iii. (New York, 1874).

PURGSTALL, Hammer. See HAMMER-PURGSTALL.

PURITAN, an epithet first applied in 1564 to English nonconformists, which continued to designate them during the reigns of Elizabeth and the first two Stuarts. During the reign of Mary the stricter nonconformist element of the church was driven out of the country, and a number of exiles at Frankfort resolved to use in public worship the Genevan service book, in preference to the book of King Edward VI. They were resisted in this by other exiles and failed, but renewed the struggle on their return to England after the accession of Elizabeth. There were different degrees of puritanism, some seeking a moderate reform of the English liturgy and discipline, others wishing to abolish episcopacy, and some declaring against any church authority whatever. Representatives from these three classes formed the bulk of the settlers of New England, and the union of them in the English civil wars effected the overthrow of royalty and the establishment of the commonwealth. At the time of the restoration the name became one of reproach. Since the relaxation in 1690 of the acts against the nonconformists, it has ceased to designate any particular sect.—See Neal, "The History of the Puritans" (revised ed. by Joshua Toulmin, 5 vols. 8vo, Bath, 1793-7; American ed., with notes by John O. Choules, 2 vols. 8vo, New York, 1844), and Bacon, "The Genesis of the New England Churches" (New York, 1874).

PURPLE (Gr. πορφύρα; Lat. *purpura*), a color produced by the union of red and blue, and of various shades as one or the other of these predominates. The ancients esteemed it more highly than any other color, sometimes making it a distinctive badge of royalty, and again appropriating it to religious uses, as the decorations of the temple and of the garments of the priests. In the Old Testament it is frequently referred to in Exodus and other books. But it is supposed by some that the purple of the Israelites was a scarlet, or even that the term was used generally for any color in which red predominated. Tyrian purple, the purple of the Greeks and Romans, was obtained from the *murex*, a genus of gasteropod mollusks found in the Mediterranean. (See MUREX.) The use of this color passed away with the decline of the Roman empire, and a simple purple color, that is, one not made by using two separate dyes, was not known until a Florentine, Orchillini, discovered the dyeing proper-

ties of the lichen called orchilla weed. Other lichens growing in different parts of the world now furnish the dye known as orchil or archil. (See ARCHIL.) Shades of purple are abundantly obtained from coal-tar colors. (See ANILINE, DYEING, and MAUVE.) The compounds called "purpurates," especially the purpurate of ammonia, called by Liebig and Wöhler murexide, from its resemblance to the Tyrian purple, present beautiful shades of purple. (See PURPURATES.)

PURPLE OF CASSIUS. See CASSIUS, PURPLE OF. **PURPURATES**, salts of purpuric acid. Scheele in 1776 found that a solution of uric in nitric acid produced a beautiful deep red dye. Prout in 1818 obtained this coloring matter in a crystalline form, and regarded it as purpurate of ammonia. By double decomposition he obtained metallic purpurates having a similar color. The colorless substance which separated from purpurate of ammonia by the action of strong acids, he regarded as purpuric acid; but Liebig and Wöhler showed that this did not possess the property of forming colored salts, and therefore held that Prout's compound was not an ammonium salt, but an amide, which they called murexide. (See MUREX.) Later researches by Freitzsch and Beilstein indicate that it is a true ammonium salt; still the purpuric acid has never been isolated, because it is decomposed when its salts are treated with a stronger acid. The formula of purpurate of ammonia or murexide is $C_8H_8N_6O_6 = NH_4C_8H_7N_6O_6$; therefore the acid is represented by the formula $C_8H_7N_6O_6$. Murexide is the principal salt, and is a beautiful purple, but is becoming superseded by rosaniline.

PURSH, Frederick, an American botanist, born in Tobolsk, Siberia, in 1774, died in Montreal, Canada, June 11, 1820. He was educated at Dresden, came to America in 1799, and spent 12 years in botanical explorations. In 1811 he visited England, and published "*Flora America Septentrionalis*, or a Systematic Arrangement and Description of the Plants of North America" (2 vols. 8vo, London, 1814). He was engaged in the collection of materials for a flora of Canada when he died.

PURSLANE, the common name (of obscure derivation) for *portulaca oleracea*, one of the most common weeds of our gardens, and often abbreviated to "pusley." *Portulaca* (the ancient Latin name) gives its name to a small family of succulent annual or perennial herbs, the *portulacaceæ*, closely related to the pink family, from which they are mainly distinguished by their two-sepalled calyx, and the often transversely dehiscent capsule, which opens by the falling away of the upper part as a lid. The common purslane is a prostrate, smooth, annual plant, its fleshy and often reddish stems spreading in all directions, and forming a mat a foot or more across; the alternate or opposite leaves are wedge-shaped or obovate, and half an inch to an inch long; the axillary or terminal flowers sessile; the

two-cleft calyx cohering with the ovary below; petals five, yellow, and with the 7 to 12 stamens inserted on the calyx at the point where it becomes free from the ovary; ovary one-celled, with a deeply five- to six-parted style, ripening to a many-seeded capsule, which opens by a lid; the kidney-shaped seeds are shining and handsomely marked with a network. The flowers open only in bright sunshine, usually about 11 o'clock A. M., and remain but a short time. Purslane has been used as a pot herb from very ancient times, a fact recognized in its specific name, *oleracea*; and though it is but little used in this country, it is cultivated in French gardens as *pourpier*, and seeds of the green, golden, and large golden varieties are offered in their catalogues. When grown rapidly in a rich soil, and properly served, it is to many a most acceptable vegetable. In this country it finds a congenial climate, and is everywhere one of the most

Common Purslane (*Portulaca oleracea*).

prominent weeds; it gives but little trouble before hot weather sets in, but grows then with astonishing rapidity; so tenacious of life is it, that it must be entirely removed from the ground or it will go on and perfect its seeds. Pigs are very fond of it. The hairy purslane, *P. pilosa*, with narrow cylindrical leaves and pink or purple flowers, is found in Florida; and *P. retusa*, which much resembles the common species, with its leaves notched at the ends, is common west of the Mississippi.—The garden portulacas, probably all to be referred to the South American *P. grandiflora*, though several different names have been given to them, have cylindrical leaves and very large showy flowers of the most brilliant colors, from white through yellow, orange, and red, to bright purple, and often striped or blotched with two colors; the double ones are very fine, and deserve the name of "portulaca roses" given them by the German florists.—

The sea purslans, *sesuvium portulacastrum*, found along the shores of the southern states, and *S. pentandrum*, from Long Island southward, have much the habit of the common purslane, but have no petals, though the calyx is purplish inside, and usually numerous stamens.—Black purslane and milk purslane are names given in some parts of the country to *euphorbia maculata* and *E. hypericifolia*, which are also common garden weeds, and have a prostrate habit like purslane; they can at once be distinguished from purslane by their copious milky juice. They belong to a dangerously active family, and the term purslane should not be applied to them, as their proper name is spurge.—Belonging to the purslane family are several interesting genera, including *Claytonia*, with two handsome species known in the eastern states as spring beauty, and a dozen or more on the Pacific coast. *Calandrinia* is an allied showy genus, some species of which are cultivated in gardens.

PURÚS, a river of South America, rising about lat. 14° S., in the mountains E. of Cuzco, Peru, and flowing in a northeasterly direction to its junction with the Amazon, into which it falls by two principal and three minor mouths, the extremes of which are over 100 m. apart. The most easterly branch is 125 m. W. of the Rio Negro. A part of its upper course is on the borders of Peru, Bolivia, and Brazil, and the lower, more than half of the whole, through the latter country. Its entire length is estimated, inclusive of curves, at upward of 2,000 m., and it flows through uninterrupted primeval forests of great beauty. The Purús, probably the Amam-mayu of the Incas and the Madre de Dios of the early Spaniards, is the most important of all the Amazon feeders W. of the Madeira, parallel to which it rolls and with which it communicates. It is navigable uninterruptedly from the Amazon, about lon. 60° 30', to southern Peru.

PUSEY, Edward Bouverie, an English clergyman, born in 1800. He is the second son of the Hon. Philip Bouverie (who assumed the name of Pusey), younger brother of the first earl of Radnor. He graduated at Christ Church, Oxford, in 1822, obtained a fellowship in Oriel college, took orders, and in 1828 became canon of Christ Church cathedral and regius professor of Hebrew in the university, a post which he still holds. He shares with Dr. Newman the reputation of originating the so-called Anglo-Catholic movement in the church of England in 1833, which finds its best exponent in the celebrated "Tracts for the Times." Many of these, including an elaborate treatise on baptism, were written by Dr. Pusey, who also published letters in defence of his views to the archbishop of Canterbury and the bishops of Oxford and London. The characteristic tenets of the "Puseyite" party are judgment by works equally as by faith, baptismal regeneration, the apostolic succession of the clergy, the supreme authority of the church, the expedi-

ency of auricular confession and conventual establishments, and an efficacy in the sacraments of the church not inferior to that claimed exclusively by the Roman Catholic church. They aimed also at certain innovations in the ceremonies of public worship. In 1843 Dr. Pusey preached a sermon before the university, in which he was understood to confess his belief in the doctrine of transubstantiation; and after an examination before a board of judges he was accordingly suspended from the office of preacher within the precincts of the university for three years. He was one of the editors of the "Library of Translations from the Fathers" and of the "Anglo-Catholic Library," and has adapted to the use of the church of England several Roman Catholic devotional works. He has published "Causes of Rationalism in Germany" (1828); "Remarks on Cathedral Institutions" (2d ed., 1833); "Royal Supremacy in Spiritual Matters" (1850); "The Doctrine of the Real Presence, gathered from the Fathers" (1855); "The Real Presence the Doctrine of the English Church" (1857); "History of the Councils of the Church, A. D. 51-381" (1857); "Commentary on the Minor Prophets" (in numbers, 1860-'62); "Daniel the Prophet: nine Lectures" (1864); and "The Church of England a Portion of Christ's one Holy Catholic Church" (1865).

PUSHKIN, Alexander Sergeyevitch, a Russian poet, born in Pskov, June 6, 1799, died in St. Petersburg, Feb. 10, 1837. He was the son of a nobleman, studied at Tzarskoye Selo, and became a clerk in the foreign office. In 1820 he was expelled on account of his "Ode to Liberty," and subsequently he was expelled from Odessa for his tirade against the governor general. The emperor Nicholas, after his accession in 1825, reinstated him in his clerkship at St. Petersburg, and appointed him to prepare the history of Peter the Great. This shook his friends' belief in his liberalism, and his life was further embittered by what he fancied to be undue attentions paid to his beautiful wife by George Charles d'Anthès, a French officer in the Russian army (the future senator baron de Heeckeren). Although d'Anthès married Mme. Pushkin's sister to disarm the husband's suspicion, Pushkin fought a duel with him and was killed. The emperor gave a pension of 10,000 rubles to the widow, and provided for the children's education, and for the publication of a superb edition of Pushkin's works. A public subscription for a monument in his honor amounted on Jan. 1, 1874, to about 75,000 rubles. Among his earliest works were the poems "Ruslan and Liudmila," "The Prisoner of the Caucasus," a sketch, and "The Fountain of Bakhchiseraï," resembling Byron's "Corsair." His masterpiece, "Eugene Onegin," a novel in verse, appeared between 1825 and 1828. His other works include the narrative poems "The Gypsies" (1827) and "Poltava" (1829); the dramatic poems "Boris

Godunoff" and "The Stone Guest" (1836); and the novels "The Captive's Daughter" and "The Captain's Daughter." The latter and other novels are comprised in "Russian Romance, from the Tales of Belkin," an English translation by Mrs. J. Buchan Telfer, *née* Muravieff (London, 1875). Prosper Mérimée and Viardot have translated some of his works into French, and Bodenstedt and others into German. The best complete editions of Pushkin's works are by Anenkoff (7 vols., St. Petersburg, 1854-'7) and Gennadi (6 vols., 1869 *et seq.*).

PUSTULE, Malignant, a specific disease, essentially septic and gangrenous, confined to the cutaneous tissue, and generally to those parts of the surface that are habitually uncovered. It appears most commonly on the face, and next on the hands, neck, and arms. It first appears in the form of a painful swelling, which, after a lapse of time varying from one to three days, rarely more, develops upon its central part a small reddish or purple spot, accompanied with itching. In the course of 12 or 15 hours more this spot changes into a bleb or vesicle, not usually larger than the head of a pin, containing a reddish brown or yellowish fluid. Owing to continued itching, the vesicle is ordinarily ruptured soon after its appearance; if otherwise, it dries up in about 36 hours, leaving the exposed derma dry, and generally of a livid color. Itching now ceases; and, after a time varying from a few hours to a day, the centre of this discolored and denuded surface begins to grow hard and becomes surrounded by an inflamed areola covered with numerous small vesicles similar to the vesicle which first appeared. The middle of this areola is depressed, and the color varies from yellow to black. It is now hard in the centre and more painful than at any other stage. But it is a remarkable feature of malignant pustule that severe pain is generally absent; and this character, so different from all other acute inflammations of the skin, is a valuable negative diagnostic of the disease. During the next 24 or 48 hours the subcutaneous tissue becomes involved; the tumor strikes deeper and rapidly extends in all directions, yet it is so indurated as to be easily circumscribed, and its confines determined without difficulty. Meanwhile the central point, now of brown or livid hue, exceedingly hard and insensible, becomes gangrenous. If the disease makes no further progress, an inflamed circle of vivid redness now surrounds the gangrenous portion; the tumefaction, which had before rapidly extended, diminishes; and the patient experiences something like an agreeable warmth accompanied by a pulsatory motion of the affected part. The pulse, which had before grown irritable and feeble, revives; strength increases; if there has been some degree of fever, as occasionally happens, it is now resolved into a gentle perspiration; suppuration sets in between the living and the

dead parts, and the detachment of the gangrenous portion leaves a suppurating surface of variable extent in different cases. When the disease tends to an unfavorable issue, generally no suppuration takes place; the gangrene spreads rapidly from the centre to the circumference of the tumor; the pulse becomes smaller and more contracted; the patient complains of extreme lassitude with inability to sleep, is attacked with fainting fits, and becomes passive as to the result; there is disinclination to take food or medicine, or have anything done, and a total loss of appetite; the tongue is dry and brown; the features shrink; the skin is parched; the eyes are glassy; and increasing debility and a low delirium indicate a fatal termination. Such are in general the ordinary phenomena of malignant pustule, usually terminating in from five to eight days. Exceptional fatal cases have been recorded, varying from 24 hours to 16 days. In the suddenly fatal cases, the forces of the constitution are so quickly and entirely subverted by the malignancy of the disease, that few symptoms are manifested; the powers sink under it, as it were, without resistance. It is most fatal when attacking the face or neck.—Another variety, which commonly attacks the hands or arms, is of a less regular character, in some cases presenting an appearance and running a course very similar to a circumscribed phlegmon, while in others it is exceedingly violent and fatal in a few hours, and in others still runs on for several weeks, and finally proves fatal rather from the effects of the disorder than from the disease itself. In the majority of these cases there is intense local pain in the affected part from the commencement, with enormous swelling and more or less redness. A small vesicle or pustule forms in the centre, and takes on a gangrenous character. Sometimes it becomes circumscribed and limits its action to the skin; but at other times numerous phlyctenæ cover the surface, and the destructive inflammation burrows into the cellular tissue which envelops the muscles, completely surrounding and disintegrating these organs, which become soft, black, and gangrenous. The blood vessels and nerves also become involved, and as a necessary consequence the death of the part ensues.—The pathology of malignant pustule is distinguished by a fluid state of the blood, which is usually very dark-colored; the texture of the heart is softened, and its surface covered with ecchymosed spots; the veins are sometimes softened and ecchymosed, and usually contain black or yellowish white clots of blood, of gelatinous consistence. The lungs are covered with superficial ecchymoses, presenting over their surface a number of deeply penetrating black spots, produced by local sanguineous infiltration. The inner coat of the stomach and intestines presents in different places, corresponding to the course of the vessels, prominent, dark-colored spots, formed by blood effused between the inner coats and the peritoneal cov-

ering.—*Causes.* It is the general conclusion of those who have investigated the nature of malignant pustule, that the germ of the disease consists in an animal poison, usually contracted by man from cattle or their remains. In support of this view, it is found that the disease most frequently occurs among knackers, tanners, veterinarians, persons engaged in the removal of offal, and stevedores, particularly those employed in handling hides from districts and countries where the diseases of cattle most prevail. In other cases it has been attributed to eating diseased animal food. Yet, strange as it may appear, in the whole scope of veterinary medicine no disease is known which accurately resembles the malignant pustule of man. Certain herbivorous animals, especially beasts of pasture, are subject to a disease called malignant carbuncle, characterized by the occurrence of a large uncircumscribed emphysematous tumor, which yields to pressure and crepitates under the fingers, and exhales a peculiar putrid odor. In its progress it turns black in the centre, and appears as if burned or charred; it is infiltrated with a yellowish colored fluid, and distended with a fetid gas. This disease may be transmitted from one animal to another by inoculation, and by absorption to man, in whom it runs a violent and dangerous course. MM. Salmon and Manoury of France have vainly attempted to limit the term malignant pustule to this disease only. Malignant carbuncle and other ulcers which occur in cattle are the eruptive symptoms of grave febrile disorders depending upon a diseased state of the blood, and always consecutive to the febrile symptoms; and the inoculation of man with matter from such an ulcer is only equally dangerous with the blood, and possibly the milk, of the same animal in the febrile state before the ulcer appeared. Indeed, cases have occurred where the blood of animals not previously known to have been diseased has caused malignant pustules in man by absorption. It is the opinion of some observers that malignant pustule may occur spontaneously, without any contact with poisonous animal matter. But from the fact that diseased animal matter is known to cause the great majority of cases, many ways will readily suggest themselves by which inoculation might take place without any knowledge of the circumstance on the part of the person affected. As a general rule, cattle which feed on prairie meadows are exempt from malignant disease; while those which are fed upon dried clover, lucern, and vetch are peculiarly liable to carbuncle. The same may be said of cattle that are fed upon semi-decomposed grain, the refuse of distilleries and breweries. All such things are actively predisposing agents to the blood diseases of cattle, and liable to engender malignant pustule in man.—*Treatment.* Promote suppuration in the pustule as rapidly as possible, and sustain the constitution. To this end, as soon as the nature of the disease is as-

certain, the vesication formed on its surface should be opened, the fluid contents removed, and the denuded part covered with a drossil of lint dipped in a strong solution of muriate of ammonia or other caustic. Six hours afterward this may be removed and a poultice applied; and 24 hours after this, if pain and burning heat have nearly or quite ceased, and no areola has formed, it may be safely concluded that the caustic has effectually permeated the whole of the diseased tissue, and that it will proceed to a healthy suppuration by the continued application of poultice. But if, on the contrary, a hard and deep-seated painful tumor has formed around the primary seat of the vesicle, we may take it for granted that the disease is extending itself. The tumor should be forthwith divided through the whole width and depth by a crucial incision, the gangrenous parts removed if any have formed, and the nitrate of silver or fused potassa thoroughly applied to the freshly divided surfaces. This proceeding is equally requisite when the slough which forms on the centre quickly becomes hard and impermeable, like a piece of dry hide; this must be removed to admit of the unimpeded action of the caustic. Scarifications and cauterizations, with the continued application of poultice, should be repeated daily until suppuration is established, or until the extent of the pustule is clearly defined. Internally, the bowels being first cleared by a mild cathartic, quinia (four or five grains every three or four hours), with wine or brandy, and as much food as the patient can be induced to take (there being generally disinclination to take food), and opiates with camphor, as much as may be necessary to allay pain and produce sleep, constitute the basis of treatment. In spite of everything, the peculiar contagion of malignant pustule, being in the blood, frequently proceeds straight on to a fatal termination; and this is sometimes the case even when the pustule seems to have been checked. On recovery from malignant pustule, the deformities consequent upon its ravages sometimes require surgical operations for their relief.—*History.* Malignant pustule was known to the ancients. Celsus and Paulus Aegineta both described it under the head of carbuncle. Ambroise Paré, in the 16th century, distinguished it from plague. Yet it was not until the latter part of the 18th century that physicians began to appreciate its nature. Thomassin, Boyer, Fournier, Montfils, Veson, Sancerotte, Chambon, and especially Enaux and Chaussier, contributed to make the medical world acquainted with the nature of malignant pustule. During the present century, Bayle, Bidault, Villiers, Reynier, Rayer, Branell, Wagner, Raimbert, Manoury, and Salmon, and more recently Bourgeois and Gaujot, have given valuable monographs of cases and epidemics. In the United States, it has at least twice prevailed epidemically: in the vicinity of Philadelphia in 1834-'6, and in Louisiana in 1837-'9. It is also

said to have prevailed in Louisiana soon after its settlement by the French. It is not known to have occurred in the northern portion of the United States otherwise than sporadically; unless, possibly, the "malignant erysipelas" which prevailed in the northern part of the state of New York in 1825 was a variety of malignant pustule; it was immediately preceded by a fatal epizootic of slavers among horses. In the same region, and just subsequent to an epizootic among horned cattle in 1842, there were several cases of genuine malignant pustule, yet no one seems to have recognized its source. Since that time, and it may be added since the common practice of feeding cattle on the refuse of distilleries and breweries, and the more general spread of epizootic diseases, particularly in the northern part of the United States, malignant pustule has become more common. Both of the epidemics referred to were in conjunction with epizootics.

PUTLITZ, *Gustav Heinrich Gans zu*, a German poet, born at Retzien, Prussia, March 20, 1821. He studied in Magdeburg, Berlin, and Heidelberg, and was employed in the civil service from 1846 to 1848. In 1863 he became director of the court theatre at Schwerin. His exquisite fairy poem, *Was sich der Wald erzählt* (Berlin, 1850; 32d ed., 1872), served as a model for many similar works, and was followed by *Vergissmeinnicht* (1851; 9th ed., 1872), *Die Halben* (1869), *Walpurgis* (1870), and *Funken unter der Asche* (1871). He has also written *Brandenburger Geschichten* (Stuttgart, 1862), *Novellen* (1863), and numerous dramas and comedies, the latter collected in many volumes, 1850-'69. His collected works appeared in 1872.

PUTNAM, the name of counties in nine of the United States. **I.** A S. E. county of New York, bordered W. by the Hudson river, E. by Connecticut, and watered by Croton river and Peekskill creek; area, 234 sq. m.; pop. in 1870, 15,420. Its surface is mountainous, several ranges crossing the county from S. W. to N. E., and the deep valleys are fertile. There are several beautiful mountain lakes, the principal of which are Mahopae, Canopus, and Gleneida. Iron, granite, limestone, and other minerals are found in the mountains, and there are many mines and quarries. It is traversed by the Hudson River and the New York and Harlem railroads. The chief productions in 1870 were 2,599 bushels of wheat, 89,934 of Indian corn, 49,673 of oats, 101,595 of potatoes, 33,671 tons of hay, 3,707 lbs. of wool, and 277,759 of butter. There were 2,184 horses, 10,220 milch cows, 1,480 working oxen, 2,141 other cattle, 2,119 sheep, and 2,015 swine; 3 flour mills, 3 paper mills, 2 founderies, and 5 manufactories of tin, copper, and sheet-iron ware. Capital, Carmel. **II.** A W. county of West Virginia, touching the Ohio with its W. corner, intersected by the Great Kanawha, and drained by its tributaries; area, about 350 sq. m.; pop. in 1870, 7,794, of whom 260 were colored. It has a

rough and hilly surface and a generally fertile soil, and contains extensive beds of iron ore and bituminous coal. The Chesapeake and Ohio railroad crosses the S. corner. The chief productions in 1870 were 40,020 bushels of wheat, 232,126 of Indian corn, 49,879 of oats, 28,090 of potatoes, 472,765 lbs. of tobacco, 14,992 of wool, 63,061 of butter, and 19,541 gallons of sorghum molasses. There were 1,463 horses, 1,565 milch cows, 3,035 other cattle, 6,291 sheep, and 6,999 swine. Capital, Winfield. **III.** A central county of Georgia, bordered E. by the Oconee and drained by Little river and several creeks; area, about 350 sq. m.; pop. in 1870, 10,461, of whom 7,445 were colored. It has a nearly level surface, abounding with forests of oak and pine, and a soil naturally fertile. The Milledgeville branch of the Central railway of Georgia terminates at Eatonton. The chief productions in 1870 were 11,040 bushels of wheat, 160,661 of Indian corn, 7,872 of oats, 14,848 of sweet potatoes, 7,326 bales of cotton, 3,328 lbs. of wool, and 29,047 of butter. There were 464 horses, 1,100 mules and asses, 1,541 milch cows, 465 working oxen, 2,250 other cattle, 1,538 sheep, and 4,346 swine. Capital, Eatonton. **IV.** An E. county of Florida, bounded E. by St. John's river and drained by its tributaries; area, 610 sq. m.; pop. in 1870, 3,821, of whom 1,334 were colored. The surface is low and level, and the soil fertile. It contains several small lakes. The chief productions in 1870 were 16,592 bushels of Indian corn, 11,673 of sweet potatoes, 162 bales of cotton, 1,125 lbs. of rice, and 4,823 gallons of molasses. There were 1,055 milch cows, 5,526 other cattle, 360 sheep, and 2,710 swine. Capital, Palatka. **V.** A N. county of Tennessee, drained by affluents of the Cumberland river; area, about 500 sq. m.; pop. in 1870, 8,698, of whom 530 were colored. It has a hilly surface, and much of it is covered by forests. The chief productions in 1870 were 39,330 bushels of wheat, 332,254 of Indian corn, 37,854 of oats, 17,367 of Irish and 11,581 of sweet potatoes, 131,856 lbs. of tobacco, 19,092 of wool, 125,938 of butter, 18,945 of honey, and 17,772 gallons of sorghum molasses. There were 2,218 horses, 2,166 milch cows, 1,364 working oxen, 2,865 other cattle, 10,460 sheep, and 21,568 swine. Capital, Cookville. **VI.** A N. W. county of Ohio, drained by Auglaize river and its tributaries, the Ottawa and Blanchard's fork; area, about 500 sq. m.; pop. in 1870, 17,081. It has a level surface, is covered with large tracts of timber, and its soil is fertile. It is intersected by the Cincinnati, Hamilton, and Dayton railroad. The chief productions in 1870 were 237,586 bushels of wheat, 434,948 of Indian corn, 105,896 of oats, 70,527 of potatoes, 16,331 tons of hay, 78,605 lbs. of wool, 330,078 of butter, 14,098 of maple sugar, and 12,801 gallons of sorghum molasses. There were 5,437 horses, 5,242 milch cows, 7,191 other cattle, 23,269 sheep,

and 15,466 swine; 8 manufactories of carriages and wagons, 1 woollen mill, 6 flour mills, and 14 saw mills. Capital, Ottawa.

VII. A W. county of Indiana, drained by a branch of Eel river and several creeks; area, 486 sq. m.; pop. in 1870, 21,514. It has an undulating surface and fertile soil. It is intersected by the Indianapolis and Illinois canal and several railroads. The chief productions in 1870 were 297,797 bushels of wheat, 988,919 of Indian corn, 68,565 of oats, 57,710 of potatoes, 15,990 tons of hay, 125,320 lbs. of wool, 332,383 of butter, 33,289 of maple sugar, and 21,207 gallons of sorghum molasses. There were 8,274 horses, 2,416 mules and asses, 5,729 milch cows, 19,236 other cattle, 34,227 sheep, and 26,777 swine; 16 manufactories of carriages and wagons, 3 of furniture, 2 of curried leather, 3 of pumps, 6 of tin, copper, and sheet-iron ware, 3 founderies, 1 woollen mill, 4 flour mills, and 16 saw mills. Capital, Greencastle.

VIII. A N. central county of Illinois, intersected by the Illinois river and drained by its branches; area, 200 sq. m.; pop. in 1870, 6,280. It has an undulating surface and fertile soil. It is traversed by the Chicago, Rock Island, and Pacific railroad. The chief productions in 1870 were 28,933 bushels of wheat, 334,259 of Indian corn, 86,519 of oats, 73,707 of potatoes, 10,571 lbs. of wool, 47,699 of butter, 4,916 gallons of sorghum molasses, and 5,080 tons of hay. There were 2,420 horses, 1,406 milch cows, 2,899 other cattle, 1,987 sheep, and 5,431 swine. Capital, Hennepin.

IX. A N. county of Missouri, bordering on Iowa, bounded E. by the Chariton river and drained by its branches; area, about 550 sq. m.; pop. in 1870, 11,217, of whom 9 were colored. It has an undulating surface, diversified by prairies and forests, and a fertile soil. The chief productions in 1870 were 62,308 bushels of wheat, 458,582 of Indian corn, 146,152 of oats, 34,979 of potatoes, 12,911 tons of hay, 39,200 lbs. of tobacco, 63,800 of wool, 194,098 of butter, 10,885 of cheese, 26,365 of honey, and 32,483 gallons of sorghum and 14,731 of maple molasses. There were 5,329 horses, 515 mules and asses, 4,137 milch cows, 9,351 other cattle, 26,227 sheep, and 21,789 swine. Capital, Unionville.

PUTNAM, Israel, an American soldier, born in the part of Salem now constituting the town of Danvers, Mass., Jan. 7, 1718, died in Brooklyn, Conn., May 19, 1790. He was the 11th in a family of 12 children, and in his boyhood was noted for his physical strength and bravery; but he had few educational advantages. On coming of age he bought a farm in Pomfret, Conn., and fixed his residence there. Here occurred his famous encounter with a she wolf that had for several years preyed upon the flocks and cattle of the neighborhood. Having discovered her den, Putnam entered it alone by creeping into a narrow opening, and shot and killed the wolf as she was advancing to attack him. This adventure, which gave

him a wide reputation for courage, took place when he was 25 years old. The next 12 years he spent as a careful and successful farmer. In 1755 he was appointed by the legislature a captain in Col. Lyman's regiment, and formed a strong company from among his neighbors, who were employed chiefly on special service as rangers. His first expedition was under Sir William Johnson against Crown Point. In 1756 he was reappointed under his old commander Lyman, and in 1757 the legislature of Connecticut gave him the commission of major. Perhaps the most important service rendered by him during that year was the saving of the powder magazine of Fort Edward at the conflagration of the barracks. For an hour and a half he contended with the fire, and he was severely burned in his efforts to arrest its progress. In 1758, to escape from a strong party of Indians, he descended with a few men the falls of the Hudson at Fort Miller in a bateau. The savages with admiration beheld him unharmed by their balls steering his boat down rapids never before passed. The same year, when returning to Fort Edward from an expedition to watch the enemy in the neighborhood of Ticonderoga, his corps was surprised by a party of French and Indians, and he himself captured and bound to a tree. While in this situation a battle between his own party and the enemy raged around him for an hour, the tree being for part of the time in the hottest fire. At length the French and Indians were forced to retreat, but carried with them their captive, whom the savages determined to roast alive. He was tied to a tree, and the fire was already blazing, when his life was saved by the French commander, Molang. The next day he was taken to Ticonderoga, and afterward to Montreal, where among other prisoners he met Col. Peter Schuyler, through whose intervention he was treated according to his military rank and exchanged. In 1759, having meanwhile been made lieutenant colonel, he served under Gen. Amherst. In 1762 he commanded a Connecticut regiment in the expedition against Havana. In 1764 Putnam, now a colonel, at the head of 400 Connecticut men accompanied Col. Bradstreet to Detroit in the Pontiac war. For some years afterward he kept an inn at Brooklyn, the capital of Windham county, and during the same period frequently represented the town in the legislature. In 1773 he was engaged in the expedition that went up the Mississippi to survey a tract above Natchez for settlement. In the revolutionary war Putnam from the beginning embraced zealously the cause of the colonists. In April, 1775, at the alarm occasioned by the battle of Lexington, he left his plough in the field, turned loose the oxen, and rode to Boston in one day, a distance of 68 m. Learning that the British were besieged in Boston, he went to Hartford to meet with the legislature, of which he was a member. Being elected by that body brigadier general, he promptly gath-

ered and organized a regiment, and after drilling them for some days marched to Cambridge. The British officers offered him a commission as major general in the royal service and a large sum of money, both of which he indignantly rejected. In May he led a battalion of 300 men to Noddle's island, now East Boston, and burned a British schooner, captured a sloop, killing and wounding 70 of the enemy, and brought off several hundred sheep and cattle. It was in great measure through his wish to bring on a general engagement while the spirit of the troops was high, that the determination was taken to fortify Bunker hill. In the battle which followed he acted a conspicuous part. When Washington arrived at the camp to take command in July, he brought with him commissions from congress for four major generals, one of whom was Putnam; and to him alone did he deliver his commission, the others being withheld on account of the general dissatisfaction attending these appointments. In March, 1776, Washington being about to take possession of Dorchester heights, Putnam was ordered to attack Boston with 4,000 men in case the enemy should attempt to dislodge the Americans. Soon after the evacuation of that city he was ordered to take command in New York. He participated in the battle of Long Island, Aug. 27, and afterward went to Philadelphia to prepare for the defence of that place. After completing the necessary fortifications, he was stationed at Crosswick and subsequently at Princeton. In May, 1777, he was ordered to take command in the highlands of New York. While there he sent the following famous reply to Sir Henry Clinton, who claimed a lieutenant of a tory regiment as an officer in the British service: "Edmund Palmer, an officer in the enemy's service, was taken as a spy lurking within our lines; he has been tried as a spy, condemned as a spy, and shall be executed as a spy, and the flag is ordered to depart immediately. Israel Putnam. P. S. He has been accordingly executed." In the summer of this year the British troops surprised and took Forts Montgomery and Clinton, and obliged Putnam to retire to Fishkill. Subsequently he was removed from his command in the highlands, as Washington says, "on account of the prejudices of the people," and the dissatisfaction of Hamilton and other officers, and also from the fact that a court of inquiry had been ordered to investigate the causes of the loss of Forts Montgomery and Clinton. This court decided unanimously that no blame could be attributed to Putnam, who not long afterward was stationed in Connecticut. In March, 1779, a corps of 1,500 British troops under command of Tryon made an incursion into that state and approached Horseneck, one of Putnam's outposts. To oppose him were 150 men with two pieces of artillery, and with these Putnam took his position on the brow of a steep hill. After exchanging shots, as he saw

the enemy's dragoons were about to charge, he ordered his men to retire to a swamp inaccessible to cavalry. He himself was hotly pursued, and finding that the dragoons were gaining upon him, he rode down a steep declivity, receiving on his passage a ball through his hat. Riding on to Stamford, he called out the militia, and effecting a junction with his little party he hung upon the rear of Tryon in his retreat and took about 50 prisoners, whom he treated with a humanity customary on his part, but so unexpected that the British general sent him a letter of thanks. During the summer of 1779 Putnam held command of the Maryland, Pennsylvania, and Virginia troops in the highlands of New York, and, assisted by his cousin Rufus Putnam and others, completed the fortifications at West Point. After the army went into winter quarters, he returned home, and on setting out again for camp was attacked by paralysis of his left side. He then took up his residence on his farm in Brooklyn, and there remained until his death. He was of medium height and of great physical strength; and decision and personal daring were his most marked characteristics. "He dared to lead where any dared to follow," is the inscription upon his tombstone. His life is contained in the "Miscellaneous Works" of Gen. David Humphreys (New York, 1790), and in Sparks's "American Biography," vol. vii., by O. W. B. Peabody.

PUTNAM, Mary Lowell, an American authoress, daughter of the Rev. Dr. Charles Lowell, born in Boston, Dec. 3, 1810. She was married April 5, 1832, to Samuel R. Putnam, a merchant of Boston, who died in 1861. She possesses a remarkable knowledge of languages, comprising not only Latin, Greek, and Hebrew, and the modern tongues of western Europe, but Swedish, Danish, Polish, Russian, Hungarian, Turkish, Sanskrit, and other oriental tongues. She has published "Record of an Obscure Man" (Boston, 1861); a dramatic poem in two parts, "Tragedy of Errors" and "Tragedy of Success" (1862); and a memoir of her son William Lowell Putnam, killed at the battle of Ball's Bluff in 1861.

PUTNAM, Rufus, an American pioneer, cousin of Gen. Israel Putnam, born in Sutton, Mass., April 9, 1738, died in Marietta, O., May 1, 1824. In 1757 he enlisted in the war against the French, and in 1760 was made ensign. He afterward worked as a farmer and millwright, and in 1773 went on an expedition to the newly created government of West Florida. In 1775 he entered the continental army as lieutenant colonel, in 1776 was appointed engineer with the rank of colonel, and in 1777 commanded a regiment in the Massachusetts line. He constructed the fortifications at West Point, and in January, 1783, was commissioned brigadier general. He removed to Rutland in 1782, and for several years was a member of the legislature and employed in government surveys. After a visit to the Ohio country he called and

presided over a convention that met in Boston on March 1, 1786, and formed the Ohio company, of which he was made a director. The company bought 1,500,000 acres of government land, and Putnam landed at the mouth of the Muskingum on April 7, 1788, and laid out the city of Marietta, the first permanent settlement in Ohio. In 1790 he was appointed judge over the territory N. W. of the Ohio, and in 1796 surveyor general of United States lands. In May, 1792, he had been appointed a brigadier general in the United States army, and commissioned to make a treaty with the tribes on the Wabash. In 1803 Jefferson removed him from the surveyorship, and in the same year he was a member of the convention which framed the Ohio state constitution.

PUTREFACTION. See FERMENTATION, vol. vii., p. 144.

PUTTY, a kind of cement used for filling cavities in cabinet and carpenter's work, for fastening window panes in sashes, and kindred purposes. Ordinary glazier's putty is made of whiting (finely levigated chalk) and boiled linseed oil, kneaded into a doughy mass and beaten with a mallet. The addition of a small quantity of tallow prevents its getting too hard. French putty is made by boiling 4 lbs. of brown umber in 7 lbs. of linseed oil for about two hours, adding 2 oz. of melted wax, 5½ lbs. of whiting, and 11 lbs. of dry white lead, mixing well. This putty is very durable.

PUVIS DE CHEVANNES. See supplement.

PUY, Le, a town of France, capital of the department of Haute-Loire, 270 m. S. S. E. of Paris; pop. in 1872, 19,532. It is at the junction of the valleys of the Loire, Borne, and Dolaison, and is one of the most picturesque towns of France. It is on the steep southern acclivity of Mont Anis, which is crowned by a mass of volcanic rock with a flat top, called *Rocher de Corneille*. On this was erected in 1860 a colossal statue of the Virgin, made from 213 iron cannon captured at Sebastopol. The principal part of the town occupies a series of terraces. The cathedral, a fine Romanesque building of the 10th century, is reached by a stairway of 118 steps. Le Puy has also two ecclesiastical seminaries, a lyceum, normal school, public library, museum, theatre, and institutions for the deaf and dumb and the blind. It manufactures lace, bells, and clocks.

PUY-DE-DÔME, a S. central department of France, in Auvergne, bordering on Allier, Loire, Haute-Loire, Cantal, Corrèze, and Creuse; area, 3,073 sq. m.; pop. in 1872, 566,463. It is traversed by the Forez mountain, branches of the Cévennes, and the Auvergne group, among the highest summits of which are the Puy de Dôme, nearly 5,000 ft., and Mont Dor or Dore, more than 6,000 ft. There are many extinct volcanoes. The chief river is the Allier. A large part of the surface consists of the fertile valley of Limagne. Mineral springs, lead, antimony, coal, and timber abound. The soil, though stony, is pro-

ductive, particularly in the north; there are large orchards, vineyards, and chestnut plantations. It is divided into the *arrondissements* of Ambert, Clermont-Ferrand, Issoire, Riom, and Thiers. Capital, Clermont-Ferrand.

PUZZLES. See supplement.

PYAT, Félix, a French author, born in Vierzon, department of Cher, Oct. 4, 1810. He studied law in Paris, and was admitted to the bar in 1831, but devoted himself entirely to literature and politics. He contributed to several journals, furnished Jules Janin with one of the most striking chapters of his *Barnave*, and was connected as *feuilletoniste* with the *Siècle*, and afterward for several years as political editor with the *National*. His first play, composed in conjunction with Théodore Burette, *Une révolution d'autrefois*, was brought out at the Odéon, March 1, 1832, but was suppressed at once on account of its bold political allusions. *Une conjuration d'autrefois*, printed in 1833 in the *Revue des Deux Mondes*, and *Arabella*, in which, under assumed names, he branded the supposed accomplices in the death of the duke of Bourbon, were of a similar political character. In conjunction with Luchet, he produced in 1834 *Le brigand et le philosophe*, and in 1835 *Ango*. Politics now engaged his attention for about six years. In 1841 his *Deux serruriers* had an extraordinary run; and his *Cedric le Norvégien* (1842), *Diogène* (1846), and *Le chiffonnier* (1847), his last play, were also successful. In 1844, for a violent pamphlet, *Marie Joseph Chénier et le prince des critiques*, against his former friend Jules Janin, he was sentenced to six months' imprisonment. He left the *National* for the more revolutionary *Réforme*, and on the proclamation of the republic in 1848 sided with the socialists. Elected to the constituent assembly, he became one of its secretaries, and voted with the party of the mountain. After his reelection in 1849, he signed Ledru-Rollin's "Appeal to Arms," June 13, accompanied him to the *conservatoire des arts et métiers*, and making his escape first took refuge in Switzerland, and then removed to Belgium, where he occasionally wrote political pamphlets, became connected with the "European revolutionary committee," and wrote an apology for the attempt to assassinate Napoleon III. He refused to profit by the amnesty granted by the emperor in 1859; but after that of 1869 he returned to France. In the same year, however, he was again forced to conceal himself on account of prosecutions brought against him for articles in the *Rappel*. At first he remained in hiding in Paris, but after the plebiscitum of May, 1870, more vigorous measures were taken against him, and he escaped to London. He was found guilty of taking part in various revolutionary conspiracies, and although safe from arrest was sentenced *in contumaciam* to five years' imprisonment and a heavy fine. On the fall of the empire Pyat returned to Paris, and during the German siege edited the *Combat* and the *Ven-*

geur. After the surrender he was elected to the national assembly from one of the city districts; but he appeared only once at the debates. On the outbreak of the insurrection of the commune (March 18, 1871), he was chosen a member of the communal body by the tenth Paris arrondissement. Here his course, throughout the insurrection, was very arbitrary. Most of the acts of violence were supported by him, and he was chiefly instrumental in the suppression of many of the Paris journals for articles which he deemed hostile to the commune's rule. He was successively a member of the first executive committee of the commune, of several special commissions, and of the committee of public safety, under whose rule the last acts of the communists were perpetrated. On the capture of Paris by the Versailles troops he made his escape, and has since lived chiefly in London. Here, in June, 1874, after the artist Courbet had been condemned to pay the cost of reërecting the column Vendôme, Pyat published a protest, assuming himself all responsibility for the decree under which the column was destroyed.

PYDNA (now *Kitro*), an ancient town of southern Macedonia, near the W. shore of the Thermaic gulf. It was a Greek colony, but was repeatedly subjected by the Macedonian kings, and finally by Philip, who enlarged and fortified it. Here Æmilius Paulus vanquished Perseus, the last king of Macedon (168 B. C.). Under the Romans it was also called Citrum or Citrus, from which its modern name is derived.

PYGMALION, a legendary king of Cyprus, whom the licentious conduct of his countrywomen so disgusted that he conceived a hatred against the whole sex. According to Ovid, he made an ivory female statue of such exceeding beauty that he fell desperately in love with it himself, and prayed to Venus to endow it with life. The goddess granted his request. Pygmalion then married the object of his affections, and by her had a son called Paphus, who founded the city of that name. (For another legendary Pygmalion, see *Dmo.*)

PYGMY, or *Pigmy* (Gr. *πυγμαῖος*, from *πυγμή*, the fist, or a measure extending from the elbow to the fist, equal to about 18½ inches), the name of a nation of dwarfs believed by the ancients to inhabit the interior of Africa. They were supposed to be about three spans high, and according to the favorite story they were engaged in constant war with the cranes, their inveterate enemies. Herodotus speaks seriously of them (ii. 32) as an existing race; and many recent commentators have believed that the accounts from which he took his information had confounded a small species of African apes with men. The story of a pygmy race was universally regarded as entirely fabulous until a very recent period. Dr. Krapf, a German missionary, was (about 1850) the first to revive the old myth, in accounts of a tribe of dwarfish negroes of which he had heard in the unexplored part of S. E. Africa. Du Chailu's

explorations enabled him to give still more definite statements, which were long doubted, but the mystery surrounding the subject was finally cleared away by the discoveries of Dr. Georg Schweinfurth. In the country of the Monbuttoos, between lat. 3° and 4° N. and lon. 28° and 29° E., during a long time passed at the king's residence (1870) he was brought into actual communication with a considerable number of people from a pygmy race, inhabiting a district nearly corresponding to that indicated by the ancient story. The first of the pygmies whom he examined was brought by the Monbuttoos to his tent. Dr. Schweinfurth says: "With his own lips I heard him assert that the name of his nation was Akka; and I further learnt that they inhabit large districts to the south of the Monbuttoo, between lat. 2° and 1° N. A portion of them are subject to the Monbuttoo king, who, desirous of enhancing the splendor of his court by the addition of any available natural curiosities, had compelled several families of the Akka to settle in the vicinity." Schweinfurth soon after saw many other representatives of this strange colony, and even succeeded in carrying away one of them; but he died before the explorer reached the coast. No one of six specimens that he measured, some of whom were of advanced age, much exceeded 4 ft. 10 in. in height. Their heads were disproportionately large, their shoulders peculiar in shape, with crooked and singularly formed blades; the chest was flat and contracted above, but expanded below to support the belly, which Schweinfurth says is "huge and hanging." All the lower joints are angular and projecting except the knees, which are plump and round. The feet turn inward, and the Akka "waddle and lurch" in walking. The hands alone are remarkably well formed. The skulls of all examined were prognathous to an extraordinary degree, the facial angles of two of them being respectively 60° and 66°. They have a snout-like projection of the jaws, with an unprotruding chin; the upper part of the skull is wide and almost spherical. At the base of the nose there is an unusually deep indentation. Of their country he could only learn that it was scantily watered and probably flat; that it was politically divided among a considerable number of tribes; and that there were nine kings. (See *DWARF.*)

PYLOS, the name of three ancient towns of the Peloponnesus, on or near its western shore, one of which was in Hollow Elis, another in Triphylia, and the third and most important in Messenia, on the promontory of Coryphasium. The earlier city on the promontory was forsaken by the inhabitants after the close of the second Messenian war, and the promontory remained deserted until the Peloponnesian war, when in 425 B. C. it was fortified by the Athenian general Demosthenes. It became memorable for the defeat of the Spartans not long after, but at the close of the war passed again into the hands of the Lacedæmonians.

The town of Navarino is near the site of the old city, which is considered by most critics as the Pylos of Nestor. K. O. Müller, however, decides in favor of the Triphylian Pylos.

PYM, John, an English patriot, born at Brymore, Somersetshire, in 1584, died in London, Dec. 8, 1643. He was of a good family, and was educated at Pembroke college, Oxford, but left without taking his degree, and applied himself to the study of common law. He became a clerk in the office of the exchequer, entered parliament in 1614, and in 1620 became conspicuous as a leader of the country party. In 1621 he was one of the 12 commissioners sent to James I. at Newmarket in behalf of the privileges of parliament, and at the close of that year was sentenced with Coke, Philips, and Mallory to imprisonment for his opposition to the measures of the court. In the first parliament of Charles I. he was indefatigable in his support of the rights of the people, and in 1626 was one of the managers of the articles of impeachment against the duke of Buckingham. In 1639 he held communications with the commissioners sent to London by the Scotch Covenanters, and accompanied Hampden through the country to incite the people to send in petitions. In the short parliament of 1640 he was one of the most active members, and in the long parliament exerted great influence. On Nov. 11 he moved to impeach the earl of Strafford for high treason, and as one of the managers on the part of the house of commons he bore a prominent part in the proceedings which led to the execution of that minister. In the subsequent trial of Laud he also made a violent speech against the prisoner, and was the mover of the grand remonstrance, which enumerated the faults of the royal administration from the accession of Charles. He was one of the five members of parliament whom the king attempted in person to seize; and after the departure of Charles from London, he assisted in carrying on the executive branch of the government. Yet in 1643 he put forth a vindication of his conduct in answer to the charges brought against him, from which it was thought doubtful with which of the two parties then dividing the kingdom he would go. In November, 1643, just before his death, he was appointed lieutenant of the ordnance. He was buried in Westminster abbey.

PYNAKER, Adam, a Dutch painter, born at Pynaker, between Delft and Schiedam, in 1621, died in 1678. In his youth he resided for several years at Rome, where he acquired an ideal or pastoral style of landscape painting. His pictures contain charming effects of sunlight, with clear, warm skies, and trees and other natural objects are painted with a broad, free pencil, and great richness of color. The best of his works are of cabinet size, and many of these are owned in England.

PYRAMID (Gr. *πυραμῖς*), the geometrical term for any solid contained by a plane polygonal

base and other planes meeting in a point, applied to various monumental and temple structures of several nations. The most famous pyramids are those of the ancient Egyptians, and with few exceptions are the tombs of kings. The theories that they were astronomical monuments, or large storehouses, or, as Prof. Piazza Smyth holds, memorials of a system of weights and measures, intended to be universal, and built with the aid of divine inspiration, are not supported by the accounts of the ancients, nor by the Egyptian inscriptions and other testimony. The facts that the pyramids are found in the midst of a necropolis, that they contain sarcophagi and mummies, and that the inscriptions on the tombs of many priests mention as a special honor that the deceased officiated at the funeral services held at the pyramids, seem to prove that they are tombs and nothing else. As the Egyptian tombs have always borne one and the same character, and only the manner in which they were adorned varied with the tastes of the period, their age may be determined with great certainty. For the first eleven dynasties, or previous to about 3000 B. C., the tombs were in the form of a *mastaba*, or merely rectangular walls looking like unfinished pyramids, and their interior was richly decorated with sculptures and paintings, referring either to the life of the deceased or to the gods of the current religious system. During the middle empire, and until about 1600 B. C., the *mastaba* was superseded by small pyramids, and by the *speos* or halls cut into the rocks, and the divinities were seldom represented upon them. In the next period, until about 340 B. C., excavated tombs prevailed,

Mastaba of Meydoum.

and the statuary and images of the deceased were superseded again by those of a mythological nature. The pyramids are only enlarged *mastaba*, and belong as such to the first period. Each one was commenced over a sepulchral chamber excavated in the rock, and

to wall. It is 34 ft. 3 in. long, 17 ft. 1 in. wide, and 19 ft. 1 in. high. Over it are five small chambers (*l*), apparently built to shelter the larger room beneath from the weight of the masonry. The room is perfectly plain, and contains only a sarcophagus of red granite, 7½ ft. long, 3 ft. 3 in. wide, and 3 ft. 5 in. high, which is too large to have been introduced through the entrance passage, and must therefore have been placed in the room when this was built. It contained a wooden coffin with the mummy of the king, which disappeared when the pyramids were first opened and plundered. In the construction of the pyramids arrangements were made for blocking up the important passages with huge masses of granite, and the obstacles thus interposed have greatly impeded their exploration, and sometimes rendered it necessary to open new passages past the obstructions. It is probable that on account of these extraordinary precautions there are yet undiscovered apartments in the immense body of these structures. Niebuhr (1761), Davison (1763), the French expedition (1798), Hamilton (1801), Cavigliasi (1817), Belzoni (1818), and Col. Howard Vyse (1837) penetrated into the interior; but a forcible passage had been effected into the pyramid long before any of these visits. It is not improbable that the Egyptians themselves violated the tomb of Cheops, or that Cambyes entered it; but Arab historians record that the caliph Mamoun, in the beginning of the 9th century, forced his way into the pyramid in order to rob it of its supposed treasures. Unable to discover the hidden entrance, he caused a passageway to be broken through the masonry on the north side (*k*), and thus reached the passage coming from above. He found nothing but empty chambers, and a stone sarcophagus, containing another of wood, which held a richly decorated mummy.—The second pyramid, King Shafra's, stands on a base 33 ft. above that of the great pyramid, and in an excavation made for it in the rock. It measured originally 707 ft. 9 in. on the sides, and was 454 ft. 3 in. high; but these dimensions are now reduced respectively to 690 ft. 9 in. and 447½ ft. The angle of its slope is 52° 20'. The upper portion of its casing is still preserved, and persons can ascend this, though not without danger, especially if liable to become dizzy by losing sight of the lower portion of the structure. This pyramid has two entrances, one 37 ft. 8 in. above the base, and the other built out in front of the base, each leading by an inclined passage about 100 ft. in length to the same sepulchral chamber. This has a roof of the shape of the pyramid itself, and measures 46 ft. 2 in. by 16 ft. 2 in., and is 19 ft. 3 in. high. It contains a granite sarcophagus 8 ft. 7 in. long, 3½ ft. wide, and 3 ft. high. It was reached with great difficulty by Belzoni in 1818, who found a Cufic inscription recording the visit of a caliph and the opening by him

of the pyramid, A. D. 1196–7. The only remains met with were those of a bull. The third pyramid is only 354½ ft. square and 203 ft. high, but was originally 219 ft. high. It was explored in 1837 by Col. Vyse, who discovered several apartments, in one of which were a highly finished sarcophagus, a mummy case bearing the name of King Menkara, and the body of a workman. The last two are now in the British museum, but the sarcophagus was lost on the passage. This pyramid, though the smallest, is the best constructed of the three, and indeed the style of the work is more costly than that of any of the other pyramids of Egypt. In the same vicinity are six smaller pyramids, supposed to have been the tombs of some of the relatives of the kings who constructed the larger ones, and an immense number of tombs, some built up above the surface, some excavated in the rock, and some subterranean channels. Near the great pyramids is also the famous sphinx.—Of the other pyramids further S., the largest are of the Dashed group, of which there are five, two of stone and three of rough brick. One of the former is now reduced from 719½ to 700 ft. square, and from 342½ to 326½ ft. high, and the other is 616½ ft. square and 319½ ft. high. Abusir has a group of 14 pyramids, but many of them are small and mere heaps of rubbish, and only two are more than 100 ft. high. The Sakkara field of pyramids is adjacent to that of Abusir, and contains 17 pyramids more or less preserved. The most remarkable and largest in this group is the pyramid in steps, which possibly may once have been as smooth as the other pyramids, but none of the stones which formerly filled the gaps are to be seen. Its situation in the immediate vicinity of the oldest portion of the city, its rude construction, and its oblong rectangular form, originally measuring 351 ft. from N. to S. and 393 ft. from E. to W., indicate a very high antiquity. Its nucleus is still standing, and rises 190 ft. above the level of the desert, in five distinct portions. Instead of facing the cardinal points, it is turned 4° 35' to the east, which seems to show that its erection dates from a time when the rules for the exact astronomical construction had not been discovered. Egyptologists adduce many reasons for considering this pyramid either the tomb of Unephes or the oldest burial place of Apis. As both Apis bones and the remains of royal mummies have been found in it, the pyramid may have served first as the tomb of kings, and been afterward appropriated for the service of Apis. The other pyramids of Sakkara are almost entirely destroyed. One of them, an enormous mastaba, the Mastaba el-Faraon, has recently been entered by Mariette Bey, who discovered an inscription dedicating the tomb to King Unas, of the fifth dynasty. Among the minor fields of pyramids is that of Abu Roash, a village two hours from Gizeh, where there are three which evidently date from the earliest dynasties. But

generally speaking there is little of interest in the pyramids outside of Gizeh, Abusir, Sak-kara, and Dashoor.—Pyramids are frequently met with in the upper part of the valley of the Nile. There are many in Nubia about lat. 17° and 18° N., the sepulchres of the monarchs of Meroë and of Ethiopia; a single group N. of Jebel Barkal comprises 120. Others are met with in other ancient countries of the East. At Birs Nimrud is the step-shaped pyramid built by Nebuchadnezzar of bricks of different colors, known as the temple of seven spheres. This was 235 ft. high with a perimeter of 2,286 ft. The same monarch built the pyramidal brick structure of Mujellibe at Babylon, the ruins of which still remain. At Benares in India are also the ruins of pyramids; and others were built in ancient times at Peking, and again at Suka in Java. At Rome one was constructed 20 or 30 years B. C., in honor of C. Cestius, in imitation of the Egyptian monuments, and furnished with a sepulchral chamber; it is 120 ft. high on a base of 95 ft. diameter, built of hewn stone and marble-faced.—In Mexico are similar structures far exceeding in the area they cover the dimensions even of the great pyramid of Egypt. These monuments, called *teocallis*, literally “houses of God,” are pyramids in terraces with flat tops, and surmounted by a chamber or cell, which is the temple itself. They seem to be of all ages; that of Cholula is, according to tradition, as early as the Toltecs, while the great *teocalli* of the city of Mexico was finished only five or six years before the discovery of America by Columbus. (See CHOLULA, and Mexico, vol. xi., p. 483.) There are two pyramids at Teotihuacan, the largest of which is apparently a square of 645 ft. with a height of 171 ft., and there are others at Tezucuo of about the same dimensions, and like them divided into five or seven stories; but the most interesting of those yet brought to light is that of Xochicalco, on account of its sculptures and architectural ornaments. There are in Mexico also numerous pyramids of one story, but, like that of Oajaca, they are only devices to raise a temple to such a height as would enable the people to witness the ceremonies performed around it. While Egyptian pyramids are always tombs, and terminate in a point, without steps leading to the apex, the Mexican are always temples, and in terraces, with the upper platform crowned by a chamber or cell. Similar to the latter were the Assyrian pyramids, and the object of their construction was the same. In fact this form of temple has been found from Mesopotamia to the Pacific ocean. The resemblance has given rise to many theories on the racial connection of the builders, and Fergusson says: “If we still hesitate to pronounce that there was any connection between the builders of the pyramids of Suku and Oajaca, or the temples of Xochicalco and Boro Buddor, we must at least allow that the likeness is startling and difficult to account for on the theory of mere

accidental coincidence.”—See Vyse’s “Operations carried on at Ghizeh in 1837” (3 vols., London, 1840–’42), and Piazzzi Smyth’s “Life and Work at the Great Pyramid” (3 vols., Edinburgh, 1867). Excellent accounts of the Egyptian pyramids will be found also in Prokesch-Osten’s *Nilfahrt* (Leipsic, 1874), and in the new edition of Brugsch Bey’s *Histoire d’Égypte* (Leipsic, vol. i., 1875).

PYRAMUS AND THISBE, a youth and maiden of Babylon, celebrated in Ovid’s *Metamorphoses*. Their parents opposed their union, but the lovers, living in adjoining houses, found means to converse with each other through a hole in the wall, and once made an agreement to meet at the tomb of Ninus. There Thisbe arrived first, but, terrified by a lioness which had just torn to pieces an ox, she hid herself in a cave, and in her flight lost her mantle, which was rent by the lioness and soiled with blood. When Pyramus came and found the garment torn and bloody, he imagined that Thisbe had been killed, and thereupon fell upon his sword. When Thisbe returned and found the body of her lover, she slew herself with the same sword. This tragedy was enacted under a mulberry tree, the fruit of which, before white, has ever since been of the color of blood.

PYRENEES (Celt. *byrin*, a steep mountain), a mountain range of Europe, separating France from Spain, and extending from Capes Creus and Cervera on the Mediterranean to the S. E. angle of the bay of Biscay. The divisions of the two countries along the boundaries are, beginning at the east: in France, the departments of Pyrénées-Orientales, Ariège, Haute-Garonne, Hautes-Pyrénées, and Basses-Pyrénées; in Spain, Catalonia, Aragon, Navarre, and Guipúzcoa. The Pyrenees form the eastern half of the great northern barrier of the Iberian mountain system, their prolongation, the Cantabrian mountains, stretching to Cape Finisterre, the N. W. point of the peninsula. On the N. E. the Cévennes form a connecting link with the Alps. The direction of the chain is from S. S. E. to N. N. W.; its length is about 250 m., and its greatest breadth, excluding some of the remoter slopes, about 70 m. Near the middle its axis is deflected by an elbow, so that the line of the western half, if prolonged, would run about 20 m. to the south of the eastern portion. The Pyrenees generally consist of two parallel main ridges, from which transverse spurs extend far on either side. The southern ridge is the more elevated. The chain is higher in the eastern than in the western portion, and attains its greatest altitude and extension in the centre. Here the double range encloses the valley of Arran, in which the Garonne takes its rise. Other streams break through the northern ridge, but the southern presents a vast unbroken wall. This main ridge lies S. of the political boundary, so that the loftiest peaks and most elevated passes belong to Spain. The highest summits are not found along this crest, but occupy projections

to the south. The mass of the Maladetta, on the frontiers of Aragon and Catalonia, presents the two peaks of Nethou or Anethou and Maladetta, the former the culminating point of the chain (11,160 ft.). Mont Perdu (10,994 ft.), called in Spanish *las Tres Sorores*, and the Cylindre de Marboré lie further to the west. To the north of these are the Pic Posets and Pic de Vignemale, the latter the highest summit of the Pyrenees in France (10,791 ft.). Among the other principal summits are the Tour de Marboré, Pic Long, Montcalm, Pic de Néouvielle, Pic du Midi de Bigorre, and Pic du Midi de Pau, most of them upward of 10,000 ft. high. Mont Canigou (9,134 ft.), near the E. extremity of the range, on the meridian of Paris, forms a bold projection in France. The summit line, very uniform for long distances, has a mean elevation of about 8,000 ft., the passes being as elevated as those in the Alps.—A remarkable feature of the Pyrenees is the almost complete absence of longitudinal valleys, the great depressions running transverse to the chain. These frequently meet near the crest, and form passes called *cols* or *ports*. Many of the valleys terminate abruptly in huge basins (*cirques* or *oules*) enclosed by perpendicular walls of rock, and often one basin is continued by others on a higher level in the manner of an amphitheatre, the streams descending from one into the other in magnificent cascades. There are about 12 such falls in the basin of Gavarnie, the descent of one being 1,400 ft. In places the peaks rise almost perpendicularly for thousands of feet, and the grandeur of the scenery is unsurpassed even in the Alps. The snow line is about 8,500 ft. on the N. side, and on the S. side about 1,000 ft. higher. The snow does not appear in continuous fields, but is rather confined to the summits. Glaciers, the existence of which was until recently unknown, extend on the N. slopes of the highest peaks, above an elevation of 7,000 ft. There are a number of small lakes on the side of France. The passes of the Pyrenees are very numerous, but only a few are practicable for carriages. The principal, beginning at the east, are: the col de Pertus, the great highway between Perpignan and Gerona; the col de la Perche; col de Puymorens; port de Salo; the pass of Viella; the port de Venasque; the port d'Oo; the Brèche de Roland (9,193 ft.), almost inaccessible to the experienced smugglers of these mountains; the port de Gavarnie; the port de Canfranc, between Oléron and Jaca; the pass of Roncesvalles, between St. Jean-Pied-de-Port and Pamplona, memorable for the defeat of Charlemagne (see RONCESVALLES); and the pass of the Bidassoa, leading through Irun. The railroad from Bayonne to Vitoria passes the western extremity. The greater part of the range forms an unbroken watershed between the Mediterranean and the bay of Biscay, but the eastern portion belongs exclusively to the basin of the Mediterranean. The

principal rivers flowing toward the north are the Adour, Garonne, Ariège, and Aude. The southern slope is tributary to the Ebro, which receives the Segre and other considerable streams, and to the Llobregat. The Bidassoa, which traverses the charming valley of Bastan, forms the westernmost portion of the boundary line. The opposite sides of the Pyrenees present a great contrast. Toward Spain the range rises in a succession of abrupt terraces, whose rugged faces support a scanty and stunted vegetation. On the side of France the descent is much more gradual. Here the spurs enclose fruitful valleys enriched with fine pastures and orchards, and extensive forests stretch far up the slopes, affording good timber for ship building.—The primary geological formations are granite, forming the nucleus of the chain, micaceous schist, and primitive limestone, which are flanked by bands of clay slate, graywacke, and blue limestone. Oolitic and chalk formations occur, and trap, basalt, and porphyry appear in scattered masses. The mineral wealth of the Pyrenees is great, embracing iron, copper, zinc, and lead, but only the first of these metals is extensively worked. The Ariège rolls particles of gold. The mineral springs, mostly sulphurous, have long been noted, the best known being those of Eaux Bonnes, Eaux Chaudes, Bagnères-de-Bigorre, Bagnères-de-Luchon, Barèges, and St. Sauveur, all in France. The climate is comparatively mild. The forest trees include the oak, beech, fir, yew, and pine, and in the more elevated regions are found the rhododendron, daphne, and willow. Among the wild animals are the bear, wolf, lynx, and the izard, a species of wild goat. The inhabitants of the mountains are a vigorous race. Toward the east the little republic of Andorra has long maintained an independent existence. The Basques inhabit the westernmost portion of the chain.—The Pyrenees have repeatedly been traversed by hostile armies, from the time of Hannibal, who is supposed to have passed by the col de Pertus, to the present century. In 1813 they were the scene of encounters between Wellington and Soult. The treaty between Louis XIV. and Philip IV., known as the peace of the Pyrenees, was concluded on an islet of the Bidassoa, Nov. 7, 1659.

PYRÉNÉES, Basses. See BASSES-PYRÉNÉES.

PYRÉNÉES, Hautes. See HAUTES-PYRÉNÉES.

PYRÉNÉES-ORIENTALES, a S. department of France, consisting chiefly of the old province of Roussillon, bounded N. W. by Ariège, N. by Aude, E. by the Mediterranean, and S. by Spain; area, 1,591 sq. m; pop. in 1872, 191,856. It is traversed by lofty ridges of the Pyrenees, especially in the south, and there are vast plains in the east, and many rapid streams. It abounds in minerals, is celebrated for its fine wines and excellent merino sheep and mules, and has productive fisheries. Fruit, grain, hemp, and flax are raised; and coarse cloth, cutlery, and leather are manufactured.

The commerce is chiefly with Spain. It is divided into the arrondissements of Perpignan, Céret, and Prades. Capital, Perpignan.

PYRITES (Gr. *πυρίτης*, from *πύρ*, fire), a name given to yellow sulphuret of iron because it struck fire with steel. The German name *Kies* is similar to that for flint, *Kiesel*, and in the earliest firearms the powder was ignited by a piece of pyrites, the use of flints being later. It is now extended to sulphurets of other metals, and also to certain arsenides and double compounds of metals with sulphur. There are three kinds of iron pyrites: cubic or yellow, marcite or white, and magnetic pyrites. The first two are isomeric, having the formula FeS_2 , but are not isomorphous. Cubic pyrites crystallizes in several monometric forms, of which the cube, octahedron, and dodecahedron are the chief; while marcite belongs to the trimetric or rhombic system. Magnetic pyrites when pure has the formula Fe_3S_4 , and crystallizes in the hexagonal system. Cubic or yellow pyrites, or mundie as it is called in Wales, is found in all geological formations, from the most ancient crystalline to recent alluvial. Very large cubes have been found in some of the Cornish mines, dodecahedrons 6 in. in diameter in the island of Elba, and large octahedral crystals at Persberg in Sweden; in Connecticut, at Lane's mine in octahedrons, and at Orange and Milford in cubes in chlorite state; and in Pennsylvania, at Cornwall, Lebanon co., in cubo-octahedrons an inch in diameter. Cubic pyrites is largely used in the manufacture of coppers and sulphuric acid, and in Sweden for obtaining sublimed sulphur; and enormous quantities are exported from Spain to Great Britain. Yellow pyrites, from its resemblance to the precious metal, by which many have been deceived, is sometimes called "fool's gold." In the chemical works of Yorkshire "coal brasses," as pyrites is called, are exposed in their beds, where by the action of air and moisture they are converted into coppers; heat is developed during the process. In the coal fields subterranean fires are sometimes kindled by the conversion of masses of pyrites into coppers. At Quarreltown in Renfrewshire, Scotland, is a deep hollow where about 100 years ago the ground fell from a subterranean fire thus kindled. The conversion of pyrites into coppers is more conveniently conducted by roasting. (See **SULPHUR**, and **SULPHURIC ACID**.) Copper pyrites (calcoppyrite of Dana) is the common copper ore of Cornwall, where from 10,000 to 12,000 tons of copper are smelted from 150,000 to 160,000 tons of ore. It is a double sulphuret of copper and iron, containing sulphur 34.9, copper 34.6, iron 30.5. It crystallizes in the dimetric system, often in tetrahedrons. Copper pyrites in massive crystals occurs at Ellenville, Ulster co., N. Y., composed of sulphur 36.65, copper 32.43, and iron 31.25. Fire pyrites is found in the Cornish mines having the following composition: sulphur 30.0, tin 27.2,

copper 29.7, iron 13.1. Leucopyrite (Dana) is an arsenide of iron, and mispickite is a sulphuret of arsenic.

PYRMONT, a watering place of Waldeck, Germany, on the Emmer, 34 m. S. W. of Hanover. It has chalybeate springs, is the capital of the county of Pyrmont (pop. in 1871, 7,588), and contains a fine palace, a large bathing establishment, and a gas grotto emitting deadly vapors.

PYROLIGNEOUS ACID (Gr. *πύρ*, fire, and Lat. *lignum*, wood), also called pyroligneous and wood vinegar, the compound mixture of the volatile products from the destructive distillation of woody matters, which when purified yield acetic acid, wood naphtha, creosote, tar, &c. The method of producing it is noticed in the article **ACETIC ACID**, vol. i., p. 62, as also its use in the crude state for furnishing compounds useful as mordants in calico print works, as pyrolignite of iron, alumina, &c. It has been applied to various other uses, as for example, in medicine, as an antiseptic and stimulant in a wash for gangrene and ulcers, although at present the more definite products, such as carbolic acid, are preferred. Its antiseptic qualities have led to its use in preserving articles of food, as herrings and other fish. The process is auxiliary to drying in the shade, which precedes the dipping of the articles in the acid. Herrings first cured by a sprinkling of salt left upon them for six hours, and then drained, being immersed a few seconds in pyroligneous acid and then dried for two months, are in an excellent condition for preservation and retain a smoky flavor. The addition of a quart of the acid to the common pickle for a barrel of hams will cause the hams to acquire this flavor as if they had been smoked in the ordinary way.

PYROMETER (Gr. *πύρ*, fire, and *μέτρον*, measure), any instrument for determining degrees of heat higher than those which can be measured by ordinary thermometers. Pyrometers are required in the determination of the intensity of the heat of furnaces, and in ascertaining at what temperatures metals melt and chemical compounds are formed or are decomposed. They may be arranged, according to the principles on which they act, in the following classes: 1, pyrometers using the expansion of solids as a means of measuring high temperatures, of which class Daniell's is a type; 2, those using the contraction of baked clay, as Wedgwood's; 3, those employing the expansion of air, as Pouillet's, Regnault's, and Jolly's; 4, those using the known melting points of solids; 5, those depending on the chemical decomposition of solids, as Lamy's; 6, those measuring temperatures by heating a known weight of water, by allowing to cool in it a known weight of platinum or other metal, which has been heated to the temperature of the space or of the body to be tested, as Pouillet's; 7, those which determine temperatures from the measures of the strength of

thermo-electric currents produced by heating the junction of two different metals, as Becquerel's; 8, those which determine temperatures by the measurement of changes, produced by heat, in the electrical resistance of a length of platinum wire, as Siemens's; 9, those which use the expansion of the wave length of a sound, which traverses a tube placed in the furnace whose temperature is to be measured, as Mayer's. We will restrict our detailed description to the three pyrometers which experience has shown to be most trustworthy, viz.: Daniell's pyrometer, the air pyrometer, and Siemens's pyrometer. Of the others we will give only general descriptions of the principles on which they depend. 1. The first pyrometer based on the expansion of solids appears to have been invented by Musschenbroek about 1730. This instrument, which he called a "pyrometer," was formed of a metallic bar, fixed at one end, and connected at the other with wheel work which multiplied the motion of elongation caused by the elevation of its temperature. This was improved by others, who directed their efforts principally to the mechanism by which the motion was communicated to the index. Many of these contrivances are described in the article "Thermometer and Pyrometer" in vol. ii. of the "Natural Philosophy" published in the "Library of Useful Knowledge" (London, 1832). Daniell's pyrometer, called by its inventor "the register pyrometer," was first described in the "Transactions of the Royal Society" for 1830. It consists of two parts, the register, fig. 1, and the scale, fig. 2. The register is a solid bar of black-lead earthenware, A, highly baked. In the axis of this a hole is drilled, reaching from one end of the bar to within half an inch of the other extremity. In this cylindrical cavity is placed a rod of platinum or of iron, *a a*, $6\frac{1}{2}$ in. long. Upon the top of the bar rests a cylindrical piece of porcelain, *c c*, long enough to project a short distance beyond the extremity of the black-lead bar, to serve as an index. It is confined in its position by a ring or strap of platinum, *d*, passing round the top of the black-lead tube, which is partly cut away at the top; the ring is tightened by a wedge of porcelain, *e*. When it is exposed to a high temperature, the expansion of the metallic rod, *a a*, forces the index forward to a distance equal to the

FIG. 1.

Pyrometer,
Register.

difference in the amount of expansion between the metallic rod and the black-lead bar, and when cool it will remain protruded to the same distance, which will be greater or less according to the temperature; the exact measurement of this distance is effected by the scale, fig. 2. This scale is in-

dependent of the register, and consists of two rules of brass, *f g*, joined together by their edges accurately at a right angle, and fitting square upon the two sides of the black-lead bar. Near one end of this double rule a small brass plate, *h*, projects at a right angle, which

FIG. 2.
Daniell's Pyrometer,
Scale.

when the instrument is used is brought down upon the shoulder of the register, formed by the notch cut away for the platinum strap. To the extremity of the rule nearest this brass plate is attached a movable arm, D, turning at its fixed extremity upon a centre, *i*, and at the other end carrying an arc of a circle, E, the radius of which is exactly 5 in., accurately divided into degrees and thirds of a degree. Upon this arm, at the centre, *k*, another lighter arm, C, is made to turn, carrying upon the extremity of its longer limb a vernier, H, which moves on the face of the arc, and subdivides the graduation into minutes. The shorter arm, which is half an inch in length, crosses the centre, and terminates in an obtuse steel point, *m*, turned inward at a right angle. To use the instrument, the metallic rod is placed in the register, and the index is pressed firmly down upon its extremity and secured tightly by the platinum strap and the wedge. The position of the index is then read off on the scale, by placing the register in the reëntering angle for its reception, with the cross piece firmly held against the shoulder, and the steel point, *m*, resting on the top of the index, in a notch cut for it, which coincides with the axis of the rod. A similar observation, made after the instrument has been heated and allowed to cool, gives the value of the expansion. The scale of the pyrometer is compared with that of the mercurial thermometer, by observing the amount of expansion between two fixed points, such as the melting of ice and the boiling of mercury. In this pyrometer the temperature to which its register has been exposed is deduced from the amount of elongation of its metallic bar, on the supposition that the amount of elongation for an elevation of the same number of degrees is the same whether these degrees occur in the lower or in the highest regions of the thermometric scale. We now know, however, that the coefficient of expansion of a solid is not constant throughout the

range of available temperatures; hence, to obtain accurate measures with Daniell's pyrometer, it should be graduated by noting its indications at successive high temperatures, the thermometric values of which have been determined with an air thermometer. We should also be sure that successive heatings and coolings of the metallic bar do not change its coefficient of expansion. 2. Wedgwood's pyrometer, using the contraction of baked clay as a measure, consists of a metallic groove or gauge, the sides of which gradually converge; pieces of very pure clay are made into small cylinders, having one side flattened, and, being heated to redness, made just to fit the larger extremity of the groove. It is a property of clay permanently to contract and become harder by exposure to a high temperature, in consequence of its losing a portion of the water with which it is combined; and it was supposed that the amount of the contraction was exactly proportioned to the intensity of the heat to which it is exposed. The amount of contraction in the clay cylinders, after being exposed to the temperature which it was desired to measure, was easily determined by allowing the cylinders to slide from the top of the groove downward, till they arrived at a point beyond which they would not pass. Mr. Wedgwood divided the whole length of this gauge into 240 parts or degrees, each of which he calculated to be equal to 130° of Fahrenheit's scale; and the zero of his scale, indicating a red heat, corresponded, according to his experiments, to $1,077^\circ$. The difficulty of obtaining clay of uniform composition is of itself an almost insuperable objection to this method of estimating high temperatures; and it has been since ascertained that the observation upon which it is founded is not correct, for clay will contract as much by the long continuance of a comparatively low heat as by a short continuance of a high one. Hence the degrees of heat which Wedgwood's pyrometer has been applied to measure have been enormously exaggerated. Thus, Daniell's pyrometer shows that the melting point of cast iron is $2,786^\circ$, and the highest temperature of a good wind furnace about $3,300^\circ$; points which were estimated by Wedgwood at $20,577^\circ$ and $32,277^\circ$ respectively. In other words, Wedgwood's pyrometer gave figures nearly ten times higher than those obtained by Daniell's. 3. The expansion of air is used in pyrometers contrived by Pouillet, Regnault, and Jolly. If thermometers carefully made of any number of solids and liquids are all simultaneously exposed to the same successive elevations of temperature, it will be found that no two of them agree in their readings throughout the range of temperatures; but if we at the same time expose a set of thermometers made of the permanent gases (*i. e.*, of gases which have never been liquefied by pressure and cold), as oxygen, nitrogen, air, hydrogen, and carbonic oxide, we will find that they all agree in their readings.

For this reason, if for no other, these permanent gases should have the preference as bodies to form the expanding material of thermometers; but the theory of the thermodynamics of gases shows that from the expansion of these gases alone can we arrive at the knowledge of true temperatures. In short, it appears that while the coefficients of expansion of solids and liquids increase with the temperature, the permanent gases have the same coefficient of expansion, which also remains constant throughout the range of available temperatures. Indeed, men of science have agreed that the determination of temperature rests upon the assumption that the permanent, or, as they are now called, perfect gases, when subjected to a constant pressure, expand proportionately to the rise of temperature. This expansion, in the case of dry air, amounts for each degree centigrade to 0.003665 , or $\frac{1}{273}$ of the volume at 0°C. ; or what is the same, the pressure of a mass of air kept at a constant volume increases 0.003665 of its pressure at 0°C. for each rise of 1°C. in temperature. The simplest air thermometer, and the one best adapted to practical purposes, is that of Jolly. Its action depends on the law just given. A hollow globe of hard porcelain (platinum cannot be used by reason of its permeability to gases at high temperatures), A, fig. 3, communicates through the capillary tube E with the fixed vertical glass tube B. The tubes B and C and the connecting rubber tube contain mercury. The tube C moves upward and downward in a vertical direction, and carries with it the rubber tube D, and thus the surface of the mercury in B can always be brought to coincide with a mark, R, on the capillary tube E; so that the air in A and E is always observed under a constant volume after it has been heated to any temperature. The height of the mercury in C above R is read off on scales formed by cutting lines in the silvering of slips of glass mirrors placed behind the tubes C and R. When the centre of the pupil of the eye is seen in the plane passing through the surface of the mercury, we know that the line of sight is perpendicular to the length of the columns of mer-

FIG. 3.—Jolly's Air Thermometer.

ry, and that their true difference of levels has been correctly determined. To graduate the apparatus, the globe is surrounded with melting ice and the mercury is brought to the level R in the tube E; then the height of the barometer, b_0 , and the height, h_0 , of the mercury in C above the level R in E, are observed. We will call $b_0 + h_0 = H_0$. The heights b_0 and h_0 must be reduced to what they would be if the mercury in the apparatus were at 0° C. To measure any temperature, t , we expose the globe to this temperature for a length of time sufficient to heat uniformly the contained air, which is known to be the case when the mercury is stationary in B and in C. When this condition has been reached we obtain the height h , which is the difference of the readings of the levels of mercury at R and in C reduced to 0° C., and then read the height b of the barometer reduced to 0° C. Calling $h + b = H$, we have for the sought tempera-

ture $t = \frac{H + H_0}{.003665 H_0 - 3c H}$, in which formula $3c$

is the cubical expansion of the porcelain or other material forming the globe. In this formula the volume of air contained in the capillary tube E, up to the mark R, is neglected; but when the most accurate determinations are desired, it must be remembered that this portion of air in the pyrometer remains at or about the temperature of the air surrounding the part of the apparatus outside of the furnace. This temperature, which we will call t' , can be determined by means of a thermometer placed close to the tube E. Now to obtain the exact value of the temperature to which the globe has been exposed, we must add to the value of t as given above the following correction: $t \cdot \frac{v}{v'} \cdot \frac{H}{H_0} \cdot \frac{1}{1 + .003665 t'}$,

in which expression v represents the volume of the globe, v' the volume of the capillary tube from its junction with the globe up to the mark R, and t' the reading of the thermometer contiguous to the tube E. The ratio $\frac{v}{v'}$ is found

by determining the weight of the globeful of mercury up to the junction with it of the capillary tube, and the weight of the mercury in the capillary tube from its junction with the globe to the point R. If p be the weight of the mercury in the globe alone, and P the weight when both globe and capillary tube are filled up to the mark R, then $\frac{v}{v'} = \frac{P-p}{p}$. The

determinations thus made with the air pyrometer are universally accepted as standards with which to test all other methods of pyrometry, and the confidence placed in any pyrometer increases with the constancy and closeness of its agreement with the determinations made with the air pyrometer. 4. The range and accuracy of pyrometers using the melting points of solids are limited to the number of metals and definite alloys whose melting points have been determined with precision. The method

evidently gives only successive steps in elevation of temperature. Some of these steps according to the determinations of fusibility by Pouillet, who used an air pyrometer in his experiments, are given in the article FUSIBILITY.

5. The method of pyrometry by the chemical decomposition of solids is described in the article DISSOCIATION, and more detailed information may be found in Lamy's papers published in the *Comptes rendus* of the institute of France, vol. lxi., p. 347, and vol. lxx., p. 398.

6. In measuring high temperatures by the heating of water with heated platinum or other metal, according to Pouillet's method, we heat to the temperature to be measured a mass of the metal and then suddenly immerse it in a mass of water. Knowing the weight of the metal and its specific heat, and the weight of the water and its temperature before and after the immersion of the metal, we can compute the temperature of the latter before its immersion as follows: Let m be the weight of the metal, c its specific heat, and t its high temperature before immersion in the water. Let m' be the weight of the water, and t' its temperature before the introduction of the hot metal. The specific heat of water is unity.

The thin metallic vessel containing the water has a weight a , and its specific heat is b . The thermometer which shows the amount of elevation of temperature of the water by the heated metal has a portion of its length heated; let us call the weight of this part of the thermometer e , and its specific heat d . Finally let θ be the temperature of water, metal, vessel, and thermometer after the immersion of the heated metal, and at the moment they have all reached the same temperature. The metal in falling in temperature from t to θ has lost $t - \theta$ degrees, and a quantity of heat equal to $mc(t - \theta)$. The water in being heated from t' to θ has gained in temperature $\theta - t'$ degrees, and a quantity of heat equal to $m'(\theta - t')$. For a similar reason the vessel and the thermometer which partake of the heating of the water gain respectively $ab(\theta - t')$ and $ed(\theta - t')$. Hence the whole quantity of heat gained is $(m' + ab + ed)(\theta - t')$, or $m_i(\theta - t')$ if we make $m_i = m' + ab + ed$; m_i is then called the equivalent mass of water. In forming an equation between the quantity of heat received and the quantity of heat lost we have $mc(t - \theta) = m_i(\theta - t')$; whence t , the temperature of the heated metal, is expressed by

$t = \frac{m_i(\theta - t')}{mc} + \theta$. In using this method Pouillet

heated a ball of platinum in a crucible of the same metal, and the vessel containing the water had a wire cup in its centre into which the heated platinum mass was thrown. One of the elements of accuracy in this method is the precise knowledge of the specific heat of platinum at high temperatures. Pouillet made this a special study, and determined it up to $1,200^\circ$ C., using an air thermometer in obtaining the successive temperatures. To obtain

precise results with this method requires careful attention to several operations in the process, such as allowance for loss of heat by radiation from the water vessel during the experiment, and loss of weight of water by evaporation after weighing it and after the immersion of the heated platinum. We have also to guard specially against the projection of water from the apparatus by the generation of steam by the hot platinum. 7. Becquerel's pyrometer, based on the strength of thermo-electric currents produced by heating the junction of two different metals, is an improvement on a similar one devised by Pouillet. Two wires, one of platinum and the other of palladium, each about two metres long and of one square millimetre of section, are firmly tied together with fine platinum wire for a distance of about a centimetre from their ends. The palladium wire is enclosed in a porcelain tube, while the platinum wire is on the outside of this tube, which is itself enclosed in another tube of porcelain. The free ends of the palladium and platinum wires are soldered to copper wires which lead to a tangent galvanometer, and the junction of the copper and the palladium and platinum wires are immersed in melting ice to keep them at a constant temperature, so that no thermo-electric current can be generated in the apparatus except at the junction of the wires in the porcelain tube. In order to obtain the value of a high temperature, the end of the porcelain tube containing the junction of the wires is heated up to this temperature, and from the deflection of the galvanometer needle produced by the thermo-electric current thus produced we deduce the temperature of the junction of the wires. This apparatus, to be of any value, has to be graduated by exposing the junction of the metals along with an air thermometer to the same successive high temperatures, and thus fixing the relation connecting the indications of each apparatus with the corresponding temperatures. 8. Siemens's pyrometer is thus described by the inventor: "In order to realize a pyrometer by electrical resistance, it is necessary to rely upon the absolute measurement of the electrical resistance of a coil of wire, which must be made to resist intense heats without deteriorating through fusion or oxidation. Platinum is the only suitable metal for such an application, but even platinum wire deteriorates if exposed to the direct action of the flame of a furnace, and requires an external protection. The platinum wire used has, moreover, to be insulated and supported by a material which is not fused or rendered conductive at intense heats, and the disturbing influence of the varying resistance of the wires leading to the platinum wire has also to be neutralized. These various conditions are very fully realized by the arrangement represented in fig. 4. Thin platinum wire is coiled upon a cylinder of hard-baked porcelain, upon the surface of which a double-threaded helical groove is formed for its reception, so as to

prevent contact between the coils of wire. The porcelain cylinder is pierced twice longitudinally for the passage of two thick platinum leading wires, which are connected to the thin spiral wire at the end. In the upper portion of the porcelain cylinder the two spiral wires are formed into a longitudinal loop, and are connected crossways by means of a platinum binding screw, which admits of being moved up or down for the purpose of adjustment of the electrical resistance at the zero of the centigrade scale. The porcelain cylinder is provided with projecting rims, which separate the spiral wire from the surrounding protecting tube of platinum, which is joined to a longer tube of wrought iron, serving the purpose of a handle for moving the instrument. If the temperature to be measured do not exceed a moderate white heat, or say $1,300^{\circ}\text{C.} = 2,372^{\circ}\text{F.}$, it suffices to make the lower protecting tube also of wrought iron to save expense. This lower portion only, up to the conical enlargement or boss of iron, is exposed to the heat to be measured. Three leading wires of insulated copper united into a light cable connect the pyrometer with the measuring instrument, which may be at a distance of some hundred yards from the same. They are connected by means of binding screws at the end of the tube to three thick platinum wires passing down the tube to the spiral of thin platinum wire. Here two of the leading wires are united, whereas the third traverses the spiral, and joins itself likewise to one of the two former, which forms the return wire for two electric circuits, the one comprising the spiral of thin wire, and the other returning immediately in front of the same, but traversing in its stead a comparison coil of constant resistance. By this arrangement of wires the effect of the varying resistances of the leading wires is completely neutralized, for both battery circuits comprise the leading wires up to the distant coil, and all variations of resistance by temperature to which the leading wires may be subjected affect both sides of the balance equally. The measuring instrument may consist of a differential galvanometer if to the constant resistance a variable resistance be added. If the pyrometer coil were to be put

FIG. 4.—Siemens's Pyrometer, Coil Tube.

into a vessel containing snow and water, the balance of resistance between the two battery circuits would be obtained without adding variable resistance to the coil of constant resistance, and the needle of the differential galvanometer would remain at zero when the current is established. But on exposing the pyrometer to an elevated temperature, the resistance of its platinum coil would be increased, and resistance to the same amount would have to be added to the constant resistance of the measuring instrument, in order to reestablish the electrical balance. This additional resistance would be the measure of the increase of temperature, if only the ratio in which platinum wire increases in electrical resistance with temperature is once for all established. This is a question which I shall revert to after having completed the description of the pyrometric instrument. Although I have stated that by means of a differential galvanometer and a variable resistance (constituting in effect a Wheatstone bridge arrangement) the increasing resistance of the platinum spiral may be measured, it was found that the use of a delicate galvanometer is attended with considerable practical difficulty in iron works and other rough places where it is important to measure elevated temperatures, or on board ship for measuring deep-sea temperatures. I was therefore induced to seek the same result by the conception of an instrument which is independent in its action from tremulous motion, or from magnetic disturbance caused by moving masses of iron, and which require no careful adjustment or special skill on the part of the operator. This instrument is represented in fig. 5, and may be termed a chemical resistance measurer or 'differential voltmeter.' Faraday has proved that the decomposition of water in a voltmeter, expressed by the volume of gases V , is proportionate in the unit of time to the intensity I of the decomposing current, or that $I = \frac{V}{T}$. According to Ohm's general

law, the intensity I is governed by the electromotive force E , and inversely by the resistance R , or it is $I = \frac{E}{R}$. It is therefore $\frac{V}{T} = \frac{E}{R}$, or

$V = \frac{ET}{R}$; or the volume V would give a correct measure of the electrical resistance R , if only the electromotive force E and time T were known and constant quantities. But the electromotive force of a battery is very variable; it is influenced by polarization of the electrodes, by temperature, and by the strength and purity of the acid employed. The volume of gases obtained is influenced, moreover, by the atmospheric pressure, and it is extremely difficult to make time observations correctly. It occurred to me, however, that these uncertain elements might be entirely eliminated in combining two similar voltmeters in such a manner that the current of the same battery was divided between the two, the one branch

comprising the unknown resistance to be measured, and the other a known and constant resistance. The volume of gas V , produced in this second voltmeter, having a resistance R , in circuit, would be expressed by $V_1 = \frac{ET}{R_1}$, and we should have the proportion of $V : V_1 = \frac{ET}{R} : \frac{ET}{R_1}$; but E and T , being the same in both cases, may be struck out, and the expression will assume the simple form $V : V_1 :: R : R_1$. The constant resistance R of the one circuit being known, it follows that the unknown resistance R_1 is expressed by $\frac{R_1 V_1}{V}$; that is to say, by a constant multiplied by the proportion of gas produced in the two voltmeters irrespective of time, or strength of battery, or temperature, or the state of the barometer. The resistances R and R_1 are composed each of two resistances, namely, that of the principal coils, which we may term R or R_1 , and of the voltmeter and leading wires, which is the same in both cases, and may be expressed by y . The expression should therefore be written as follows: $V : V_1 = R + y : R + y$, R being the unknown quantity. The mechanical arrangement of the instrument will be understood from the diagram, fig. 5; and the

FIG. 5.—Siemens's Pyrometer, Resistance Measurer.

whole arrangement of the pyrometer, with its leading wire and resistance measurer, from the general view given in fig. 6. The voltaic resistance measurer, fig. 5, consists of two calibrated vertical tubes of glass of about three millimetres diameter, which are fixed upon a scale showing arbitrary but equal divisions. The upper ends of the tubes are closed by small cushions of India rubber pressed down upon

the openings by means of weighted levers, whereas the lower portions of the tubes are widened out and closed by plugs of wood, through which the electrodes in the form of pointed platinum wires penetrate to the depth of about 25 millimetres into the widened portions of the tubes. By a side branch the widened portion of each vertical tube communicates by means of an India-rubber con-

FIG. 6.—Siemens's Pyrometer, General View.

necting pipe to a little glass reservoir containing acidulated water, and supported in a vertical slide. In raising the weighted cushions closing the upper ends of the vertical tubes, and in adjusting the position of the small reservoirs, the acidulated water will rise in both tubes to the zero line of the scale. In turning a button in front of the tubes the battery current is passed through both pairs of electrodes, the one circuit comprising the permanent resistance R and the leading wires up to the pyrometer, and the other the leading wires and the pyrometer coil. If the resistance of the pyrometer coil should be equal to the permanent resistance R , then $R+y$ will be equal to $R+y$, and therefore $V=V_1$; but as the resistances differ, so will the volumes. Necessary conditions are, that both reservoirs are filled with the same standard solution of pure water with about 10 per cent. of sulphuric acid, that all of the electrodes are of the same form and size, and that their polarity is reversed frequently during the progress of each observation, in order to avoid unequal polarization. With these precautions, which involve no particular skill or knowledge of electrical observation on the part of the operator, very accurate results are obtained; but in order not to incur considerable error of observation, it is advisable not to continue the current, reversing the same, say twice, until at least 40 divisions of gases are produced in the least activated tube, which operation will occupy from two to three minutes, if a battery of from four to six Daniell elements is employed. The volumes V and V_1 being noted, after having allowed half a minute for the gases to collect after the current has ceased, the weighted cushions upon the tubes are raised in order to allow the gases to escape, when the water levels will immediately return to their zero position, to make ready for another observa-

tion. By inserting the observed values for V and V_1 into the expression above given, the unknown resistance R , can be easily calculated; but in order to facilitate the use of the instrument, I have prepared a table which gives at a glance the resistance due to any two observed volumes, the volumes V governing the vertical, V_1 the horizontal columns, and the resistance read off at the point of intersection. At each point of intersection the resistance is marked in black, and the corresponding temperature in red ink. It now remains only to be shown what is the relation between the resistance and temperature in heating a platinum wire. The researches of Dr. Matthiesen, who has made the latest investigation on the effect of temperature upon electrical resistance, are restricted to the narrow range of temperatures between 0° and 100° C., nor do they comprise platinum. He adopted the following general

expression for the pure metals: $R_t = \frac{R_0}{1 + \alpha t + \gamma t^2}$,

which, in determining the specific values of α and γ for each metal, gives a close agreement with observation between the narrow limits indicated, but is wholly inapplicable for temperatures exceeding 200° C., when the value t^2 commences to predominate and to produce absurd values for R_t . It was necessary for my purpose to undertake a series of elaborate experiments with a view of finding a ratio of general application. Coils of thin wire, of platinum, iron, copper, and some other metals, were gradually heated and cooled in metallic chambers containing the bulbs of mercury thermometers, and for higher temperatures of air thermometers, and the electrical resistances were carefully noted. The progressive increase of electrical resistance was thus compared directly with the increasing volume of a permanent gas (carefully dried) between the limits of zero and 470° C., and a ratio established which is represented by the formula $R_t = aT^2 + \beta T + \gamma$, in which T signifies total temperature counting from the absolute zero (272° C.), and a , β , and γ specific coefficients for each metal. According to this formula, the electrical resistance is a constant at the absolute zero, and progresses in a ratio represented graphically by a tipped-up parabola, approaching more and more toward a uniform ratio at elevated temperatures. Although the comparison with the air thermometer could only be carried up to 470° C., the general correctness of the ratio of increase just stated has been verified by indirect means in measuring progressive heats, and by comparison with the platinum ball pyrometer. It is important to mention here that great care must be exercised in the selection of the platinum wire for the measuring spiral, one of two samples, both of which were supplied by the same eminent makers, Messrs. Johnson and Mathey, having conducted 8.2 and the other only 4.7 times better than mercury at 0° C. The abnormal electrical resistance of some platinum wire is due

chiefly to the admixture of iridium or other metals of the same group, and it appears that the platinum prepared by the old welding process is purer and therefore better suited for electrical purposes than the metal consolidated by fusion in a Deville furnace. This pyrometer has already received several useful applications. Through its first application an important telegraph cable was saved from destruction through spontaneous generation of heat. Prof. Bolzani of Kazan has made some interesting applications of it for recording the temperature at elevated points and at points below the earth's surface. Mr. Lowthian Bell has used it in his well known researches on blast-furnace economy; and at several iron works pyrometer tubes are introduced into the heating stoves, and permanently connected with the office, where the heat of each stove can at all times be read off and recorded." Experience has shown that of all pyrometers, this is the best adapted for use in the arts. 9. By Mayer's pyrometer the expansion of the wave length of a definite sound, caused by elevation of temperature, is measured as follows: Opposite the mouth of an organ pipe is placed a Helmholtz resonator (see SOUND), which responds to the note of the organ pipe. The sonorous pulses, emanating from the organ pipe, enter the mouth of the resonator, and are thence sent through a tube terminated by a spiral tube of platinum. The pulses which have passed through this spiral tube are led to one of König's vibrating manometric flames. Another flame placed directly behind the former one is vibrated by pulses which have proceeded directly from the organ pipe. If the temperature in the organ pipe and in the spiral tube is the same (as is the case before the latter is introduced into the furnace), on viewing the flames in a rotating mirror we shall see both flames vibrating together and presenting the appearance of a deeply serrated band of light. Now, on slowly introducing the spiral tube into the furnace, we shall see the serrations, produced by the pulses which have traversed this tube, slowly sliding over the fixed serrations which are caused by the pulses led directly from the organ pipe to its special flame. After the air in the spiral tube has reached the temperature of the furnace and is stationary, we shall observe the serrations stationary also. From this observation of the number of movable serrations which have glided over any one fixed serration we can deduce the temperature of the furnace, as follows: Let t = temperature centigrade of the air in and around the organ pipe; t' = that of the air in the spiral or furnace tube; v = velocity of sound at temperature t ; v' = that of sound at temperature t' ; l = number of wave lengths in furnace tube at temperature t ; d = observed displacement of resonator serrations by an elevation of temperature $t'-t$. Then t' , the temperature of the furnace, will be $t' = \left(\frac{vt}{20 \cdot 16 (l-d)} \right)^2 - 272 \cdot 48$,

which gives t' in terms of v , l , and d . For fuller details concerning this method see the "American Journal of Science" for December, 1872. The advantage of this process is that no correction has to be made for barometric pressure, and the precision of the method depends alone on the accuracy of the determination of the coefficient .00367, which is the number arrived at by Regnault and Magnus for the expansion of air under a constant pressure; and this is one of the most certain constants we have in physics. Hence, theoretically, this method is as accurate as that of the air thermometer.—For further information on this important subject of pyrometry, see an article entitled *Pyrometrische Versuche*, by A. Weinhold, in Poggendorff's *Annalen*, vol. xxix., 1873. In this the author gives the bibliography of the subject and details of his experiments with all pyrometers to decide their relative values in practice.

PYROPHONE (Gr. *πῦρ*, and *φωνή*, sound), or **Flame Organ**, a musical instrument invented by Frédéric Kastner of Paris, in which the tones are produced by flames of hydrogen or illuminating gas burning in tubes of different sizes and lengths, arranged similarly to those in the common pneumatic organ. The production of musical tones by means of the little apparatus called the philosopher's lamp, in which hydrogen gas is burned in a tube, is a popular and familiar experiment; but it has been hitherto difficult to produce the same effects with illuminating gas in consequence of the carbon element interfering with the explosions of the gases. Kastner has overcome this difficulty by burning the gas in several small jets arranged in a circle, instead of a large one. He also made the discovery that when these flames were brought together the sound ceased, reappearing as soon as they were separated, and that the position of the flames should be one third the distance from the base of the tube. By a mechanical contrivance keys like those of a pianoforte or organ are connected with jointed arms, at the end of which the flames are burned in such a manner that they may be spread apart or joined together at will by a touch of the finger. The principles involved will be treated in the article SOUND. (See also FLAME.)

PYROPHORUS (Gr. *πῦρ*, fire, and *φέρειν*, to bear), a substance which takes fire on exposure to the air. This property is possessed by several substances and mixtures specially prepared. Finely divided metals, as iron when reduced from the oxide at the lowest possible temperature by a current of hydrogen, exhibit it in a remarkable degree. The effect appears to be produced in all cases by rapid combination of the oxidizable substance with the oxygen of the air. An excellent pyrophorus is produced by calcining in a close crucible 6 parts of lampblack mixed with 11 of sulphate of potash; the product is a mixture of carbon and sulphuret of potassium. Homberg's pyro-

phorus is made by stirring a mixture of equal parts of alum and brown sugar in an iron ladle over the fire till it becomes dry; then heating the same in a red-hot vessel nearly closed as long as a flame appears at the aperture. It is then removed from the fire, and carefully stopped until required for the experiment. Tartrate of lead heated to dull redness in a glass tube becomes a brown powder, which when shaken out into the air ignites. It is prepared from the solution of acetate or nitrate of lead by adding to it tartaric acid or a tartrate.

PYROTECHNY (Gr. *πῦρ*, fire, and *τέχνη*, art), the art of making fireworks for public exhibitions or for military purposes. Until the invention of gunpowder, and before the properties of saltpetre were understood, fireworks may be said to have been unknown in Europe; but the Chinese from an early period were skilful in true pyrotechnic works. In Europe the art was first cultivated by the Italians; and it was described by Biringucci Vanuccio in his work *De la pirotechnia* (1540). In France the subject was treated by J. Hanzelet in his *Traité des militaires* (1598), who recommended the use of the rocket in war, thus anticipating Congreve. The Chinese had from an unknown period employed the rocket as an offensive weapon, affixing to it a pointed barb like that of an arrow. Among the earliest pyrotechnic displays of much note in Europe were the exhibitions at Fontainebleau by Sully in 1606, and by Morel, commissary of artillery, in 1612. The rejoicings at the establishment of peace in 1739 gave occasion for splendid exhibitions at the hôtel de ville and the Pont Neuf in Paris and at Versailles.—The compositions prepared for fireworks are too numerous to be even named in this article, and reference can be made merely to the materials commonly employed, with exemplifications of the manner in which they are compounded in a few of the principal pieces. Gunpowder and its ingredients, nitre, sulphur, and charcoal, are the chief constituents of fireworks. Iron and steel filings and cast-iron borings, which must be free from rust, are used to increase the vividness of the combustion, and produce what is known as the Chinese “brilliant fire.” It is these which are thrown out by rockets as they explode, and produce the bright sparks as they meet the oxygen of the air. Copper filings and the salts of copper give a greenish tint to the fire; zinc filings, a fine blue; sulphuret of antimony, a light greenish blue with much smoke; amber, rosin, and common salt protected against dampness, are used to give a yellow fire; a red is produced by lampblack, and a pink by nitre in excess; the salts of strontia also give a red color, and those of barytes a green.—The most useful piece of fireworks is the sky rocket, employed as a signal, and under favorable circumstances visible for 30 leagues. As a warlike missile it will be treated under **ROCKET**. In exhibitions of fireworks the rocket is a luminous projectile, made

to dart upward with immense velocity and a loud hissing sound, and explode at the top of its flight. It is sent up singly or in volleys of great numbers together, and as they explode each one commonly discharges colored lights which descend in brilliant showers, or dart forth in every direction with the irregular motions of the so-called fuses and serpents. It is made of various compositions, which are packed in tubes formed by rolling paper hard round a cylindrical core. The match by which the rocket is to be fired is introduced into the cavity at the bottom, and the whole exposed surface of the composition forming the walls of the cavity is instantly ignited. The gaseous products, being violently ejected from the open end, react with equal force, carrying the rocket forward in the other direction. The movement would be extremely wild if not controlled by some regulator. This is furnished in a long balance stick firmly tied to the rocket and projecting several feet behind. It is made of light wood, and when it is set free after the explosion it rarely falls with sufficient velocity to do any harm. Long triangular pieces of pasteboard have been secured by the edge to the sides of the rocket as a substitute for the stick, and have also served to steady its movement. Among the decorations or garnitures for the rockets are stars, small cylindrical or cubical bodies variously compounded, as of 1 part of sulphuret of antimony, 2 of quartz, 2 of gunpowder, 15 of nitre, 6 of sulphur, and 2 of zinc filings. The materials, being separately pulverized, are mixed into a stiff paste with gum water or glue, made into the desired shapes, rolled in gunpowder, and dried.—Roman candles are cylindrical cases charged with stars alternating with a composition like that of the rockets, and with gunpowder. A small quantity of the composition is rammed into the bottom of the case, upon this a little gunpowder, and a star is then pushed down upon the powder. These charges are repeated in the same order until the case is filled. The end is then closed with a piece of match paper pasted round the outside and drawn to a point at the top. When this is fired the charges are shot at short intervals successively from the tube into the air. The effect is heightened by varying the composition and colors of the stars. A red fire adapted for this or other pieces may be made by mixing 4 parts of dry nitrate of strontia with 15 of pulverized gunpowder; or this may be varied with 40 parts of the strontia, 13 of sulphur, 5 of chlorate of potash, and 4 of sulphuret of antimony. The usual precautions should be observed in pulverizing and mixing the chlorate of potash. A green fire like that burned in theatres, which gives to everything upon the stage a death-like aspect, is produced by 77 parts of nitrate of barytes, 13 of sulphur, 5 of chlorate of potash, 3 of pulverized charcoal, and 2 of arsenic.—Bengal lights, also called blue lights, and used by ships as night signals,

are compounded of nitre 7 or 5 parts, sulphur 2, antimony 1; or for the sparkling ones, 4 each of sulphur and nitre, 1 of antimony, and 2 of fulminating composition (of fulminating mercury and gunpowder). The proportions of these ingredients may be variously modified from those given.—The published works on pyrotechny are mostly of the 17th and 18th centuries. Those of more recent date are: *L'art de faire à peu de frais les feux d'artifice* (Paris, 1828); *Manuel de l'artificier*, by A. D. Vergnaud (Paris, 1828); and "Pyrotechny," by G. W. Mortimer (London, 1853). The fullest work in English is "System of Pyrotechny, comprehending the Theory and Practice, with the Application of Chemistry," by James Cutbush (large 8vo, Philadelphia, 1825).

PYROXENE (Gr. *πῦρ*, fire, and *ξένος*, a stranger), a mineral species of Dana's augite section of the silicates, comprising numerous varieties. That to which the name was first applied, though found in the so-called igneous rocks, was supposed not to occur in modern lavas; whence the name. The species is interesting for its many varieties, which differ in physical characters and chemical constituents, and consequently have been separated by different mineralogists among several species. They were first brought together under the head of pyroxene by Haüy, who recognized the identity of the crystalline form common to them all; and though for a time the relationship among them was not admitted by chemists, it was at last found that the differences in their composition resulted from the substitution of one isomorphous element for another, and that one general formula might be used to express the combination of silicic acid with one or more of the following bases (one replaced by another in any proportions), viz.: lime, magnesia, protoxide of iron, or manganese, and sometimes soda. Alumina may also enter into the composition, replacing it may be a portion of silicic acid, without essentially changing the crystallization. Among the varieties comprised in this species are the augites, coccolite, diopside, sahlite, jeffersonite, and many others.

PYROXYLIC SPIRIT (also known as pyroligneous spirit or ether, wood spirit or naphtha, methylic alcohol, hydrate of methyle, &c.), a spirituous liquid, not a product of fermentation, but forming one of the most volatile constituents of pyroligneous acid, from which it is obtained in the process of purifying this acid by distillation; formula CH_4O . (See **ACETIC ACID**, and **NAPHTHA**.) When purified, wood spirit is a colorless liquid of a penetrating empyreumatic odor, and a disagreeable burning taste. It is very inflammable, burning like alcohol with a blue flame. It mixes with water, alcohol, and ether in all proportions. It boils at 150° , and at 68° its specific gravity is 0.798; at 32° , 0.8179. The substance was first recognized by P. Taylor in 1813; but its properties were first explained by Dumas and Peligot in 1835. In Great Britain wood naphtha, not

being subject to the excise duty, has been a valuable substitute for alcohol in various manufactures. By repeated rectifications over lime or chalk, and rejecting the latter portions in the distillations, it was obtained of strength varying from 80 to 90 per cent. of pure spirit, and of specific gravity from 0.87 to 0.83. From its property of dissolving the resins it was much used in the production of varnishes, lacquers, &c., and by the hatters for their solutions of shellac. The medical properties of wood naphtha have not been fully investigated, but it has been regarded as narcotic, sedative, and anti-emetic. At present it is little used, if at all. Berthelot has prepared wood spirit artificially by acting upon marsh gas with chlorine, and decomposing the chloride thus obtained by means of a solution of potash.

PYROXYLINE. See **EXPLOSIVES**, vol. vii., p. 35.

PYRRHA. See **DEUCALION**.

PYRRHO, a Greek philosopher, a native of Elis, born about 360 B. C., died about 270. He was successively a painter, a poet, and a companion of Anaxarchus, under whose patronage he joined the eastern expedition of Alexander the Great. He addressed a poem to that monarch, for which he received 10,000 pieces of gold. After the Indian campaign he returned to Elis, where he was made high priest, and for his sake a law was passed exempting philosophers from the payment of taxes. The only condition which he deemed worthy of a philosopher was that of suspended judgment. A man, he taught, should be indifferent to all external circumstances of life, and allow nothing to disturb his equanimity. Virtuous imperturbability was the highest aim of life, but truth, from a scientific point of view, unattainable. He developed his views only orally, and his name was bestowed on all who shared them. The Pyrrhonists were called inquirers, skeptics, ephectics, and doubters. His doctrines were expounded by Timon, Philo of Athens, Nausiphanes of Teos, and many others.

PYRRHUS, son of Achilles. See **NEOPTOLEMUS**.

PYRRHUS, king of Epirus, born about 318 B. C., killed at Argos in 272. He was the son of Æacides and Phthia, and traced his descent from Pyrrhus, the son of Achilles, and was also connected with the royal family of Macedon. His father having been dethroned by the Epirotes, Pyrrhus was rescued and brought to Glaucias, king of the Taulantians, an Illyrian people, who educated him with his own children. When Cassander's power in Greece was weakened, his protector restored Pyrrhus to his throne; but he was again expelled by the Epirotes, and fled to his brother-in-law Demetrius Poliorcetes, who was then in Asia. He distinguished himself at the battle of Ipsus in 301, and subsequently went into Egypt as a hostage for Demetrius. There he gained the good will of Ptolemy's wife Berenice, married

her daughter Antigone, and was furnished by the king with a fleet and troops to recover Epirus. He found Neoptolemus in possession of the throne, and the two agreed to hold it in common; but presently, to prevent his own destruction, Pyrrhus put Neoptolemus to death (about 295). He now interfered in the quarrels of Antipater and Alexander, the two sons of Cassander, and took the part of the latter on condition that he should receive Acarnania, Amphilochia, Ambracia, and some Macedonian districts. He then placed Alexander on the throne of Macedon, but the latter was soon dethroned by a powerful neighbor. Pyrrhus came and restored him to his kingdom. Soon afterward Demetrius, to whom Alexander had also applied for aid, put him to death and made himself king in his place. Hostilities soon arose between Pyrrhus and Demetrius, who had formerly been close friends. In 291 Thebes revolted from Demetrius; and while the Macedonian king was engaged in the siege of that place Pyrrhus marched into Thessaly, but was forced to retire. Thebes fell in 290, and Demetrius invaded Epirus in 289, leaving Pantauchus in Ætolia with a large force. Pyrrhus, advancing to meet Demetrius, but taking a different route, entered Ætolia, encountered Pantauchus, vanquished him in single combat, and routed his army. The next year he invaded Macedonia, and marched as far as Edessa, but was driven back, and soon after concluded a peace with Demetrius, who was now anxious to regain his father's dominions in Asia. Hereupon Seleucus, Ptolemy, and Lysimachus entered into an alliance, which they persuaded Pyrrhus to join, to attack the Macedonian king in his European dominions. Demetrius fled, and his kingdom was divided, a large share of Macedonia falling to Pyrrhus; but the Macedonians soon drove him out again, and put themselves under Lysimachus. In 281 an embassy from the Tarentines implored Pyrrhus to come over to Italy and assist the Greek inhabitants against the Romans. He set out in 280 with an army of 20,000 foot, 3,000 horse, 2,000 archers, 500 slingers, and a number of elephants; but a great storm scattered the fleet, and Pyrrhus arrived at Tarentum with only a small part of his army. There, while waiting for the dispersed ships to come in, finding the inhabitants indisposed to take their proper share in the war, he compelled them to enter the army, closed their theatres, and soon showed himself their master as well as ally. Failing to negotiate with M. Valerius Lævinus, the Roman general, Pyrrhus met him on the river Siris (now Sinno), and won a victory with the loss of a large number of his best troops. "Another such victory," he is reported to have said, "and I must return to Epirus alone." He now sent Cineas to Rome, offering peace on condition that the independence of the Italian Greeks should be recognized, and that the Samnites, Lucanians, Apulians, and Bruttians should regain the pos-

sessions they had lost in the war. The Roman senate rejected the terms, and Pyrrhus marched to within 24 miles of Rome, plundering the country as he went; but the arrival of the Roman army from Etruria compelled him to retire. He took the field again in the spring of 279, and gained a hardly won victory at Asculum. Few of his Grecian troops were now left; and, unable to obtain reinforcements from home, he was willing to conclude a truce in order to drive the Carthaginians from Sicily. Previously the Roman consuls Fabricius and Æmilius had sent back to Pyrrhus a servant who had deserted and promised to poison his master, and in return for this Pyrrhus released all the Roman prisoners. He now passed over into Sicily, and at first was so successful that the Carthaginians agreed to assist him against the Romans on condition of peace. He rejected this offer, but failing in an attack upon Lilybæum returned to Italy in 276. His fleet was attacked by the Carthaginians, and 70 of his ships were destroyed. In 275 he was routed near Beneventum by Curius Dentatus, and obliged to return to Epirus. In 273 he invaded Macedonia, of which Antigonus Gonatas, the son of Demetrius, was then king, and for the second time gained possession of that country. At the instance of Cleonymus, who had been excluded from the Spartan throne, he marched into Laconia in 272 with 25,000 foot, 2,000 horse, and 24 elephants. He arrived before Sparta at the close of day, but deferred the attack until the following morning. During the night the Spartans fortified themselves so strongly as to be able to hold the city until relieved by reinforcements. Taking up his winter quarters in Laconia, Pyrrhus was induced to interfere in the affairs of Argos, and in a conflict in the streets of that city he received a slight wound from a javelin. He was about to cut down the Argive who had attacked him, when the mother of the man hurled from the roof of a house a large tile which struck Pyrrhus on the back of the neck. He fell from his horse and was killed by soldiers of the enemy. Pyrrhus was regarded in subsequent times as one of the greatest generals that had ever lived. He wrote a work on the art of war, and his commentaries are quoted by Dionysius and Plutarch.

PYTHAGORAS, a Greek philosopher, founder of a philosophical, religious, and political association in southern Italy, born in Samos about 580 B. C., died probably in Metapontum about 500. He was the son of Mnesarchus, an opulent merchant, and according to some accounts was a disciple of Pherecydes of Syros, and of Thales and Anaximander. He is said to have spent 30 years in travel for the purpose of collecting all attainable knowledge, especially the esoteric doctrines of priests concerning the worship of the gods. Egypt, Arabia, Phœnicia, Judea, Babylonia, and even Gaul and India, are among the countries in which he is said

to have travelled. Herodotus traces the doctrine of metempsychosis and certain religious regulations of the Pythagoreans and Orphists back to the Egyptians, thus apparently implying that Pythagoras visited Egypt. Aristotle testifies that the mathematical sciences originated in Egypt, and were there cultivated by the priests; and according to Callimachus Pythagoras brought his mathematical knowledge from that country. On the authority of Apollodorus, Diogenes Laërtius ascribes to Pythagoras, among other things, the discovery of the relation between the hypotenuse and the sides of the right-angled triangle. It is easy to see that many of the statements made by later writers are mere embellishments and fables. Following Aristoxenus, Diogenes Laërtius again says that Pythagoras emigrated to Crotona in lower Italy, in order to escape the tyranny of Polykrates, and according to Cicero he came to Italy about 529 B. C. In Crotona he succeeded in winning the aristocratic party to his project of an ethical and religious reform, and in uniting them into a powerful political faction. Then it is said that about 20 years later the democratic party of Crotonians, under Cylon, obtained his banishment, and he withdrew to Metapontum, where he soon died.—It is generally held that Philolaus, a contemporary of Socrates, was the first to publish the Pythagorean system of philosophy; but though a considerable number of fragments that pass under his name are extant, their authenticity is very questionable. Böckh's collection of the fragments has been in part, if not wholly, rejected by Zeller, Rose, and others. The writings reported to come from Pythagoras himself are undoubtedly spurious. The most important indications of his doctrines are obtained from the writings of Aristotle. The fundamental doctrines are, that the essences of all things rest upon numerical relations; that numbers are the principle of all that exists; and that the world subsists by the rhythmical order of its elements. Everywhere in nature appear the two elements of the finite and the infinite, which give rise to the elementary opposites of the universe, the odd and even, one and many, right and left, male and female, fixed and moved, straight and curved, light and darkness, square and oblong, good and bad. The essence of number is unity, which is at once odd and even, and contains in itself in germ all the universe. It is both the form and the substance of all things, and identical with the Deity. Proceeding from itself it begets duality, and returning upon itself it begets trinity. Added to itself it produces the line; a third point placed on the other two gives the surface; and a fourth point placed on the other three gives the pyramid or solid. The quadrate or tetractys and the decade are, like unity, sacred numbers and first principles. The universe was produced by the breathing of the first principle into the infinite void of the world, which thus became

both finite and infinite, and therefore capable of development into a multiplicity of numbers or things. In the actual world every single whole is a unit, capable of further development by the vital process of breathing. Every abstract idea is a number, and material objects are symbols of numbers. Thus the Pythagoreans called justice a square number, intending by this to express the correspondence between action and suffering or retribution. There are five elements, earth, fire, air, water, and ether, represented respectively by the cube, pyramid, octahedron, icosahedron, and dodecahedron. The universe is a harmonious whole, consisting of ten great bodies revolving around a common centre. The doctrine of the harmony of the spheres was based on the idea that the celestial spheres were separated from each other by intervals corresponding with the relative lengths of strings arranged to produce harmonious tones. The centre is the sun, the seat of Jupiter, the principle of life, and the most perfect object in nature. That his hypothesis of the sun's immobility, and of the revolution of the earth around it, agrees with the facts of nature, was shown much later (about 280 B. C.) by the astronomer Aristarchus of Samos. The stars also are divinities, and men and even inferior animals are akin to the Supreme Being. The souls of men are moving numbers, light particles from the universal soul, capable of combining with any body, and destined to pass successively through several. They are chained to the body as a punishment, and dwell in it as in a prison. With the theory of metempsychosis he combined the doctrine of moral retribution. The reason and understanding have their seats in the brain; the passions are placed in the heart. Moral good is identified with unity, evil with multiplicity; virtue is the harmony of the soul and its similitude to God. The aim of life is to make it represent the beautiful order of the universe. The whole practical tendency of Pythagoreanism was ascetic (according to some accounts including abstinence from animal food), and inculcated a strict self-control, promoted, as is said, by a novitiate of silence, and an earnest culture, in which music was considered important. Though it seems to have been founded on the mysticism of numbers, yet Aristotle called the Pythagoreans a school of mathematicians.—See Schaarschmidt, *Die angebliche Schriftstellerei des Philolaus* (Bonn, 1864); Zeller, *Die Pythagorassage* (Leipsic, 1865); and Ueberweg's "History of Philosophy" (translated into English, New York, 1872).

PYRUS. See APPLE, ASH, and PEAR.

PYTHEAS, a Greek navigator of Massilia or Marseilles, who flourished about the age of Alexander the Great. He is said to have made two voyages, in one of which he visited Britain and Thule (perhaps Iceland), and in the second passed along the western and northern coast of Europe. He also wrote two

books, one of which, describing the ocean, was probably an account of his first voyage, and the other, entitled *Periplus*, of his second. Polybius and Strabo treat the statements of Pytheas with contempt; but in modern times it has become evident that he was a bold navigator and sagacious observer. He was the first who determined the latitude of a place from the shadow cast by the sun, obtaining the position of Massilia by the gnomon. He was also aware of the influence of the moon upon the tides. The few fragments of Pytheas now extant were collected by Arvedson (Upsal, 1824).

PYTHIA. See DELPHI.

PYTHIAN GAMES, one of the four great national festivals of Greece, held at Delphi, which was originally called Pytho from the serpent Python killed by Apollo near there. The legendary account attributed the origin of these games to Apollo, although there were traditions referring them to Amphictyon, Diomedes, and other heroes. At first the Delphians themselves decided the disputes and adjudged the prizes, but after the Crissæan war the management came into the hands of the Amphic-

tyons. Once, in Ol. 122, the games were held in Athens by the advice of Demetrius Poliorcetes. They appear to have lasted as long as the Olympic games, or till about A. D. 394. They were held in the Crissæan plain, which had a theatre for the musical contests, a race course, a stadium 1,000 ft. long, and probably a gymnasium, prytaneum, and similar buildings. Some ancient writers tell us that they were first called Pythian games in Ol. 48, when the Amphictyons assumed their management. Previously they had been held at the end of every eight years, but afterward at the end of every four. They were probably solemnized in the spring, and lasted several days. There were other Pythian games of less importance held in various places in Greece, Asia Minor, and Italy, where the worship of Apollo was established.

PYTHIAS. See DAMON AND PYTHIAS.

PYTHON (Daudin), a genus of large tropical, non-venomous serpents, replacing in the old world the boas of the new. The pythons differ from the boas in having four teeth in the intermaxillary bone, and in most of the subcaudal scales being in pairs. (See BOA.)

Q

Q, THE 17th letter and 13th consonant of the English alphabet. It corresponds with the Hebrew and Phœnician *koph*, and as it is seldom used except in conjunction with *u*, most grammarians are disposed to regard it as a superfluous letter whose place could be supplied by *k*. It does not occur in the Greek, old Latin, Slavic, Irish, or Saxon alphabet; but it was introduced into the Latin at a pretty early period. The words which are now written with a *q* were spelt by the ancient Romans with a *c*, as *anticus* for *antiquus*, *cotidie* for *quotidie*; and some words are still spelt indiscriminately with either, as *locutus* or *loquutus*. Varro and some other grammarians never consented to admit this letter into the Roman alphabet. Others regarded it not as a simple letter, but as a contraction of *cv* or *cu*; thus *quis*, according to them, was originally *cvis* or *qis*. The Anglo-Saxons for *qu* wrote *cw*. *Q* never ends a word in English, but it does in French, as *cinq*. It is sometimes used without *u* in the transcription of words from the Arabic and other oriental languages, to represent a peculiar guttural sound. The letters with which it interchanges are *c* and *k*. As a Latin numeral it stands for 500, or with a dash over it (\overline{Q}) for 500,000. Used as an abbreviation, it signifies *quantum*, *quod*, *quæ*, *que* (and), Quintus, &c.

QUA BIRD, or **QNAWK**. See NIGHT HERON.

QUACKENBOS, George Payn, an American educator, born in New York, Sept. 4, 1826. He graduated at Columbia college in 1843, spent a

year in North Carolina, and began to study law in New York. In 1847 he opened a private school in that city, and he continued to teach till 1868. He has been a contributor to various journals, and in 1848-'50 conducted the "Literary American." He has published many popular school books, including text books of rhetoric and natural philosophy, arithmetics, grammars, and elementary histories. He received the degree of LL. D. from Wesleyan university in 1863.

QUADI, a powerful ancient people of S. E. Germany, of the Suevic race. They inhabited the country between Mount Gabreta, the Hercynian forest, the Sarmatian mountains, and the Danube (portions of Bohemia, Moravia, and Lower Austria), their neighbors being the Gothini and Osi on the northeast, the Jazyges Metanastæ on the east, the Pannonians on the south, and the Marcomanni on the northwest. Of the last named they were allies. In the reign of Tiberius the Romans erected a kingdom of the Quadi, and gave the crown to Vannius; but in the reign of Marcus Aurelius the Quadi joined the German confederacy against the empire, and in 174 were on the point of destroying the imperial legions in a great battle when a sudden storm enabled the Romans to recover and gain a victory. The Quadi remained independent till their disappearance from history about the close of the 4th century.

QUADRANT (Lat. *quadrans*, a quarter), the fourth part of the circle or an arc of 90°, and hence an instrument employed for measuring

angles in any plane. The use of quadrants has been for surveying and for making astronomical observations, and especially in navigation for determining the meridian altitude of the sun, and through this the latitude of the observer. They have been constructed of a great variety of forms and dimensions adapted for their several uses; but at present the interest attached to them is historical only, as they have been entirely superseded either by the sextant or the full circle. The former, of more portable form than the quadrant, by the use of two reflecting mirrors doubles the angle included between the direct and reflected line of light, and thus with an arc of 60° or one sixth of the circle includes a range of 120° ; while the circle, on account of the symmetry of its form and the completeness of its graduated arc all around, secures greater exactness in its readings, and is less liable to the introduction of any unsuspected source of error. Ptolemy made use of a quadrant for determining the obliquity of the ecliptic. Tycho Brahe had a large mural quadrant (so called from its being suspended upon an axis secured in a solid wall of masonry) with which he observed altitudes, and also another on a vertical axis for measuring horizontal angles. The mural quadrants of that period were of 6 or 8 ft. radius, and for some time continued to be employed in the principal observatories. Sir Isaac Newton is said to have constructed a reflecting quadrant as early as 1672; but the first instrument of this character brought before the public was that afterward known as Hadley's, the invention of which was claimed by Godfrey, a mechanic of Philadelphia. This instrument, which has been in general use in navigation, is a graduated octant of 90 half degrees, reading as 90° . With the radial bars at each extremity of the arc it forms a triangular frame, which is made of convenient dimensions for holding in the hands. A movable radial bar or index revolves in the plane of the sector upon a pin passing through the centre. At the centre it carries a mirror, the face of which is perpendicular to this plane, and which in making an observation is turned toward the object, as the sun or a star, and at the other end it carries a vernier for subdividing the angles on the graduated limb. On the outer edge of the radial bar, back of the movable mirror, is the sight vane, which is directed across to a second mirror fixed upon the opposite bar, its plane perpendicular to that of the bar, and its face so adjusted that a ray reflected from the first mirror to the second is transmitted from this to the eye at the sight vane. Only half of the glass of the second mirror, called the fore horizon glass, is silvered, and consequently rays passing through it from any object, as the horizon at sea, meet the eye in a direct line; and if at the same instant, while the instrument is held to this position, the index is moved so as to bring the reflected image of the sun upon the silvered part of the glass and from this to

the eye, the reading of the vernier is the elevation of the sun above the horizon. Various other appendages are introduced in the quadrant, as a telescope for the sight vane, colored glasses for diminishing the intensity of the light, and a third mirror called the back horizon glass, with its sight vane, for taking a back observation. (For Gunter's quadrant, see GUNTER.)—In gunnery, the quadrant or gunner's square is a rectangular frame with a graduated arc between the two limbs. One of the limbs is extended beyond the arc, so as to be set into the mouth of the piece, the elevation of which it is to measure. A plummet suspended from the point of meeting of the two arms marks by the intersection of its line on the graduated arc the degree of elevation.

QUADRATURE, the finding of a square equal in area to that of any given figure. No mathematical problem has excited so great interest as the quadrature of the circle, or the determination of a square of the same area. As it is proved that the area of a circle is equal to that of a right-angled triangle, the altitude of which is the radius of the circle and the base its circumference, and as the side of the square of equal surface with the triangle is a mean proportional between the height and half the base of the triangle, the problem would be solved if the circumference could be immediately calculated from the radius which is known. Thus the question of the quadrature of the circle is reduced to finding the proportion between the diameter and circumference. Archimedes undertook the solution of the problem on the principle of calculating the peripheries of two polygons of many sides (as 96), one circumscribed about the circle and the other inscribed, between which must lie the circumference of the circle. He thus found that the ratio of the diameter to the circumference lay between $1 : 3\frac{1}{8}$ and $1 : 3\frac{1}{4}$, and he adopted the former, which is also expressed $7 : 22$. The Hindoos at some early period, certainly before any improvement was made upon this result in Europe, obtained the proportion $1,250 : 3,927$, or 3.1416 , which is much more exact than that of Archimedes. Ptolemy gives 3.141552 , which is not quite so correct. In modern times the first great step in extending this calculation was made by Peter Metius, a Hollander, and was published by his son Adrian Metius. By calculating from polygons of about 1,536 sides he found that the proportion was less than $3\frac{1}{128}$ and greater than $3\frac{1}{160}$; and presuming that the mean of these was nearer the truth than either limit, he happily hit thus by chance on a near approximation, and determined a ratio convenient for practical purposes, and easy to recollect from its terms being made up of successive pairs of the first three odd numbers, viz.: $113 : 355$. The error involved in this expression in a circle of 1,900 miles circumference is less than one foot. Ludolph van Ceulen (or Keulen), another Hollander, in 1590, about the same time that Metius

made his calculations, extended the calculation to 36 figures, which are engraved upon his tombstone in Leyden. These are 3.14159265358979323846264338327950289. The last figure is too large, and 8 would be too small. This was obtained by calculating the chords of successive arcs, each one being half of the preceding; for the above result this was carried out so far, that the last arc was one side of a polygon of 36,893,488,147,419,103,232 sides. The method of calculation was greatly simplified by Snell, who carried the computation to 55 decimal places by means of a polygon of only 5,242,880 sides. By other mathematicians the computation was carried on, reaching successively during the last century 75, 100, 128, and 140 places of decimals; and Montucla received from Baron Zach 154 figures, said to have been obtained from a manuscript in the Radcliffe library at Oxford, of the existence of which there is no other evidence. The figures, however, except the last two, have since been proved correct. (See Montucla, *Histoire des recherches sur la quadrature du cercle*, 1754.) Notwithstanding that Lambert in 1761, and still later Legendre in his *Éléments de géométrie*, proved that the ratio of the diameter to the circumference cannot be expressed by any numbers, the wish to satisfy those who still sought the exact expression of this ratio led other mathematicians to continue to add to these figures; and some must have derived a singular gratification in the computation itself and its never terminating result. In May, 1841, a paper was communicated to the royal society by Dr. Rutherford of Woolwich, presenting 208 figures of decimals, of which however 56 were afterward proved to be wrong, so that the series was not really carried beyond the result obtained from the Oxford manuscript. In 1846 200 decimals were correctly made out by Mr. Dase; and the next year 250 by Dr. Clausen of Dorpat. In 1851 Mr. William Shanks of Durham calculated 315 decimals, which Dr. Rutherford verified and extended to 350. Mr. Shanks soon carried these to 527 decimals, of which 411 were confirmed by Dr. Rutherford. Finally in 1853 Mr. Shanks reached the number of 607 decimals, and gave the result in his "Contributions to Mathematics" (London, 1853).—When it was made evident that the arithmetical expression was impossible, it was still hoped by many that the ratio might be determined by geometrical construction; and the bare possibility of this, which a few mathematicians have admitted, has given encouragement to some to seek the solution in this direction. But this, too, is now generally admitted to be impracticable.—Little benefit has resulted from the vast amount of time and labor that have been expended upon this famous problem. Wallis, investigating it at a time when the nature of the subject was not so well understood, and the investigation was consequently a proper one, was led to the dis-

covery of the binomial theorem; but most of those who have since interested themselves in the question understood too little of the mathematical sciences to avail themselves of any opportunity that might be presented of increasing the means of mathematical research. The academy of sciences at Paris in 1775, and soon after the royal society in London, to discourage this and other similarly futile researches, declined to examine in future any paper pretending to the quadrature of the circle, the trisection of an angle, the duplication of the cube, or the discovery of perpetual motion.

QUADRUNANA (Lat., from *quatuor*, four, and *manus*, hand), a division of the mammalia embracing the lemurs and monkeys or apes, and forming the highest order of Owen's subclass *gyrencephala*, so called from the generally prehensile nature of their four extremities. Although, on anatomical grounds, the term quadrunanous cannot be considered as strictly applicable to the members of this extensive order, it is nevertheless retained by the majority of naturalists in contradistinction to bimanous (two-handed), as restricted to man alone. The restoration of the Linnæan term *primates* (limited so as to exclude the *cheiroptera*) has of late been advocated by Prof. Huxley, as more conformable to the true nature of structural affinities, a view in which he has been sustained by St. George Mivart. This order, which has been conveniently divided into the three families of *strepsirrhini*, *platyrrhini*, and *catarrhini*, may be briefly defined as follows: Animals with a deciduate, discoidal placenta; clavicles complete; orbital ring completely circumscribed, and usually separated by an osseous septum from the temporal fossa; pollex (when present) often, and hallux generally opposable, the latter provided with a flat nail (except in orang, in which the nail is often wanting); cerebral hemispheres well developed and strongly convoluted, covering the cerebellum (except in *mycetes* and certain genera of the *lemuridae*, where the cerebellum is naked, and in the marmoset, where the external gyri and sulci are almost entirely wanting); stomach in most cases simple (complex in *sempithecus* and *colobus*) and furnished with cæcal appendages; teeth never in an unbroken series, but separated by a diastema.—The *strepsirrhini* (lemurs, aye-ayes, loris, galagos, potos, and indris) constitute the lowest family of the order, and inhabit portions of Africa, Madagascar, and some of the Asiatic islands. They are characterized by the twisted nature of their nostrils, and by the presence of a claw on the second digit of the foot. The aye-ayes (*cheiromys*), which seem to connect the lemurs with the lower rodents, form an abnormal group by themselves, by reason of the true rodent type of their dentition, which is, incisors $\frac{1}{1}-\frac{1}{1}$, canines $\frac{0}{0}$, premolars $\frac{1}{1}-\frac{1}{1}$, and molars $\frac{3}{3}-\frac{3}{3}=18$. The chisel-shaped incisors, moreover, agree with those of the rodents in growing from persistent pulps, but differ in being entirely in-

vested with a coat of enamel. The *platyrrhini*, American monkeys, are distinguished from the *catarrhini*, or monkeys of the old world, by several well marked characters, the most prominent of which is the broader development of the nasal septum. They also differ from them in the universal presence of a tail, which is generally prehensile, and in their dental formula, which is, incisors $\frac{2}{1}-\frac{2}{1}$, canines $\frac{1}{1}-\frac{1}{1}$, premolars $\frac{3}{2}-\frac{3}{2}$, and molars $\frac{3}{2}-\frac{3}{2}=36$. The marmosets form a sole exception to the general rule of dentition, in possessing but two molars in each side of both jaws, thereby reducing the total number of teeth to 32. The *catarrhini* have the dental formula corresponding to that of man, namely, incisors $\frac{2}{1}-\frac{2}{1}$, canines $\frac{1}{1}-\frac{1}{1}$, premolars $\frac{2}{1}-\frac{2}{1}$, and molars $\frac{3}{2}-\frac{3}{2}=32$. In this family the *meatus auditorius externus* is osseous, and the pollex is, with one exception (*colobus*), always opposable, circumstances which would be by themselves almost sufficient to separate the monkeys of the old from those of the new world. The *catarrhini* have been divided into the subfamilies *cynomorpha* and *anthropomorpha*. The former (baboons, macaques, &c.), which are essentially quadrupedal, are all possessed of ischial callosities, and in the majority of cases cheek pouches, serving as temporary receptacles for food, are present; the latter comprise the anthropoid apes, which, like the gorilla, assume a semi-erect attitude.—The skull in the quadrumana presents an extraordinary amount of divergence. It rarely assumes the rounded form observed in man, owing to the disproportionate size of the face as compared to that of the brain case. The facial portion attains its greatest development in the dog-faced baboon (*cynocephalus*) of Africa, where the jaws are prodigiously extended. The squirrel monkey (*chrysothrix*) of South America presents the opposite extreme, in having the face relatively smaller even than in man. In no instance does the absolute size of the brain approach that of the human subject. The cranial capacity, which is seldom as much as 26 or 27 cubic inches (orang and chimpanzee), reaches its maximum, 35 inches, in the gorilla. The number of vertebræ entering into the composition of the dorso-lumbar region of the spinal column is 17 in the orang, chimpanzee, and gorilla, 18 in *ateles* and *hylobates*, 22 in *nyctipithecus*, and 19 in the remaining monkeys; in the lemurs the number varies from 19 (typical) to 24 in *stenops tardigradus*. The caudal vertebræ are susceptible of a much greater variation, ranging from 3 in the Barbary ape to 33 in the spider monkey. The muscular system of the quadrumana closely resembles that of man, differing most widely in the long-tailed monkeys, where the muscles answering to the coccygeal in the human form are very greatly developed. The respiratory system presents some curious modifications, especially noticeable in the singular structure of the larynges. These are in many cases provided with air

sacs, numbering five in the howlers, whereby the intensity of sound is greatly increased.—The quadrumana are very extensively distributed over the tropical regions of both hemispheres. The *catarrhini* inhabit almost the entire continent of Africa, a large portion of southern Asia, and most of the islands constituting the Indian archipelago. It is a singular fact that Papua, an island rich in animal and vegetable forms, and presenting climatal and terrestrial conditions almost analogous to those of Borneo, Sumatra, or Java, should be entirely destitute of a monkey population; nor is it less remarkable that Australia has thus far furnished not a single representative of this family. But one species, the *macacus inuus*, is found native of Europe. Brazil is preëminently the home of the American monkeys, which however extend from Mexico to the 30th parallel of S. latitude. The West India islands present the same peculiarity as Papua. The limit of the vertical distribution of the quadrumana appears to be about 11,000 ft.—No unequivocal remains of a monkey have as yet been discovered in any formation dating anterior to the miocene. The best known fossil forms are the *dryopithecus* and *pliopithecus*, from the fresh-water deposits of France. It is worthy of remark that the present divisions of *catarrhini* and *platyrrhini* seem to have been as clearly defined in former ages as they are now, no representative of either family having as yet been found in the hemisphere other than that to which it is peculiar.—The exact position of the quadrumana is still unsatisfactorily determined. Their close relationship to the bimana is obvious, but, as Mivart remarks, it may be doubted whether, if the animal man had never existed, the highest point in the scale of perfection would have been conceded to the apes. The transition to the quadrumana from the lower orders is effected through the *galeopithecus*, a lissencephalous insectivore, inhabiting the Indian archipelago.—For detailed descriptions of the different families, see the articles APE, AYE-AYE, BABOON, CHIMPANZEE, GIBBON, GORILLA, LEMUR, LORI, MACAQUE, MARMOSET, MONKEY, and ORANG-OUTANG. See also Owen, "Anatomy of Vertebrates," vols. i. and ii. (1866-'8); Huxley, "Man's Place in Nature" (1863), and "Anatomy of Vertebrated Animals" (1872); Darwin, "Descent of Man" (1871); and the article "Ape" by St. George Mivart in vol. ii. of the "Encyclopædia Britannica" (9th ed., 1875).

QUÆSTOR (Lat., from *querere*, to seek), the name given to two classes of officers at Rome, the *quæstores parricidii* and the *quæstores classici*. The former have sometimes been confounded with the *perduellionis durumviri*, who had their origin in the time of the kings. Their duty was to bring accusations of capital offences, and to execute the sentence. After the establishment of the republic, *quæstores parricidii* were elected regularly every year by the curiæ. After the decemvirate they

were appointed by the centuries, and at the passage of the Licinian laws their functions were transferred to the *triumviri capitales*, ædiles, and tribunes. The *quæstores classici* had charge of the public money, registered and exacted fines, provided accommodations for foreign ambassadors and guests of the republic, took charge of the funerals and monuments of illustrious men buried at public expense, and kept the books in which the copies of the senate decrees were registered until the time of Augustus, when the originals were given into their hands. This office could only be held by patricians until 421 B. C., when the number, which previously had been two, was doubled, and the choice was not confined to either order; but it was not until ten years later that any plebeians were elected. Afterward the consuls in their campaigns were attended each by one quæstor, who originally took charge only of the sale of the spoils, but subsequently became the paymaster of the army. In 265 B. C. the number of quæstors was raised to eight, one of whom resided at Ostia and supplied Rome with corn. After this the number varied. By Sulla it was raised to 20, and by Julius Cæsar to 40. In 49 B. C. the latter also transferred the administration of the public treasury to the ædiles, subsequently to the prætors, and sometimes to the prefects of the treasury, and sometimes again to the quæstors. During the empire some quæstors were entitled *candidati principis*, and their duty was to read to the senate the communications of the emperor. From the reign of Claudius it became the custom of quæstors on assuming their office to give gladiatorial spectacles to the people, so that none but wealthy men were eligible; and the custom also prevailed in Constantinople after it became a capital of the empire.—Every prætor or proconsul was attended in his province by a quæstor, who, besides being paymaster of the army, raised the revenue not farmed out to the *publicani*, and controlled the latter also. When the prætor was away, the quæstor took his place, in which case he was attended by lictors. During the reign of Constantine, the title of *quæstor sacri palatii* was given to an officer in the imperial court, whose functions were somewhat analogous to those of a modern chancellor.—Any person who had held the office of quæstor was entitled to a seat in the senate, unless excluded by the next censors.

QUAGGA, a species of zebra, belonging to the asinine division of the horse family, and to the genus *asinus* as defined by Gray, characterized by a tail furnished with long hair only at the tip, the absence of horny warts on the hind legs, and a short and upright mane. The quagga (*A. quagga*, Gray) is about 4 ft. high at the shoulders; the neck and anterior parts of the body are dark brown, elegantly striped with broad black bands; the rest of the body paler brown, belly and legs white; a dark median line on the back extending to the tail. This beautiful species associates in large herds

with the gnu and ostrich, but not with other zebras, on the plains of S. Africa, and is rarely found north of the Gariep or Orange river; it is the most horse-like in structure of any of the group, having the form, light figure, and small head and ears of the horse, with the tail of the ass; Buffon regarded it as a hybrid

Quagga (*Asinus quagga*)

between a horse and a zebra. It is swift, and rather shy in its native state, strong, robust, and bold when attacked by hyænas or dogs; the voice resembles a barking neigh more than a bray, and has given to the animal the Hottentot name of quagga. It is the most easily domesticated of the zebras, and is docile, generally good-natured, and obedient, but disposed to kick at the sight of a dog. Its flesh, though coarse, is eaten by natives and hunters.

QUAHAUG. See CLAM.

QUAIL, the common name of several genera of the partridge division of gallinaceous birds. The American quails constitute the subfamily of *odontophorinæ* or *ortygina*, which have a short, high, and arched bill, compressed on the sides, with obtuse tip, the upper overhanging the lower mandible, and the latter with two teeth on each side concealed when the mandibles are closed; the wings moderate, concave, and rounded; tarsi generally slender, shorter than the middle toe, and covered with divided scales; toes long, the inner shorter than the outer; claws slightly curved and acute. In the genus *ortyx* (Steph.) the head is without crest, the bill broad, the third quill nearly as long as the fourth, fifth, and sixth, which are longest; tail short, broad, and rounded; toes slender, slightly united at the base by membrane; hind toe moderate and slightly elevated. There are about a dozen species, found in North and Central America and in the West Indies; they seek their food on the ground among the leaves, eating grains, seeds, berries, and insects, which they swallow with small pebbles or fine sand. The common quail, or Bob White (*O. Virginianus*, Bonap.), is about 10 in. long, with an alar extent of 15 in.; the

general color above is brownish red, especially on the wing coverts, tinged with gray and mottled with dusky on the upper back; chin, throat, forehead, and lines through the eyes

Common Quail (*Ortyx Virginianus*).

and along the sides of the neck, white; a black band across the top of the head, extending backward on the sides, and from the bill below the eyes crossing on the lower part of the throat; below white, tinged with brown anteriorly, each feather with black bands; the female has not the black marks, and the white on the head is replaced by brownish yellow. It is abundant in the eastern United States to the high central plains; the northern birds are largest and lighter colored, the southern with more black on the head, wings, and back; a smaller and more grayish variety in Texas has been separated as a species. The flight is rapid, low, and with numerous quick flappings. It takes to trees when alarmed, a flock dispersing in all directions and afterward coming together at the call of the leader. The males are very pugnacious, and in the breeding season utter the well known notes, "Ah Bob White," the first syllable rather low, but the others loud and clear; by some these notes are thought to resemble "more wet," and are therefore regarded as omens of rainy weather. The eggs are 10 to 18, pure white; the young run about as soon as hatched, but follow the old birds till spring, when they acquire their full plumage, pair, and breed; only one brood is raised in a season. They rest on the ground at night, arranged in a circle with their heads outward, so that each can fly off in a straight line, if alarmed, without interfering with the others; they are easily caught in snares and traps or driven into nets; they are difficult to raise from the egg, chiefly on account of the impossibility of obtaining the insects on which the young feed, but adults fatten well in captivity, eating grain, seeds, and berries; their flesh toward autumn is fat, juicy, and tender, white and highly esteemed; many perish from cold and hunger and from being

imprisoned under the snow during severe winters. There is great confusion about the name of this bird; it is called quail in the northern states, but in the middle and southern partridge; where the former name prevails the ruffed grouse is called partridge, and where the latter this grouse is styled pheasant; as neither the name quail, partridge, nor pheasant is properly given to any American bird, Mr. Baird proposes to call this species Bob White, and the other mountain grouse.—The genus *lophortyx* (Bonap.) has a crest of about half a dozen lengthened feathers, the shafts in the same vertical plane and the recurved webs overlapping each other; the bill weak; tail lengthened and graduated, of 12 stiff feathers, and nearly as long as the wings. Here belongs the beautiful California quail (*L. Californicus*, Bonap.), about 9½ in. long, with back and wings olivaceous brown, the secondaries and tertiaries edged with buff; breast and neck above plumbeous, the imbricated feathers on the latter with an edge and middle stripe of black; top of head brown, and crest black; throat black edged with white. This takes the place of the Bob White in California

California Quail (*Lophortyx Californicus*).

and Oregon.—The European quail belongs to the genus *coturnix* (Möhr.) of the partridge subfamily; in this the bill is short, elevated at the base and arched to the obtuse tip; wings moderate, with the second to the fourth quills the longest; tail very short, pendant, and mostly hidden by the coverts. There are about 20 species, scattered over Europe, Asia, and Australia, migrating in large flocks to warm regions in winter; some prefer cultivated districts, among tufts of grass, others rocky places, and others elevated table lands; the food and habits are as in other partridges. The European quail (*C. communis*, Bonn.) is 8 in. long, with an alar extent of 14 in.; the upper parts are variegated with reddish gray and brownish black, with whitish longitudinal streaks; throat of male dark brown, and

a double interrupted black band on the fore neck; throat of female yellowish gray; head completely feathered, with a white streak over the eyes. It is abundant in southern Europe,

European Quail (*Coturnix communis*).

India, and N. Africa; it was well known to the ancients, who employed it as a fighting bird for their amusement. The notes of the male, especially in moonlight nights in summer, are very clear and pleasing, and have acquired for it the specific name of *dactylosomans*. The Chinese quail (*C. Chinensis*, Edw.) is a smaller species, used in the East Indies as a fighting bird, and also for warming the owners' hands in winter.—The *turnicina* or bush quails of the old world have a moderate and usually straight bill, short wings, and tail almost concealed by the dorsal feathers; tarsi strong; toes usually three, long, and free at the base. In the genus *turnix* (Bonn.) the bill is curved, the tertials shorter than the primaries, and the first, second, and third quills equal and longest. There are more than 20 small species found in southern Europe, India and its islands, Africa, Madagascar, and Australia; they frequent open places near rivers, keeping near the ground when flying, and running rapidly among the grasses; the eggs are usually four. The *T. pugnax* (Lath.) of Java has the body varied with reddish black and white, beneath streaked with white and black, and throat black.

QUAKERS. See FRIENDS.

QUARANTINE (It. *quarantina*, Fr. *quarantaine*, a space of 40 days), a police regulation for the exclusion of contagious diseases from a city or state. Sanitary laws are founded upon the assumption that certain diseases depend upon a specific contagion, and their professed ends are to prevent the exportation, importation, and spreading of contagious pestilential disease. For the first we have a process of purification, for the second quarantine and lazarettos, and for the third lines of circumvallation and other modes of separation, seclusion, and restriction. The subjects of the

sanitary code are epidemic and pestilential diseases generally, of which cholera, plague, yellow fever, smallpox, typhus, and dysentery are the principal; but its operations have chiefly been directed against the supposed contagions of plague and yellow fever, and of late years have formed a feature in the sanitary police of domestic animals. Moses prescribed (Lev. xiii.) the most stringent precautionary measures to prevent the spread of disease. He not only ordered the lepers to be set apart from the rest of the people, but required that their clothes should be purified, and even that the garments belonging to the more aggravated cases should be burned. He gives explicit directions for the purification of the persons of those who have been cured of the disease, and also determines the time that the diseased shall dwell alone without the camp, as well as without their tent after being permitted to enter the camp. A peremptory sequestration of seven to fourteen days is also ordered for all those who had diseases of the skin. Long after Moses the religious laws were rigorously executed; and when the crusaders occupied Jerusalem, they established outside of the city an isolated place for the treatment of contagious diseases, called the hospital of St. Lazarus, whence the word *lazaretto*. Quarantine in Europe dates from the end of the 13th or the beginning of the 14th century, when leprosy prevailed in Italy and France. A military expedition returning from the Holy Land brought with it the Egyptian plague, which was looked upon as a new disease, and excited an unusual degree of attention from its great mortality and contagious character; it was soon discovered that those who avoided the sick escaped the disease. The first quarantine regulation originated with Viscount Bernabo of Reggio in Italy, and is dated Jan. 17, 1374. Yet the authorities of Florence are said to have used occasional precautions as early as 1348, and we see in Falasius that the emperors of the East had prescribed measures against those who arrived from places where plague prevailed, and it was at that time that the space of 40 days was fixed to observe them. The first quarantine regulations, founded on superstition and prejudice rather than reason and science, were most cruel and inhuman. The order of Bernabo required "every plague patient to be taken out of the city into the field, there to die or to recover." Their attendants were forbidden to associate with any one for ten days. Not only were these regulations strictly enforced, but in 1388 Bernabo forbade the admission of people from infected places into his territory, on pain of death. In course of time the benefits of these precautionary measures began to be understood and generally practised; but we have no account of any well defined legal code of regulations until about the middle of the 15th century, when the commerce of Venice was at its highest point. Robertson says this city

was not afflicted with plague while her commerce was limited or when it was dulled by the rivalries of the orientals; but when she had become strong enough to undertake conquests, when she covered the Mediterranean with her ships, and made commerce and war at the same time, she was invaded by a succession of plagues which originated in the Levant. In six centuries (from 901 to 1500) she had 63 epidemics. The Venetian senate in 1448 enacted a digest of laws known as the laws of quarantine. This system obliged all ships and individuals arriving from suspected places to undergo a term of probation before entering port and discharging their cargoes. The first organized lazaretto or pest house was erected in 1453 on the island of Sardinia, subsequently called *il lazaretto vecchio*; another was erected in 1468, called *il lazaretto nuovo*. All persons arriving from places where the existence of plague was suspected were detained there. The sick from the city laboring under the disease were sent with their families to the former station, and when cured were kept still 40 days longer in the latter. At a later period the republic of Venice established the first board of health, consisting of three nobles, who were appointed by the grand council. They were called the council of health, and were ordered to investigate the best means for preserving health and for preventing the introduction of disease from abroad. The efforts of this council not being entirely successful, in 1504 they were invested with the power of life and death over those who violated the regulations for health, and there was no appeal from their sentence. During the prevalence of plague in Italy about 1527 bills of health were first introduced, and in 1665 they had become general. Quarantines and lazarettos began to multiply along the shores of the Adriatic, and other nations established similar laws. Though certain preventive regulations had existed in England from a very early period, no regular system of quarantine was enforced until about 1710, when plague was raging in the towns on the Baltic. During the dreadful plague at Marseilles in 1720 the government appointed the celebrated Dr. Richard Mead to draw up quarantine regulations. Parliament, approving his suggestions, repealed the act of 1710, and passed an act establishing quarantine throughout the commercial kingdom. Yellow fever visited Philadelphia in 1699, and in 1700 the general assembly enacted the first quarantine law in this country, imposing a fine of £100 for every unhealthy vessel that landed. In 1701 a health law partly quarantine was enacted in Massachusetts. The first law on the subject in New York was passed by the colonial legislature in 1758. Congress passed "an act respecting quarantines and health laws," approved Feb. 25, 1799, which still stands upon the statutes. In 1831 cholera rode over all quarantine restraints; and these barriers being deemed antiquated,

reforms were suggested. On Aug. 18, 1847, a royal ordinance of France declared the first recognition of the truth, based upon the opinions of medical men, that many of the restrictions of quarantine were unnecessarily burdensome, and therefore they were abolished. Still other reforms were established by decrees of Aug. 10, 1849, and Dec. 24, 1850. Dupeyron suggested the idea of a sanitary congress. A convention of delegates from the principal countries in Europe met in Paris in 1851, and after a long discussion proposed an international code of quarantine laws, which was ratified by the nations represented. On the approach of cholera in 1865 the French government called an international sanitary conference at Constantinople. Since this discussion quarantine has been established on a scientific basis, and more in accordance with modern notions of liberty and justice.—Reviewing the history of quarantine, several periods may be distinguished. At first people, seized with terror, became panic-stricken; they wanted to be protected at any price. During this first period of superstition and terror, plague-stricken cities were burned; the sick were left alone to die; the shipwrecked from a suspected port were refused assistance; and physicians, afraid to approach their patients, threw bistouries at them from a distance in order to open their buboes. The second may be called the period of reaction. The atmosphere was considered as the vehicle of epidemics, and was supposed to transmit diseases to a great distance. Going to the opposite extreme, quarantines were declared useless. The cholera of 1830 furnished new arms to the adversaries of restrictive measures. The severe quarantines and cordons organized on a vast scale in Russia and Prussia, and other parts of central Europe, applied in the midst of dense populations, became mere propagating agents. With the conference of Constantinople the question enters on the third or scientific period, when the true principles of international hygiene became established. Why the term of 40 days was fixed upon as a proof whether people were infected, is not very clear. Some say it was chosen merely from superstitious notions, because people were accustomed to it in Lent; others that it arose from the doctrine of physicians in regard to the critical days of many diseases.—Communication with a country where a contagious disease exists may be interdicted by lines of troops or detachments posted from place to place. Some happy results may be cited in favor of these sanitary cordons applied at an opportune time and rigorously observed. Forts and villages in Orenburg and Astrakhan have been preserved from cholera by this means, as well as other towns in Russia, and also in Palestine and Arabia. The original lazaretto at Venice was the model for most of those forming part of the quarantine establishment in nearly all European ports. The old lazarettos are more dangerous than useful;

those of Ancona and the Dardanelles gave ample proof of this during the cholera epidemic of 1865. At the present day temporary lazarettos are considered the most desirable. Floating ones have lately been used in New York. In England there is no such thing as a lazaretto, though the quarantine act of July 28, 1800, provided for the erection of a lazaret on Chetney hill, in the county of Kent.—A rigorous quarantine consists in the sequestration and isolation of both ships and persons for a determined time, with disinfection of everything susceptible of concealing morbid germs. A quarantine of observation holds ship, crew, &c., under surveillance for a certain number of days; it may be enforced against a ship from a suspected port, or a ship in a filthy or unhealthy condition, although there may be no case of actual sickness on board. When a ship is about to sail, she is furnished by the consul of her country or other competent authority with a bill of health, which is her passport. It shows the sanitary state of the place of departure and of the points at which she has put in. A foul bill is delivered in a port where cholera, plague, or yellow fever prevails; a clean bill, where none of these diseases exist. The duration of quarantine is regulated by the nature of these documents. The declaration of the captain or master of the vessel, upon all incidents of the voyage having reference to the public health, is an act in certain circumstances of high importance. In 1865, upon false declarations made at Suez and at Constantinople, two captains obtained free entry into two ports; and the terrible consequences of these lying declarations are well known. Several countries where the cattle plague is regarded as exotic have enacted laws to prevent its spread; and an act of parliament is believed to have prevented its spread in Great Britain. Legal enactments of the same nature, only more stringent, prevail in France and Holland, and by the Ottoman government *peste bovine* is equally regarded with the plague, cholera, and yellow fever. An act of congress “to prevent the spread of foreign diseases among the cattle of the United States” was approved Dec. 18, 1865, and an act amending this, March 6, 1866. Cattle plague appeared simultaneously a few years ago in England and France, and the most rigorous methods were taken to strike at the root of the evil. In France it sufficed to kill 100 head of cattle to put an end to the progress of the epidemic. In England, owing to difference of opinion and insufficiency of legislation, things were allowed to take their natural course, and as many as 300,000 head of cattle were lost.—In the United States quarantine is exceedingly defective. Each state has laws of its own, which in many cases are absurd and conflict with one another. The law deserving most attention is that of the legislature of New York, Jan. 22, 1873, entitled “An act establishing a quarantine, and defining the qualifications, duties, and powers of the health

officer for the harbor and port of New York.” The quarantine establishment for the port of New York consists of warehouses, docks, and wharves, anchorage for vessels, a floating hospital, boarding station, burying ground, and residence for officers and men. Merchants are afforded facilities for overhauling and refitting vessels while in quarantine. Connected with the warehouses are apartments with appliances for special disinfection by forced ventilation, refrigeration, high steam, dry heat, and chemical disinfection. The boarding station for suspected vessels, arriving between the first day of April and the first day of November, is in the lower bay below the Narrows. Vessels are boarded as soon as practicable after their arrival, between sunrise and sunset. The anchorage for vessels under quarantine is in the lower bay, two miles from shore, and within an area designated by buoys. Quarantine applies against yellow fever, cholera, typhus or ship fever, and smallpox, and any new disease of a contagious, infectious, or pestilential nature. The floating hospital, with a capacity sufficient to accommodate 100 patients, is anchored in the lower bay from the first of May to the first of November; at other times it is anchored in some more secure place. The hospital at West bank, when so required, is used exclusively for yellow fever and cholera patients. The buildings on Hoffman island are used as a place of reception and temporary detention of persons who have been exposed to contagious or infectious diseases, but who are not actually sick. The health officer is the custodian of the quarantine establishment; his jurisdiction extends within the limits of the city and county of New York. In ascertaining the sanitary condition of a vessel he is authorized to examine under oath the captain, crew, and passengers, and to inspect the bill of health, manifest, log book, cargo, &c. Vessels liable to quarantine are required to discharge in quarantine, and be detained long enough thereafter for disinfection and aération, such detention not to exceed ten days unless the disease occurs or reappears during that interval, in which event the time is extended ten days. But no vessel or cargo which has been in quarantine is allowed to proceed to New York or Brooklyn without the approval of the mayor or board of health of those cities respectively. Filthy or unhealthy vessels are subject to quarantine for purification, not exceeding ten days. On infected or suspected vessels all clothing, personal baggage, cotton, hemp, rags, paper, hides, skins, feathers, hair, woollens, and other articles of animal origin, are subjected to an obligatory quarantine and purification. Molasses, sugar, and live and healthy cattle are subjected to quarantine at the option of the health officer. All other merchandise is exempted from quarantine and admitted without delay. The effects of persons who die in quarantine are taken in charge by the health officer, and if not claimed

by the rightful heir within three months are delivered to the public administrator of the city of New York. All persons who have died are interred without delay in the quarantine burying ground at Seguin's point. A vessel has the right to put to sea before breaking bulk, in preference to going into quarantine; but the health officer in such case indorses on her bill of health the circumstances under which she leaves port, the length of her detention, and her actual condition, and sends to the quarantine hospital such sick as may desire to remain. All passengers on board of vessels under quarantine are provided for by the master of the vessel. Any person violating the quarantine regulations, or who shall oppose or obstruct the health officer or any of his employees in the performance of their duties, is guilty of misdemeanor and punishable by a fine of not less than \$100, or by imprisonment not less than three nor more than six months, or by both such fine and imprisonment. Any person aggrieved by any decision of the health officer may appeal therefrom to the commissioners of quarantine, who constitute a board of appeal.—On June 6, 1872, congress passed a joint resolution providing for a more effective system of quarantine on the southern and gulf coasts. Dr. Harvey E. Brown of the army, being detailed in obedience to the resolution, made a thorough report, on the strength of which a national quarantine was proposed, and "An act to prevent the introduction of contagious or infectious diseases into the United States" passed the house of representatives, but did not become a law. Quarantine in France, under the new organization of 1850, founded upon the departmental division, comprises two elements: the one, active and responsible, representing authority; the other simply consultative, and representing the locality. The first is personified in an agent appointed directly by the minister, called director of health or principal agent, according as his duties are more or less circumscribed. The second is formed of a reunion of small functionaries and citizens taken from certain competent categories, and in particular from among the members of the council of hygiene and board of health. This organization is that of the large ports, which alone have a director and a special agent. In the others the service, reduced for economy to the strictest necessity, is done by secondary agents, principally employees of the custom house, who perform this service concurrently with their other functions. In India only limited measures have been taken to prevent the exportation of cholera. The "natives passenger act," promulgated by the government of India in 1858, only applies to the hygienic conditions and navigability of ships. The Dutch government, with a view to reducing the constantly increasing number of pilgrims who go from its possessions to Mecca, has established a regulation which may be beneficial in the future.—Many intelligent scientific ob-

servers have not only suggested sweeping and radical reforms in quarantine, but have questioned its utility and recommended its entire abrogation. In England, the general board of health, after close investigation, propose the entire discontinuance of quarantines, substituting for them a strict code of international hygienic regulations, and they unhesitatingly assert that quarantines are no public security. The doctrine of a specific contagion, so universally received when quarantines were first established, has lately undergone almost an entire revolution. Objections to new and more comprehensive measures of protection on the part of the general government of the United States cannot now be raised, as in the days of Jefferson, who in 1804, in a communication to congress on the state of the Union, protested against the adoption of a code of laws to prevent the introduction of yellow fever. The conference at Constantinople, although establishing the true principles of international hygiene, was occupied exclusively with their application to cholera. It is proposed that any resolutions adopted by a future convention should have for their common end the preservation of the healthy individual, and be founded upon a different principle: to regulate the isolation and sequestration of the human species, and to systematize the destruction of animals.

QUARLES. I. Francis, an English author, born at Stewards, Essex, in 1592, died Sept. 8, 1644. He was educated at Christ's college, Cambridge, studied law at Lincoln's Inn, was cupbearer for a while to the queen of Bohemia, and in 1621 went to Dublin, where he became secretary to Bishop Usher. Returning to England after several years' absence, he was appointed chronologer to the city of London, and devoted himself to literary labors until the rupture between the king and parliament, when his attachment to the royal cause plunged him into difficulties from which he never recovered. His best known writings are his "Divine Emblems" (1635) and "Enchiridion" (1641). The former, imitated from the *Pia Desideria* of the Jesuit Herman Hugo, consists of symbolical pictures with short moral lessons in verse; the latter is a collection of brief essays and aphorisms, in vigorous and occasionally eloquent language. Among his poetical works are: "Feast for Worms, or the History of Jonah" (1620); "Quintessence of Meditation" (1620); "Argalus and Parthenia" (1621); "History of Queen Esther;" an "Alphabet of Elegies" (1632), in memory of his friend Archdeacon Aylmer; "Hieroglyphics" (1638); "The Shepherd's Oracles" (1644); and "The Virgin Widow" (1649), a comedy. "The School of the Heart," attributed to him, is a translation of a Latin poem by Van Haeften of Antwerp, published anonymously in London in 1635. In most of these works he evinces strength of thought and considerable wit, but frequently becomes absurd and grotesque. His "Enchiridion" has been republished in Smith's "Li-

brary of Old Authors;" the "School of the Heart" and "Hieroglyphics" were reprinted in London in 1858, and the "Emblems" in 1859 and 1868. II. John, son of the preceding, born in Essex in 1624, died of the plague in London in 1665. He was educated at Oxford, assisted in defending the town against the parliamentarians, was a royalist captain, and retired to London after the king's overthrow. He wrote "Regale Lectum Miseriæ, or a Kingly Bed of Misery" (1648); "Fons Lachrymarum, or a Fountain of Tears" (1648); a continuation of the "History of Argalus and Parthenia" (1659); "Divine Meditations" (1665); and other works in verse and prose.

QUARTLEY, Arthur. See supplement.

QUARTZ, the most abundant of all minerals, existing as a constituent of many rocks, as the granitic and the micaceous and silicious slates, composing of itself the rock known as quartzite or quartz rock and some of the sandstones and pure sand, forming the chief portion of most mineral veins, and found interspersed in crystals and crystalline fragments throughout many rocks, and especially in their fissures and cavities. In composition it is silica, and when uncontaminated with any foreign intermixture it appears in clear transparent crystals like glass or ice. The presence of a little oxide of manganese gives these a violet tinge, and they are then known as amethyst. Other impurities which variously affect the appearance and properties of quartz, even in the small quantities in which they enter into its composition, are oxides of iron, aluminum, nickel, and other metals. Through all its varieties quartz is distinguished by the same chemical properties and degrees of hardness. This, which enables the mineral to scratch glass and to give fire when struck with steel, is represented by 7 of the scale of hardness. Its specific gravity is 2.5 to 2.8. Its lustre is vitreous, its colors various according to the impurities present, and its fracture conchoidal. It is fusible only at the intense heat of the oxyhydrogen blowpipe, and of the furnaces invented by Saint-Claire Deville; but it is readily fluxed with soda or lime. The quartz glass obtained by Deville, amounting to 30 grammes, possessed a density of only 2.2, or about one seventh less than that of the crystallized quartz from which it was melted. The colorless, transparent crystals impress circular polarization upon a ray of plane-polarized light. They exhibit double refraction when the object is observed through two faces which are not parallel to each other. Milk-white varieties often give a phosphorescent light when rubbed together in the dark. The primary form of the crystal, which is very rarely seen, is a rhomboid. The common form is a hexagonal prism terminated by hexagonal pyramids. The crystals occur in groups of great beauty and of all sizes up to single crystals of several hundred pounds' weight. In the museum of the university at Naples is a group weighing nearly

half a ton. In Milan is a crystal $3\frac{1}{4}$ ft. long and $5\frac{1}{4}$ ft. in circumference, estimated to weigh 870 lbs. A crystal in the museum of natural history in Paris is 3 ft. in diameter and the same in length, and weighs 800 lbs. Occasionally immense quantities of crystals are found collected in cavities in the rocks and in caves, loose and incrusting the walls. Such a collection, discovered at Zinken more than a century ago, produced 1,000 cwt. of rock crystal, which at that period, when the article was more highly valued than now, brought \$300,000. In the United States some rich deposits have been met with in the Ellenville lead mine, Ulster co., N. Y., and in some of the southern gold mines; and large groups of fine crystals have been found in Moose mountain, N. H., and in Waterbury, Vt. Little Falls on the Mohawk in New York is a famous locality for the purest transparent crystals of complete forms, and they are met with in other places also in the same region, occurring in the cavities of the calciferous sand rock, which overlies the Potsdam sandstone. Trenton Falls also furnishes perfect transparent crystals, which are sometimes 5 in. long and contain drops of water. These are occasionally recognized in quartz crystals of various localities. In St. Lawrence and Jefferson cos., N. Y., in the deposits of iron ore, quartz crystals are found of dodecahedral forms. In Orange co., 4 m. E. of Warwick, they occur in the primary form. Many of the varieties of quartz are known by other names, under which they have been particularly described in this work. (See AGATE, AMETHYST, CARNELIAN, CATS' EYE, CHALCEDONY, FLINT, GEODE, and JASPER.)—Clear crystalline quartz, called rock crystal, was in former times esteemed for ornamental objects. It was cut into vases, cups, lustres, &c., many of which are still preserved as curiosities. In the museum of the Louvre are great numbers of them, some belonging to the times of the ancient Greeks and Romans, but more generally of the period of the middle ages. The perfection to which the manufacture of glass and pastes has been brought and the cheapness of these materials have almost completely taken away the value of rock crystal, which requires a great amount of labor in its cutting and polishing, and after all is not really superior to the artificial products. But some use is still made of it, as for buttons, seals, breast pins, &c. It is procured from Madagascar, Switzerland, and Brazil. Very transparent specimens from the latter country are made into spectacle lenses called "Brazilian pebbles." They are superior to glass on account of their greater hardness. In Switzerland quartz veins which occasionally yield rich cavities of crystals are regularly mined for this product. From Madagascar large clear masses are received, which sell for from \$1 to \$10 a pound. When cut and set by the jewellers, the stone is commonly sold as white topaz, and sometimes as "California dia-

monds." Pure quartz is largely employed in the manufacture of glass, and is commonly obtained for this purpose in the form of sand; but metamorphic quartz rock of a granular structure and crumbly consistency is also used. (See GLASS.) Varieties of quartz of a cellular texture and great tenacity are used for mill-stones, the roughness and hardness of their surface and sharpness of the edges of the cells giving them a powerful grinding capacity combined with durability. (See BURSTONE.) Quartz veins with few exceptions form the gangues in which gold is found *in situ*, and it is probable that most of the gold which is obtained from alluvial and drift deposits came originally from the quartz veins. These gold-bearing quartz veins intersect various metamorphic rocks, such as chloritic, talcose, and argillitic schist, hornblende schist, gneiss, porphyry, and sometimes granite. (See GOLD.)

QUASSIA, a bitter drug, the properties of which, it is said, were first made known to Europeans by a negro slave named Quassi; the tree producing it was named *Quassia amara* by Linnaeus, and belongs to the *simarubææ*. Its wood is intensely bitter, and is sold in billets 2 to 4 in. in diameter. The supply of the drug originally came from Surinam; small quantities are exported to Europe, and under the name of Surinam quassia it is still used in Germany and France. Toward the end of the last century it was discovered that a tree known in Jamaica and neighboring islands as bitterwood and bitter ash had properties almost identical with the quassia; being much more abundant and in much larger pieces than the Surinam drug, this has almost entirely sup-

Bitterwood (*Picræna excelsa*).

planted it, and, though afforded by a different tree, the drug is called quassia. The tree is *picræna excelsa*, an allied genus in the same family with the other, having the general appearance of an ash, inconspicuous, greenish flowers, and black drupes the size of a pea.

The wood is imported in logs, sometimes a foot thick, with a smooth brittle bark; it is kept in the form of chips or turnings, which are nearly white when first cut, but become yellowish by exposure; it has no odor, and a strong, pure bitter taste, which is imparted to water and to alcohol. A neutral substance, to which the bitterness is due, has been separated and called quassine.—The properties of quassia are those of the simple bitters, and as a medicine it is adapted to cases of dyspepsia and the debilitated state of the digestive organs which sometimes succeeds acute disease. Animals have been killed by concentrated preparations of the drug. A sweetened decoction is sometimes used for poisoning flies. It is given in the form of cold infusion and in tincture. Bitter cups or quassia cups were at one time very popular; these are goblets turned from the wood, which quickly impart a bitter taste to wine, water, or other liquid placed in them. The decoction was formerly used in England by some of the brewers as a substitute for hops, but this is now prohibited under severe penalties.

QUATRE BRAS. See WATERLOO.

QUATREFAGES DE BRÉAU, Jean Louis Armand de, a French naturalist, born near Vallerangue, department of Gard, Feb. 10, 1810. He graduated doctor in medicine and science at Strasburg in 1829, published papers *Sur les aérolithes* (1830), and *De l'extraversion de la vessie* (1832), and, while assistant professor of chemistry in the medical faculty at Strasburg, wrote extensively for scientific periodicals. In 1838 he was appointed professor of zoölogy at Toulouse, in 1850 professor of natural history in the *lycée Napoléon*, in 1852 member of the academy of sciences, and in 1855 professor of anatomy and ethnology in the museum of natural history. Among his publications are: *Considérations sur les caractères zoologiques des rongeurs* (4to, 1840); *De l'organisation des animaux sans vertèbres des côtes de la Manche* (1844); *Recherches sur le système nerveux, l'embryogénie, les organes des sens et la circulation des annélides* (1844-'50); *Sur l'histoire naturelle des turets* (1848-'9); *Sur les affinités et les analogies des lombrics et des sangsues* (1852); *Souvenirs d'un naturaliste* (2 vols. 12mo, 1854; English translation, 2 vols., London, 1857); *Unité de l'espèce humaine* (1861); *Métamorphoses de l'homme et des animaux* (1862; English translation by H. Lawson, 1864); *Histoire naturelle des annélés marins et d'eau douce* (1865 et seq.); *Les Polynésiens et leurs migrations* (1866); *Rapport sur les progrès de l'anthropologie* (1867); *Le vers à soie* (1869); *Histoire de l'homme* (1869; English translation by Miss Eliza Youmans, New York, 1875); *Charles Darwin et ses procureurs français: étude sur le transformisme* (1870); *La race prussienne* (1871); and, in conjunction with E. T. Haury, *Crania Ethnica: Les crânes des races humaines décrits et figurés* (1875 et seq.).

QUATREMÈRE, Étienne Mare, a French orientalist, born in Paris, July 12, 1782, died Sept. 18, 1857. He was a pupil of Sylvestre de Sacy and Chézy. In 1809 he became professor of Greek literature at Rouen, in 1819 was called to the collège de France to teach Hebrew, Chaldaic, and Syriac, and in 1827 became professor of Persian at the school of the living eastern languages. To him is mainly owing the identification of the modern Coptic as a derivative of the language of the ancient Egyptians, which gave an important clue to the interpretation of the latter. He wrote *Recherches historiques et critiques sur la langue et la littérature de l'Égypte* (1808); *Mémoires géographiques et historiques sur l'Égypte* (1810); and *Observations sur quelques points de la géographie de l'Égypte* (1812). His editions and translations of Rashid ed-Din's *Histoire des Mongols en France* (1836) and Makrizi's *Histoire des sultans mamlouks en Égypte* (1837-'40) are of special value. His library was bought by the king of Bavaria and removed to Munich.

QUATREMÈRE DE QUINCY, Antoine Chrysostome, a French archaeologist, born in Paris, Oct. 28, 1755, died Dec. 28, 1849. In 1785 a paper *Sur l'architecture égyptienne* secured for him a prize from the academy of inscriptions; he was then engaged as a contributor to the *Encyclopédie méthodique*, for which he wrote a *Dictionnaire de l'architecture* (3 vols. 4to, 1786-1825). He took an active part in the events of the French revolution, and held several political offices under the republic, consulate, and empire, and after the restoration. In 1815 he was appointed superintendent of public monuments, and in 1818 professor of archaeology in the royal library; and he was secretary general of the academy of fine arts from 1816 to 1839. Among his voluminous works are: *Le Jupiter olympien* (fol., 1814), a restoration of the great work of Phidias; *De l'imitation dans les beaux arts* (1823; English translation by J. C. Kent, 8vo, 1837); *Histoire de la vie et des ouvrages de Raphaël* (1824); *Canova et ses ouvrages* (1834); and *Histoire de la vie de Michel-Ange* (1835).

QUEBEC (formerly LOWER CANADA or CANADA EAST), a province of the Dominion of Canada, situated between lat. 45° and 53° 30' N., and lon. 57° 8' and 79° 30' W.; area, according to the latest estimates, 193,355 sq. m. It is bounded N. by the Northwest territories and the portion of Labrador belonging to Newfoundland; E. by Labrador and the gulf of St. Lawrence; S. and S. E. by the gulf of St. Lawrence, New Brunswick, Maine, and New Hampshire, then S. by Vermont and New York; and S. W. and W. by the province of Ontario, from which it is mostly separated by the Ottawa river. The N. boundary line, formed by the height of land which separates the waters that flow into the river and gulf of St. Lawrence on the one hand from those that flow into Hudson bay and those that reach the Atlantic through the Labrador coast on the other, is

irregular, and has not been surveyed. The E. limit is a line drawn due N. and S. from Blanc Sablon bay (at the W. entrance of the strait of Belle Isle) to the 52d parallel. From Lake Temiscamingue, on the Ontario border, N. E. to Blanc Sablon bay, is about 1,050 m.; E. to the extremity of the Gaspé peninsula, 700 m.; S. E. to the angle formed by the boundary with Vermont and New Hampshire, 400 m. The general breadth N. and S. is about 125 m. E. of the mouth of the St. Lawrence river and about 250 m. W. of that. Exclusive of the cities of Montreal and Quebec, each containing three electoral districts, the province is divided into 59 electoral districts or counties, viz.: Argenteuil, Bagot, Beauce, Beauharnois, Bellechasse, Berthier, Bonaventure, Brome, Chambly, Champlain, Charlevoix, Chateauguay, Chicoutimi and Saguenay, Compton, Dorchester, Drummond-Arthabaska, Gaspé, Hochelaga, Huntingdon, Iberville, Jacques Cartier, Joliette, Kamouraska, Laprairie, L'Assomption, Laval, Lévis, L'Islet, Lotbinière, Maskinongé, Mégantic, Missisquoi, Montcalm, Montmagny, Montmorency, Napierville, Nicolet, Ottawa, Pontiac, Portneuf, Quebec, Richelieu, Richmond-Wolfe, Rimouski, Rouville, Shefford, Sherbrooke, Soulanges, St. Hyacinthe, St. Johns (St. Jean), St. Maurice, Stanstead, Témiscouata, Terrebonne, Three Rivers (Trois Rivières), Two Mountains (Deux Montagnes), Vaudreuil, Verchères, and Yamaska. Quebec (pop. in 1871, 59,699) is the capital and Montreal (pop. 107,225) the commercial metropolis of the province. There are two other cities, Three Rivers (pop. 7,570) and St. Hyacinthe (pop. 3,746). Lévis (pop. 6,691), Sorel (5,636), Sherbrooke (4,432), Joliette (3,047), and St. Johns (3,022) are incorporated towns. Other towns and villages, having each more than 1,000 inhabitants, are Aylmer, Berthier, Beauharnois, Buckingham, Chicoutimi, Coaticook, Farnham, Fraserville, Hull, Lachine, Laprairie, L'Assomption, Longueuil, Montmagny, Rimouski, St. Jérôme, and Terrebonne. The population of the province in 1676 was 8,415; in 1734, 37,252; in 1770, 91,078; in 1780, 127,845; in 1827, 423,378; in 1831, 511,920; in 1844, 690,782; in 1851, 890,261; in 1861, 1,111,566; in 1871, 1,191,516. Of the last number, 596,041 were males and 595,475 females; 1,104,401 were born in the province, 7,018 in Ontario, 2,746 in other parts of British America, 12,371 in England, 35,828 in Ireland, 11,260 in Scotland, and 14,714 in the United States; 929,817 were of French, 123,478 of Irish, 69,822 of English, 49,458 of Scotch, 7,963 of German, and 148 of African origin; and 6,988 were Indians, chiefly Algonquins, Iroquois, Abenakis, Hurons, Micmacs, Malicetes, Montagnais, and Nasquapees. There were 191,862 persons 20 years old and over (107,782 males and 84,080 females) unable to read, and 244,731 (123,926 males and 120,805 females) unable to write; 180,615 occupied dwellings, 213,303 families, 1,630 deaf and

dumb persons, 1,023 blind, and 3,300 of unsound mind. Of the 341,291 persons returned as engaged in occupations, 160,641 belonged to the agricultural, 25,507 to the commercial, 21,186 to the domestic, 65,707 to the industrial, and 15,376 to the professional class, and 52,874 were unclassified. A large portion of the inhabitants live in the region S. of the St. Lawrence and W. of the meridian of Quebec. This region is known as the "eastern townships," though the term in strictness is confined to the district between the Chaudière and Richelieu rivers in the rear of the settlements immediately along the St. Lawrence. E. of Quebec the settlements S. of the St. Lawrence extend to and around the extremity of the Gaspé peninsula, but for the most part they are closely confined to the shore. N. of the St. Lawrence and below the mouth of the Saguenay there are only a few scattered fishing settlements, and above that the settlements for the most part extend only a few miles from the river. In the valley of the Ottawa, however, and on the upper Saguenay and around Lake St. John, there is a considerable population. A great majority of the inhabitants speak the French language, but English may also be used in legislative and judicial proceedings, and the laws must be printed in both languages. The greater part of the English-speaking population is in the cities of Montreal and Quebec, in the S. part of the eastern townships, and in the valley of the Ottawa. Recently efforts have been made to colonize the unsettled portions of the province; colonization societies have been formed to aid settlers, and roads have been built by the government; but the access of population from abroad has not been equal to the emigration from the province to the United States.—The region S. of the St. Lawrence is generally hilly; N. of that river the country is for the most part rocky and mountainous. The Notre Dame mountains, a continuation of the Green mountains of Vermont, stretch E. from the meridian of Quebec, passing through the interior of the Gaspé peninsula to near its extremity, and attaining in places a height of 3,000 or 4,000 ft. This elevation is reached near the Cape Chatte river, in a portion of the range called the Shickshock mountains. The Laurentian mountains, on the north of the river St. Lawrence, extend from the Labrador coast to the Ottawa river above the city of that name. They lie near the margin of the St. Lawrence as far up as Cape Tourmente near the city of Quebec, above which they recede N., passing 60 m. behind Quebec and 30 m. behind Montreal. This range, between Quebec and Lake St. John, where the rivers are 3,000 ft. above the level of the St. Lawrence, attains an elevation of from 4,000 to 5,000 ft. above the sea, but in general its height is much less. The province has a coast line on the gulf of St. Lawrence, not including indentations of the land, of 1,164 m. There are many small bays on the coast N. of the river St. Lawrence; the

principal ones S. of it are Gaspé bay and the bay of Chaleurs. The latter, lying between the province and New Brunswick, includes with the mouth of the St. Lawrence the peninsula of Gaspé. Except those in the St. Lawrence, the principal islands belonging to the province are Anticosti (2,500 sq. m.), at the mouth of that river, and the Magdalen islands in the gulf. The St. Lawrence, flowing in a N. E. direction for more than 500 m. through the province, and rendered navigable the entire distance by canals around the rapids, is the great avenue of commerce. Vessels may ascend from the gulf of St. Lawrence to the head of Lake Superior. It contains numerous islands, the largest of which are Orleans (69 sq. m.) just below Quebec, Montreal (169 sq. m.) at the mouth of the Ottawa, and Isle Jésus (85 sq. m.) N. of Montreal and separated from it by a narrow channel. The largest tributaries of the St. Lawrence are from the north; the principal ones from the south, proceeding down the stream, are the Chateauguay, which rises in New York and is navigable for a considerable distance by bateaux; the Richelieu, also called the Chambly, Sorel, or St. Johns, 80 m. long, the outlet of Lake Champlain; the Yamaska, 90 m. long; the St. Francis, more than 100 m. long, which receives the Magog, the outlet of Lake Memphremagog, and empties into the St. Lawrence at Lake St. Peter; the Nicolet, 60 m. long; the Bécancour, 70 m. long; the Chaudière, 120 m., emptying into the St. Lawrence a few miles above Quebec; the Etchemin, 50 m. long; the Rimouski; the Métis; the Matane, 60 m. long; and the Cape Chatte river, entering the St. Lawrence at Cape Chatte. By means of the Richelieu river, Chambly canal, Lake Champlain, the Champlain canal, and the Hudson river, there is continuous water communication between the St. Lawrence and New York. The largest tributaries from the north, lying wholly within the province, are the Saguenay and the St. Maurice. The former flows out of Lake St. John, and after a course of upward of 100 m. joins the St. Lawrence 120 m. below Quebec. It has an average width of about three fourths of a mile, with high precipitous banks. It is navigable by the largest vessels to Chicoutimi, 75 m. above its mouth. During the summer the Saguenay is much visited by tourists, and the ancient port of Tadousac at its mouth is a favorite watering place. The St. Maurice rises in the height of land, and after a course of more than 400 m. discharges into the St. Lawrence at Three Rivers. Its banks are generally high, and it contains numerous falls, and has many important tributaries. It is navigable for a few miles at its mouth; the navigation is then interrupted for about 40 m., above which there is a navigable stretch of 75 m. Other important tributaries of the St. Lawrence from the north are the Portneuf, the Betsiamites or Bersimis (navigable for a considerable distance), the rivière aux Outardes,

and the Manicouagan, below the Saguenay; the Jacques Cartier (60 m. long), the St. Anne (70 m.) and the Batiscan (50 m.), between Quebec and the St. Maurice; and the Du Loup, the Maskinongé, and L'Assomption (100 m. long), above the St. Maurice. The Ottawa river rises in the W. part of the province, and has a tortuous course, first in a N. W., then in a W. direction, of 300 m. to Lake Temiscamingue on the Ontario border, below which, flowing S. E., it forms the boundary between the two provinces for 400 m., emptying into the St. Lawrence just above the island of Montreal. It is navigable along the border for more than 250 m., the rapids and falls being avoided by means of canals. The only portion of the province of Quebec W. of the Ottawa is the angle made by that river with the St. Lawrence, comprising the counties of Soulanges and Vaudreuil. The chief tributaries of the Ottawa from this province are the Keepawa, 120 m. long, which enters Lake Temiscamingue; the Du Moine, having about the same length; the Gatineau, 400 m. long, which joins the main stream nearly opposite the city of Ottawa, and is navigable by canoes for more than 300 m.; the Du Lièvre, 260 m. long; the North Petite Nation, 95 m.; the Rouge, 90 m.; and North river or rivière du Nord, 160 m. The E. part of the province is drained by numerous streams that flow into the gulf of St. Lawrence from the north. Among these, proceeding toward the east, are the Moisie, Manitou, Magpie, St. John, Mingan, Natashquan, St. Augustine, and Esquimaux or St. Paul. In the south, portions are drained by tributaries of the St. John and the Restigouche, the latter flowing into the bay of Chaleurs and forming a part of the boundary with New Brunswick. Its chief tributary from Quebec is the Matapediac. The chief tributaries of the St. John are the St. Francis, which forms a part of the boundary with Maine, and the Madawaska, which flows into New Brunswick. The principal rivers of the peninsula of Gaspé are the Grand and Little Cascapediae and the Bonaventure, which empty into the bay of Chaleurs; the Mal Baie, St. Johns, York, and Dartmouth, flowing into the gulf of St. Lawrence from the west; and the Madeleine and St. Anne, emptying into the gulf from the south. There are numerous lakes, particularly in the northwest, where the country is covered by a network of them, the rivers here being little else than chains of lakes. The most important ones S. of the St. Lawrence are Memphremagog, partly in Vermont; Mégantic, which discharges through the Chaudière river; Témiscouata, discharging through the Madawaska river; and Matapediac, discharging through the river of the same name. The largest in the province is Lake St. John, 80 by 25 m. in extent, about 120 m. N. of Quebec, in which the Saguenay river takes its rise. This lake lies in an extensive valley, and receives numerous large streams, some of which

rise in the height of land. The largest of its tributaries are the Peribonka, from the northeast; the Mistassini and Ashuapmouchouan or Chamouchouan, from the northwest; and the Ouatouchouanish, Ouatouchouan, Metabetchouan, Kushpahiganish, and Belle Rivière or Kushpahigan, from the southwest and south. Lake St. Peter is an expansion of the St. Lawrence between Montreal and Quebec.—The geological formations that occur in the province are the Laurentian, Silurian, Devonian, and carboniferous. The region N. of the St. Lawrence is occupied by the lower Laurentian, with small areas of upper Laurentian around Lake St. John and N. of Montreal, and a narrow belt of lower Silurian along the river bank above Quebec. S. of the St. Lawrence the country consists of different groups of the lower Silurian, followed S. E., along the borders of New Hampshire, Maine, and New Brunswick, by smaller tracts of middle and upper Silurian, with areas of the Devonian in the Gaspé peninsula. Anticosti is occupied by the lower and middle Silurian. The Magdalen islands are of carboniferous formation below the coal measures. Gold is found on the Chaudière river, and mining has been carried on in Beauce co., but with little success. Copper is found in large quantities in the eastern townships, where mines are in operation. Iron ore is widely diffused, and is mined to some extent. An ore of excellent quality is obtained near the St. Maurice river. Lead, silver, platinum, zinc, &c., have also been found. Quebec abounds in magnificent scenery, especially on the lower St. Lawrence and Saguenay. Among objects of interest may be mentioned the Chaudière falls in the Ottawa, the falls of the Chaudière river, the falls of Montmorency near the city of Quebec, and the falls of the St. Anne 20 m. below it.—The climate is healthy, but subject to extremes of temperature. The winters are cold, with a clear and bracing air; the summers are warm. Winter commences about the end of November and lasts till the middle of April. The plateau of Lake St. John is sheltered on the north and east by mountains, and has a climate like that of Montreal. The shores of the Gaspé peninsula are exposed to the cold winds and fogs of the gulf. In the N. E. part of the province, comprising a portion of the peninsula of Labrador, the climate is much colder than elsewhere. The following table gives the results of observations for a series of years at Montreal (lat. 45° 31') and Quebec (lat. 46° 49'):

SEASON.	MONTREAL.		QUEBEC.	
	Mean temperature.	Rainfall, inches.	Mean temperature.	Rainfall, inches.
Autumn.....	47·3°	10·35	44·6°	6·65
Winter.....	18·1	1·91	13·8	0·25
Spring.....	42·5	5·72	87·6	2·70
Summer.....	69·5	9·80	66·0	9·66
Year.....	44·8°	27·26	40·5°	19·26

The highest temperature observed at Montreal during the period was 96.1°; lowest, -28°. The highest observed at Quebec was 94.4°; lowest, -30.5°. The annual precipitation of rain and melted snow at Montreal is 37.54 inches; at Quebec, 31.84 inches.—The soil of the valley of the St. Lawrence and of the “eastern townships” is generally fertile. The townships are a fine grazing country, and much attention is paid to the raising of cattle and wool. On either side of the Notre Dame mountains, W. of the Gaspé peninsula, there is much good soil. The peninsula is generally rocky, but contains considerable arable land, particularly along the bay of Chaleurs. On the upper Saguenay and around Lake St. John there is an extensive region suited to agriculture, and the basin of the St. Maurice contains many fertile valleys. In the basin of the Ottawa also there are extensive tracts of good land. The Labrador portion of the province is rocky and sterile, and its climate too severe for agriculture. The greater portion of the province is covered with forests, the most common and important trees being the red and white pine. Other species are the ash, birch, beech, elm, hickory, black walnut, maple, cherry, butternut, basswood, spruce, fir, and tamarack. Hard wood is most common S. of the St. Lawrence. Lumbering is very extensively carried on, particularly on the tributaries of the Ottawa, St. Maurice, and Saguenay. The timber lands are leased by the government for a term of years for a certain bonus and annual rents. Oats, potatoes, and hay are the largest crops. Wheat, barley, rye, peas, beans, buckwheat, Indian corn, turnips, flax, apples, tobacco, hops, &c., are also grown. Except in the S. W. portions, the climate is too cool for Indian corn. The island of Montreal is noted for the excellence of its apples, and the island of Orleans for its plums. The wild animals are similar to those of other parts of British America. Fur-bearing animals are still trapped in the N. and N. E. portions of the province, where the Hudson Bay company has several posts. The manufactures are of considerable value, though they have not yet been extensively developed. Among the principal articles produced are flour, lumber, furniture, leather, hardware, paper, chemicals, soap, boots and shoes, cotton and woollen goods, steam engines, and agricultural implements. Ship building is carried on chiefly at Quebec. Home-made woollen and linen cloths are extensively worn by the rural population. (For statistics of agriculture, manufactures, &c., see APPENDIX to vol. xii.) The gulf of St. Lawrence abounds in fish, and the fisheries are extensively pursued on the Labrador coast, around the shores of the Gaspé peninsula, and at the Magdalen islands. The value of the fisheries for the year ending June 30, 1874, was \$1,608,660 20. The chief items of catch were cod, herring, salmon, seals, mackerel, and lobsters. The value of fish oil preserved, included in the above figures, was \$89,211 60,

viz.: cod oil, \$48,854 50; seal oil, \$27,047 50; whale oil, \$13,296; porpoise oil, \$13 60.—In respect to foreign commerce Quebec is the first province in the Dominion. The value of goods entered for consumption from foreign countries during the year 1873-'4 was \$51,980,870, including \$32,749,883 from Great Britain, \$12,703,967 from the United States, \$1,530,152 from France, \$939,451 from the West Indies, \$737,866 from Germany, \$677,017 from China, \$528,232 from Newfoundland, \$452,486 from South America, \$352,934 from Spain, \$295,958 from Japan, \$283,956 from Belgium, \$243,782 from the East Indies, \$204,581 from Holland, and \$138,712 from Switzerland. The principal articles of import were manufactures, including cottons, woollens, fancy goods, silks, iron and hardware, and machinery, besides sugar and molasses, tea, tobacco and cigars, wine, brandy and other spirits, coal, wheat, &c. The value of exports to foreign countries was \$46,393,845, of which \$36,099,441 were to Great Britain, \$5,812,596 to the United States, \$967,615 to South America, \$813,888 to Newfoundland, \$255,267 to the British West Indies, \$237,259 to France, \$229,480 to Belgium, \$169,528 to Italy, and \$169,150 to Portugal. Of the whole amount \$9,405,600 represented goods not the produce of Canada, \$901,703 coin and bullion, \$653,869 the estimated amount not returned at inland ports, and \$35,432,673 Canadian produce, viz.: of the mine, \$216,414; of the fisheries, \$778,672; of the forest, \$13,115,106; animals and their produce, \$8,189,613; agricultural products, \$11,256,057; manufactures, \$917,404; miscellaneous articles, \$162,732; new ships, \$796,675. The number of entrances from sea was 1,501, tonnage 1,135,560; clearances for sea, 1,493, tonnage 1,087,151; entrances in inland navigation from the United States, 2,793, tonnage 288,862; clearances in inland navigation for the United States, 1,487, tonnage 216,990; total entrances in the foreign trade, 4,294, tonnage 1,424,422; total clearances, 2,980, tonnage 1,304,141. The number of vessels built during the year was 63, with an aggregate tonnage of 22,189; belonging in the province at the close of 1874, 1,837 vessels, with an aggregate tonnage of 218,946. The following is a comparative statement of the foreign commerce for the six years ending June 30, 1874:

YEARS.	Imports.	Entered for consumption.	Exports.
1869.....	\$30,040,341	\$29,545,177	\$28,223,268
1870.....	32,883,916	32,166,283	37,807,463
1871.....	43,094,412	40,105,120	39,021,706
1872.....	49,376,175	47,738,687	41,228,470
1873.....	53,715,450	54,231,158	44,408,033
1874.....	51,557,072	51,980,870	46,393,845

—The province is connected with Ontario and the United States by several lines of railway, the statistics of which for 1875 are contained in the following table:

LINES.	TERMINI.	Miles in operation in the province.
Grand Trunk, W. division.....	Montreal to Detroit, Mich. (564 m.).....	45
" " E. division.....	Montreal to Trois Pistoles.....	816
" " Portland division.....	Richmond to Portland, Me. (221 m.).....	54
" " Three Rivers branch.....	Arthabaska to Doucet's Landing (opposite Three Rivers).....	85
" " Champlain division.....	St. Lambert to Rouse's Point, N. Y.....	42
" " Lachine and Province Line division.....	Montreal to Province Line.....	40
Massawippi Valley.....	Sherbrooke to Newport, Vt. (40 m.).....	34
Montreal and Vermont Junction.....	St. Johns to Burlington, Vt. (73 m.).....	26
Montreal, Chambly, and Sorel.....	St. Lambert to West Farnham.....	28
Quebec and Gosford.....	Quebec to Gosford.....	56
St. Lawrence and Industry.....	Lanoraie to Joliette.....	12
Southeastern.....	West Farnham to Newport, Vt. (65 m.).....	32
Stanstead, Shefford, and Chambly.....	St. Johns to Waterloo.....	48
Total.....		768

The Intercolonial railway is intended to be extended from Moncton, New Brunswick, N. and then W. to Rivière du Loup on the St. Lawrence. There are other lines projected or in progress. There were 19 banks on Sept. 30, 1874, with an aggregate paid-up capital of \$42,351,464.—The executive power is vested in a lieutenant governor, appointed by the governor general of the Dominion in council, assisted by an executive council of seven members (secretary and registrar and minister of public instruction, treasurer, attorney general, commissioner of crown lands, commissioner of agriculture and public works, president of legislative council, and solicitor general) appointed by himself and responsible to the assembly. The legislative authority is exercised by a legislative council of 24 members, appointed by the lieutenant governor in council for life, and a legislative assembly of 65 members (one from each electoral district), elected by the qualified voters for four years. The right of suffrage is conferred on all male British subjects 21 years old and upward who possess a small property qualification. Voting is by ballot. For judicial purposes the province is divided into 20 districts. The principal courts are the queen's bench, consisting of a chief justice and four puisné judges, and the superior court, with a chief justice and 25 puisné judges. These judges are appointed by the governor general of the Dominion in council during good behavior. The queen's bench sits four times a year at Montreal and as frequently at Quebec for the purpose of hearing appeals. Trial terms are held twice a year in different parts of the province by a single judge, in criminal cases with a jury. Three judges of the superior court sit in review of judgments of a single judge at the superior and circuit courts. Superior courts, with jurisdiction of sums exceeding \$200, are held three times a year in each judicial district by a single judge. Circuit courts, with jurisdiction of sums not exceeding \$200, are held in each county by a judge of the superior court. A vice-admiralty court is held at Quebec by a judge of vice-admiralty. Justice is administered according to the *Code civil de Québec*, which is based mainly upon the *coutume de*

Paris and the edicts and ordinances of the French kings in force at the time of the cession to Great Britain. The province is represented in the Dominion parliament by 24 senators and 65 members of the house of commons (one from each electoral district). The balance in the provincial treasury on June 30, 1873, was \$948,001 43; receipts during the following year, \$2,041,174 71, including \$1,014,712 12 subsidy from the Dominion government, \$542,140 72 from the crown lands department, \$121,540 98 from law stamps, and \$141,597 72 from licenses, &c. The expenditures amounted to \$1,992,594 88, including \$54,822 84 outstanding warrants; balance in treasury on June 30, 1874, \$1,051,404 10. The chief items of expenditure were as follows: legislation, \$173,292 98; civil government, \$146,766 41; administration of justice, \$364,555 29; police, \$63,292 20; reformatories, \$38,000; education, \$320,166 07; agriculture, \$61,852 15; immigration, \$48,978 79; colonization roads, \$114,525 76; public works and buildings, \$161,147 42; charities, \$218,224 85; crown lands department, \$128,574 82; subsidy to Southeastern railway, \$38,700.—The provincial lunatic asylum is at Beaufort, near Quebec. There are also lunatic asylums at Montreal, at St. Ferdinand d'Halifax, and at St. Johns, which receive aid from the province, the first two being under the control of the Catholics and the last of the Protestants. Aid is also granted to the Belmont Retreat inebriate asylum in Quebec, to the Catholic and Protestant deaf and dumb institutions in Montreal, to the Nazareth asylum for the blind and for destitute children in Montreal (under the control of the sisters of charity), to the reformatories at Montreal and Sherbrooke (the former Catholic and the latter Protestant), and to various hospitals and asylums conducted by religious bodies. There is a penitentiary at St. Vincent de Paul on Isle Jésus, under the control of the Dominion. The number of convicts at the close of 1873 was 122.—The public schools of the province are under the direction of the minister of public instruction, assisted by a council of 24 members (16 Catholics and 8 Protestants) appointed by the lieutenant governor. For each municipality there

are five commissioners, elected by the rate payers, having the immediate management of primary schools. In municipalities where different religious denominations exist, the minority may select syndics or trustees to direct their own schools; these are called dissentient schools. Inspectors, 32 in number, acting under the immediate direction of the minister of public instruction, are required to visit the schools of their respective districts at least twice a year and report upon their condition. The provincial grant is apportioned among the municipalities, and in each a special tax is levied. Each head of a family is also required to pay a monthly fee, varying from 5 to 40 cents, for every child between 7 and 14 years of age, whether attending school or not. Dissentient schools receive a share of these moneys. The following statistics are for 1873 :

Municipalities, number.....	852
School districts.....	8,870
School houses.....	8,831
Elementary schools.....	8,254
Pupils.....	141,990
Primary superior schools for boys.....	269
Pupils.....	21,653
Primary superior schools for girls.....	74
Pupils.....	6,930
Protestant dissentient schools.....	186
Pupils.....	6,156
Catholic dissentient schools.....	84
Pupils.....	1,509
Academies.....	83
Pupils.....	8,252
Colleges.....	87
Pupils.....	7,113
Normal schools.....	4
Pupils.....	246
Educational convents.....	129
Pupils.....	24,236
Independent schools.....	156
Pupils.....	6,261
Total educational institutions.....	4,226
" pupils.....	224,851
Male teachers.....	999
Female teachers.....	4,017
Provincial grant, amount.....	\$155,000 00
Local assessments, regular and special.....	\$456,194 40
Monthly fees.....	\$715,661 76
Total amount available.....	\$1,326,856 16
Public libraries, number.....	206
Volumes.....	108,512

Only the municipal or parochial libraries are given in the table. The schools for the training of teachers are the Laval normal school at Quebec, and the Jacques Cartier and McGill normal schools at Montreal. There are three universities: Laval university at Quebec (Roman Catholic), McGill university at Montreal (Protestant, but not denominational), and the university of Bishop's college at Lennoxville (Episcopal). The first, with its affiliated institutions in various parts of the province, is treated in the article on the city of Quebec. McGill university was founded by a bequest of the Hon. James McGill in 1811, was incorporated by royal charter in 1821, and re-organized by an amended charter in 1852. In immediate connection with it are the McGill normal and model schools and McGill college. The college has a faculty of arts, with a department of applied science, and faculties of medicine and law. The department of arts has a museum and a library of 16,330 volumes,

and the medical department a museum and a library of 4,000 volumes. St. Francis college, at Richmond, and Morrin college, at Quebec, are affiliated with the university, the former in respect of degrees in arts and the latter in arts and law. There are two affiliated theological colleges, the Congregational college of British North America, at Montreal, and the Presbyterian college of Montreal, the students in which have the privilege of pursuing the course of study in arts. The university receives a small annual grant from the province. Morrin college was founded in 1860 and incorporated in 1861. It has a faculty of divinity in connection with the church of Scotland. The university of Bishop's college was incorporated by royal charter in 1852. It comprises faculties of divinity, arts, and medicine, the last being at Montreal. Bishop's college, founded in 1843, and Bishop's college school, in 1857, are in immediate connection with it. The college has a museum and a library of 5,000 volumes. There is a medical school (*école de médecine et de chirurgie*) at Montreal affiliated with Victoria university, Cobourg, Ontario. There are 12 or 15 classical colleges besides those already named, and about the same number of industrial colleges. The number of newspapers and periodicals published in the province in 1875 was 72 (43 English and 29 French), issuing 90 editions, viz.: 14 daily, 10 tri-weekly, 3 semi-weekly, 40 weekly, 1 semi-monthly, 19 monthly, and 3 quarterly.—The following table contains the statistics of the principal religious denominations, according to the census of 1871 :

DENOMINATIONS.	Churches.	Buildings attached.	Adherents.
Baptist.....	82	44	8,686
Episcopal.....	176	908	62,449
Methodist.....	181	138	34,100
Presbyterian.....	94	154	46,165
Roman Catholic.....	610	2,097	1,019,850
Other.....	28	40	20,266
Total.....	1,071	2,831	1,191,516

Of the Baptists 3,378 were Freewill Baptists, and of the Methodists 26,737 were Wesleyans. Among denominations not named in the table were 5,240 Congregationalists, 3,150 Adventists, 1,937 Universalists, and 1,093 Unitarians. —Jacques Cartier took possession of this region in the name of the French king in 1534. The first permanent settlement was effected at the city of Quebec in 1608. Montreal was settled in 1642. The French ceded the territory, together with what is now Ontario, to Great Britain in 1763, and in 1774 the whole was organized as the province of Quebec. In 1791 it was divided into two provinces, Lower Canada and Upper Canada, and in 1841 these were reunited as the province of Canada. Upon the organization of the Dominion of Canada in 1867, they were again separated, and Lower Canada became the province of

Quebec. An elective assembly was granted to the provinces in 1791, and in 1841 responsible government was introduced. For further historical details, see CANADA, DOMINION OF.

QUEBEC, a county of the province of Quebec, Canada, on the N. bank of the St. Lawrence, including territorially, though not politically, the city of Quebec; area, 2,598 sq. m.; pop. in 1871, 19,607, of whom 14,681 were of French, 3,321 of Irish, 772 of English, and 547 of Scotch origin or descent. It is watered by the Batiscan, St. Anne, and St. Charles rivers, and other streams. Capital, Charlesbourg.

QUEBEC, a fortified city and port of entry of the Dominion of Canada, capital of the province of Quebec, situated on the N. W. bank of the river St. Lawrence, at its confluence with the St. Charles, nearly 400 m. from the gulf of St. Lawrence, and 140 m. (in a direct line) N. E. of Montreal, in lat. $46^{\circ} 49' 6''$ N., lon. $71^{\circ} 13' 45''$ W.; pop. in 1861, 59,990; in 1871,

59,699 (the decrease being attributed to the withdrawal of the British regiments forming the garrison). Of the latter number, 40,890 were of French, 12,345 of Irish, 3,974 of English, and 1,861 of Scotch origin, and 52,357 were Roman Catholics. Quebec is built on the northern extremity of an elevated tongue of land which forms the left bank of the St. Lawrence for several miles. Cape Diamond, so called from the numerous quartz crystals formerly found there, is the loftiest part of the headland, 333 ft. above the stream, and crowned with the vast fortifications of the citadel. These occupy about 40 acres, and with their outlying works obtained for Quebec the appellation of the "Gibraltar of America." From the citadel a line of wall runs westward toward the cliffs overhanging the valley of the St. Charles, and is thence continued around the brow of the promontory till it connects once more with Cape Dia-

Quebec, from Point Lévi

mond near the governor's garden. This circuit is about $2\frac{3}{4}$ m. in extent, and is pierced by five gates, now dismantled. The walls and ramparts outside of the citadel proper, though still mounted with cannon, are no longer kept in repair. The modern changes in artillery have necessitated the construction at enormous cost of a vast system of defensive works on the heights beyond Point Lévi, and others are contemplated. Cape Diamond, Durham terrace, the grand battery, and the vast balcony on the university building, on the east and north, and the ramparts between St. Louis and St. John gates, on the south and west, afford prospects rivalled by few in America. The city is divided into the upper and the lower town. The former comprises the walled city with the two suburbs of St. Louis and St. John, between the walls and the plains of Abraham. The lower town is the portion which encircles

the base of the promontory from beneath Cape Diamond to the mouth of the St. Charles, together with the suburbs of St. Roch, St. Sauveur, and Boisseauville. A very large part of the city within the walls, or the upper town proper, is taken up with the buildings and grounds of great religious corporations, the seminary and Laval university, the Ursulines and the Hôtel-Dieu, and the ancient Jesuit college, founded in 1633, and occupied as a barrack after 1812. It is now proposed (1875) to erect a building for the provincial legislature on its site. Over the remaining irregular surface, not covered by military works, are crowded the quaint mediæval streets and dwellings, built generally of stone, two or three stories high, and roofed, like the public buildings, with shining tin. Here are situated the parliament house, post office, court house, city hall, the residences of the officers of the

provincial government and of the wealthy capitalists, the principal hotels, finest stores, and chief places of amusement. The suburbs of St. Louis and St. John extend southward and westward along the plateau; the former along the foot of the citadel to that part of the

Wolfe's Monument.

plains of Abraham where Wolfe conquered, and where a modest column stands with the inscription: "Here Wolfe died victorious, Sept. 13, 1759;" the latter lower down on the slope, skirting the verge of the acclivity. A handsome iron column, surmounted by a bronze statue of Bellona, in memory of the victory of the chevalier de Lévis over Gen. Murray in 1760, was erected here in 1854, the statue being presented by Prince Napoleon Bonaparte. These suburbs, which are constantly encroaching on the historic plains, contain many beautiful private residences, and several large conventual establishments and churches.—The lower town proper was the most ancient part of Quebec, surrounding the old church of Notre Dame des Victoires on the east, built on the site of Champlain's residence, and comprising chiefly what is now the Champlain ward. It communicates with the upper town by the Champlain steps and the steep and winding Côte de la Montagne or Mountain street. Here, around Notre Dame des Victoires and the Champlain market, are the principal wharves and steamboat and ferry landings. It is the busiest and most crowded mart of the city, and a conglomeration of irregular streets. St. Peter street leads northward from this quarter to the custom house, on the very apex of the beach formed by the confluent waters. Here, beneath the guns of the grand battery 200 ft. above, are the great commercial establishments, the merchants' exchange, the banking houses, whole-

sale stores, and bonded warehouses. St. Paul's street connects with St. Peter's before the custom house, and stretches westward on the narrow strand between the cliff and the bay, amid breweries, distilleries, manufactories, and gas works, till it meets, near the mouth of the St. Charles, St. Joseph street, the main artery of the large suburb St. Roch. On the banks of the St. Charles are the principal ship yards. St. Roch and Boisseauville are the home of the laboring classes. The chief institutions here are the large convent and schools of the sisters of Notre Dame near the church of St. Roch, and the general hospital on the banks of the St. Charles.—From Près-de-ville, at the foot of Cape Diamond, proceeding S. W. as far as Sillery, the shore of the St. Lawrence is indented with 17 coves, all filled with lumber rafts. The opposite shore of the St. Lawrence, from New Liverpool to and beyond Point Lévi, presents a scene of activity scarcely surpassed by the city itself. New Liverpool is connected with Quebec by a steam ferry, has several factories and mills, a large trade in lumber, and the church of St. Romuald, the finest on the lower St. Lawrence. Adjoining New Liverpool is South Quebec, with a population of 3,000 (increasing rapidly), and immense lumber yards from which large yearly shipments are made. It is the stopping place of the transatlantic steamers from Liverpool. St. Joseph, between South Quebec and Lévis, has as large a business as the former. The town of Lévis or Point Lévi, situated on the right bank opposite the island of Orleans, just where the main branch of the St. Lawrence turns eastward, is the terminus of the Grand Trunk railway and of the Lévis and Kennebec railway. It has several churches, a thriving college, a succursal of the seminary of Quebec, a convent with a large female academy, several other flourishing schools, hotels, telegraph offices, extensive lumber and ship yards, and a considerable trade.—Quebec has many fine buildings. The custom house, on the bank of the river, is an imposing Doric edifice with a dome and a façade of noble columns, approached by a long flight of steps. Of the church edifices, the cathedral of Notre Dame is the most remarkable. It was elevated in October, 1874, to the rank of a basilica, on the occasion of the second centenary of the erection of the see of Quebec. It is a plain edifice externally, with a cut stone front added to it in 1844, and unpleasantly contrasting with the remainder of the structure. It is 216 ft. long, 180 wide, and about 80 in interior elevation, capable of seating 4,000 persons, with a spacious sanctuary, a richly decorated high altar, and several original paintings of great value. The Protestant cathedral, a plain gray edifice surmounted by a tall spire, stands in the centre of a large square, enclosed with an iron fence. S. E. of it is the parade ground, a central point, adorned with a fine fountain. The garden of the fortress, another fine pro-

menade, has an obelisk erected in 1828 to the memory of Wolfe and Montcalm. The Chalmers church, the Wesleyan church (in the flamboyant style), and the chapel of the gray sisters are good specimens of Gothic church architecture. The marine hospital, built after the model of the temple of the Muses on the banks of the Ilissus, the archbishop's palace, the parliament buildings, the theatre, the city hall, and the university buildings are worthy of notice.—The St. Lawrence is about three quarters of a mile (1,314 yards) wide opposite Cape Diamond, but the mouth of the St. Charles forms with it a magnificent basin nearly 4 m. long and 3 m. wide. The beautiful island of Orleans and the shores of Point Levi shut in this basin on the northeast and east. The depth of the water is about 28 fathoms. The ordinary tide is 17 or 18 ft. at new and full moon; but the spring tides attain a height of 23 or 24 ft. The harbor is safe and commodious, and the largest vessels can lie at the wharves. In the latter part of December the river is closed by ice, and navigation ceases till the latter part of April, when the ice usually disappears very suddenly. There are two regular lines of transatlantic steamers, running weekly between Quebec, Liverpool, and Glasgow, and one fortnightly line between Quebec and London. There are also weekly steamers for the gulf ports, steamers for the Saguenay almost daily in the summer months, and semi-weekly for the stations intermediate between Quebec and Three Rivers, besides several ferries.—Quebec, next to Montreal, is the most important centre of maritime commerce in British North America. It is one of the largest lumber and timber markets on the American continent. The principal imports are woollen, cotton, and silk goods, iron, hardware, coal, and salt. The exports consist chiefly of ships, lumber, and grain. The ships built at Quebec are renowned for their beauty, solidity, and sailing qualities. Much the larger portion of the commerce is with Great Britain. The value of imports in 1860 was \$3,358,676; of exports, \$7,271,959. The value of imports and exports for the four years ending June 30, 1874, was as follows:

YEARS.	Imports.	Exports.
1871.....	\$6,277,370	\$12,688,904
1872.....	7,582,221	11,931,077
1873.....	6,546,976	12,587,276
1874.....	7,422,063	12,746,305

The number of entrances during the last named year was 983, tonnage 790,361, of which 533, tonnage 381,032, were in ballast; of clearances, 846, tonnage 671,386; number of vessels built, 52, tonnage 21,065. The number of vessels belonging to the port on June 1, 1874, was 801, with an aggregate tonnage of 100,564. According to the census of 1871, the amount of capital invested in manufactures was \$2,870,638; number of hands employed, 7,250; amount

of yearly wages, \$1,459,279; value of raw materials, \$4,771,459; total value of products, \$8,449,752. The principal articles of manufacture are boots and shoes, saw-mill products, ships, bakery products, furniture, foundry products and machinery, refined sugar, India-rubber goods, rope and twine, clothing, cooperage, carriages, ale and beer, furs and hats, sash, doors, and blinds, soap and candles, and tobacco. There are three banks with an aggregate paid-up capital on Sept. 30, 1874, of \$6,807,205; circulation, \$3,044,719; deposits, \$8,614,438; specie and Dominion notes, \$1,623,750; discount, \$14,603,747.—Quebec returns three members to the Dominion house of commons, and three to the provincial legislature. It is divided into eight wards, and is governed by a mayor, eight aldermen, and 18 councillors. It is the seat of a Protestant bishop and a Roman Catholic archbishop, and has 19 churches and a synagogue. The chief benevolent institutions are: the Hôtel-Dieu, with its convent and hospital, founded in 1639 by the duchess d'Aiguillon, and in 1875 comprising 45 sisters of the Sacred Blood of Dieppe, 80 beds for patients of every creed and nationality, and ministering gratuitously to 10,000 patients yearly; the general hospital, with convent and halls for incurable patients, founded at a personal expense of 100,000 crowns by Bishop de Saint-Valier in 1693; the hospital of the Sacred Heart of Jesus, a branch of the general hospital, opened Sept. 8, 1873; the convent of the sisters of charity, or gray sisters, founded in 1848 by Archbishop Turgeon, combining an asylum for the aged and infirm poor, an orphanage, and a free industrial school for 1,000 pupils, the whole supported by private industry and charity; the house of the Good Shepherd, a reformatory for the fallen, a conservatory for exposed girls, and a school for 500 pupils, established in 1850, supported during the first year by the guild of St. Vincent de Paul, and at present almost entirely self-supporting with the aid of private charity. Connected with the medical school of the Laval university are the maternity hospital and the dispensary, the former founded in 1852 by the Rev. Joseph Auclair, aided by Mlle. Méthivier, a poor seamstress (who has also opened a private lying-in asylum, now governed by herself); the latter established in February, 1866, also by Father Auclair and the seminary of Quebec, and exclusively supported by them with the aid of private charity, and a grant of \$500 from the legislature toward the hospital. Both afford assistance to all applicants without exception. The maternity hospital is under the charge of the sisters of the Good Shepherd, and the dispensary under that of the sisters of charity. There are also the St. Bridget's asylum, connected with St. Patrick's Roman Catholic church, and the ladies' Protestant home, the latter providing for old men and young unprotected girls. The marine hospital, on the bank of the St. Charles, near the general hospital,

and the Canada military asylum for the widows and orphans of British soldiers, are maintained at the public expense.—The most important educational institution is the "Seminary of Quebec," with its offshoot and dependent the Laval university. The seminary was founded in 1663 by François de Montmorency-Laval, first bishop of Quebec, who bestowed upon it at his death in 1708 all the personal property in Canada which he had purchased by the sale of his patrimonial estates in France. The *grand séminaire* or theological school was opened in 1666, and the *petit séminaire* or collegiate school in 1668. The first building for the special use of these schools, of stone, on the site of the present middle seminary building, was erected in 1678; it was burned in 1701, rebuilt, and again burned in 1705, when it was built larger. It was originally designed only for clerical students; but when the Jesuit college, founded in 1637, was closed after the conquest, the seminary courses were thrown open to all classes. The whole community of professors and pupils numbered 54 persons in 1704, and 110 in 1800. Within the present century two new wings have been added to the original building, each far exceeding it in size and costliness. The institution was raised to the rank of a university by a charter signed by Queen Victoria Dec. 8, 1852, the power of conferring the canonical degrees in theology being granted by Pius IX., March 6, 1853. The corner stone of the principal university building was laid Sept. 20, 1854. The three buildings erected are 576 ft. long (the main building being 286 ft.), five stories high, and of cut stone; the whole has been completed at a cost of \$238,787, without counting the sums expended for museums, library, apparatus, and picture gallery, amounting to about \$500,000. In 1865 the whole of the new wing of the theological seminary and a portion of the old were burned down; but the directors rebuilt and enlarged these portions, giving a total length of 684 ft. for the seminary buildings alone. The buildings connected with the main university edifice are a separate school of medicine and a boarders' hall for students in law and medicine. In thus founding the university and providing it with all that was needful, the directors declined all aid from the government or the city. The large hall of convocation has seats for 1,200 persons, besides galleries for ladies; the chemical laboratory is spacious, fire-proof, and provided with complete apparatus. The mineralogical and geological collections were first prepared under the direction of the Rev. John Holmes, and afterward, with several large subsequent additions, arranged systematically by Prof. T. Sterry Hunt. The museum of botany is equally complete. That of zoölogy contains upward of 1,300 different birds and over 7,000 insects. The ethnological collection is chiefly made up of the remains of Canadian Indians, and is mainly due to the labors of Dr. J. C. Taché. The museum of the medical de-

partment is especially complete. The gallery of paintings, lately thrown open to the public, contains 150 originals, duplicates, and copies, sent from France after the revolution of 1791, and repurchased from various owners in Canada, by the Hon. Joseph Légaré. The university library contains upward of 55,000 volumes, independently of the libraries belonging to the theological and preparatory departments, amounting to about 20,000 volumes more. The nine directors of the seminary are by right members of the university council, the superior of the seminary being *ex officio* rector of the university. The other members of the council are the three senior professors in each of the faculties of divinity, law, medicine, and arts. The Roman Catholic archbishop of Quebec is *ex officio* visitor of the university; to him belongs the appointment of the professors of divinity and canon law, and the conferring of all degrees in the same. In 1875 there were five titular professors in divinity and its kindred sciences, six in law, nine in medicine, and five titular and six associate professors in arts, and one honorary professor and three tutors or professors *chargés de cours*. The divinity course embraces four years, the law course three years, and the medical course four years. There are six affiliated colleges: the college or preparatory seminary of Quebec, the college of Nicolet, the college of Ste. Anne de la Pocatière, the college of Ste. Thérèse de Blainville, the college of St. Joseph, Three Rivers, and that of St. Germain, Rimouski. The affiliated theological seminaries are those of Quebec, Ste. Anne de la Pocatière, and St. Germain de Rimouski. About 40 priests and theological students are employed in various capacities: of these the board of directors, or the corporation of the seminary, receive no salary, being provided with all necessities at an annual expense of about \$250 for each. The auxiliary priests receive, besides their board, a salary of \$100; the tutors or disciplinarians who are theological students have each a yearly salary of \$55; and the whole amount of salaries is considerably less than \$2,000. In 1874 there were in all 290 university students, of whom 55 were in the divinity school, 36 in the law school, 93 in the medical school, and 106 in the junior and senior classes of philosophy.—Besides the university, Quebec has the Laval normal and model school, founded in January, 1857, under the superintendence of the Hon. Pierre J. O. Chauveau; the Morrin college, the only non-episcopal Protestant one in the province; and the Quebec high school. Morrin college occupies the old prison in the centre of the upper town; it has 10 professors, but is inadequately patronized. The high school has been always very successful, and has 200 students, with a large staff of professors and a handsome library. The other principal schools are: the Ursuline convent, founded in 1639, having in 1875 89 nuns, and educating 260 boarders, 140

half boarders, and 400 day scholars, together with 55 pupil teachers and 200 pupils belonging to the female department of the Laval normal school; the congregation of Notre Dame, with their chief convent and school near St. Roch's church, established in 1843 by the Rev. Z. Charest, and having two schools in the city with 2,100 pupils in 1875, most of whom are educated without cost to the parents; and the "Brothers of the Christian Schools," founded in 1842 by the late Archbishop Baillargeon, with three residences and six schools and a commercial academy founded by the Rev. Joseph Auclair, educating gratuitously 2,500 pupils, and receiving in return the bare necessities of life from the free bounty of the citizens. There are several flourishing literary societies, foremost among which is the Quebec literary and historical society, the oldest chartered institution of the kind in Canada, founded in 1824. It still has a valuable library, though a great portion of its most precious books and manuscripts were destroyed with the parliament buildings in 1854. The Canadian institute, the entomological society, and the St. Patrick's literary institute possess valuable libraries, as well as the society of advocates, the board of trade, and the merchants' exchange. There are five daily newspapers (three of which are in the French language), one tri-weekly, four weekly, and three monthly periodicals.—The site of Quebec was visited by Cartier in 1534-'5, and the city was founded by Champlain in 1608. It was taken by the English in 1629, and restored to France by the treaty of 1632. In 1636 it had 100 inhabitants. It was the colony of a concessionary company, who did not fulfil their promises to the settlers, and hence its growth was slow. The magistrate, named by the company, was called a syndic, and had powers similar to those of a mayor. The king, dissatisfied with the management of the company, took the colony into his own hands, and in 1663 appointed a governor and created the sovereign council of Quebec, who were charged with its government. In 1690 the neighboring English colonies made an unsuccessful maritime expedition against it. In 1711 the attempt was renewed, with no better success. The first attempt at erecting stone fortifications was made after the first of these attacks, the place having been previously protected only by palisades. In 1734 it had, including its suburbs, only 4,603 inhabitants. In 1759, during the seven years' war, the English Gen. James Wolfe attacked the city and bombarded it. On Sept. 13 took place the first battle of the plains of Abraham, in which both the contending generals fell, and England gained at one blow an American empire. On Sept. 18 Quebec capitulated after a siege of 69 days. The French attempted its recapture, and in the following spring the second battle of the plains of Abraham was fought, and victory sided with the French colonists; but at the treaty of peace in 1763

Louis XV. ceded the whole of New France to the English. Quebec, ruined by Wolfe's bombardment, rose slowly from its ashes, though its commerce increased. In 1764 the first newspaper, the "Quebec Gazette," published in two languages, made its appearance. In 1775 the city had only 5,000 inhabitants. In December, 1775, a small American force under Gen. Montgomery attempted its capture, but failed, with the loss of about 700 men and their commander (Dec. 31). In 1792, the year after the inauguration of the representative system in Canada, the first Lower Canadian parliament was convoked at Quebec, and the city remained the seat of government for the lower province till the union of the Canadas in 1841. During this period its growth was steady and moderately rapid; in 1844 its population was 32,876, besides 2,797 in the suburbs. Two terrible fires occurred in 1845, at a month's interval, in the faubourgs of St. Roch and St. John; nearly 3,000 houses were burned, and property to the amount of more than \$8,000,000 was destroyed. Large conflagrations also occurred in 1862 and 1866; and great improvements have since been made in the fire department and a more secure style of building adopted. In 1851 Quebec again became the capital for four years under the arrangement for alternating capitals adopted in 1849, and kept up till 1858, when Ottawa became the seat of government. After the erection of the Dominion of Canada in 1867, Quebec became the capital of the province of Quebec.

QUEDLINBURG, a town of Prussia, in the province of Saxony, beautifully situated near the lower Hartz mountains, on the Bode, a tributary of the Saale, 31 m. S. W. of Magdeburg; pop. in 1871, 16,402. Two arms of the Bode divide the old from the new town, and there are four suburbs, one laid out in 1862. The castle, on a rocky eminence, once the residence of the local abbesses, is in decay, and is partly used as a school. The Schlosskirche, with remarkable art treasures, was made in 1838 the theme of a special work by Ranke and Kugler. There are seven Protestant churches, and one Catholic. A gymnasium was established here by Luther and Melancthon. The ruined convent of St. Wipertus is now a barn. In the Brühl garden are monuments of Klopstock and Carl Ritter, who were born here. Quedlinburg is a market for seeds, agricultural and garden products, cattle, books, and woollen goods. The see of Quedlinburg was celebrated from the 10th to the 18th century for its abbesses, who had a seat in the diet as princesses of the German empire. The first abbess was Matilda, daughter of Otho I. (968-999). In 1539 the abbesses joined the reformation. Conspicuous among those of the 18th century were Anne Amalia, a sister of Frederick the Great, and Sophia Albertina, a daughter of King Adolphus Frederick of Sweden, who was the last, retiring in 1802, but retaining the title till her death.

QUEEN (Goth. *queins*, *quens*, a woman, a wife; Icelandic, *krán*; A. S. *cwén*, wife, queen; Gr. *γυνή*, a woman), the wife of a king, or a woman who is the sovereign of a kingdom. In the former capacity she is regarded in most countries as a person of dignity only inferior to that of her husband, and possesses all the privileges enjoyed by a *feme sole*. Thus in England she can receive grants from or make them to her husband, can purchase or convey land without his concurrence, can sue and be sued alone, and dispose of her property by will. She has a separate household and separate courts and officers, is exempted from paying tolls and amercements, and has other extraordinary privileges; and to compass or imagine her death, or to violate or defile her person, even with her consent, is treason. If accused of treason herself, she is tried by the peers of parliament. She is also entitled to be crowned with full regal solemnities. In other respects she is on a footing of equality with the subjects of her husband, in accordance with the maxim of the Roman law: *Augusta legibus soluta non est*. As a sovereign princess, a signification not originally comprehended in the term queen, she possesses all the attributes of a king; and her husband, if she is married, is her subject. In France, where by the Salic law a female could not succeed to the throne, the mother of a sovereign sometimes exercised royal authority during the minority of her son, in which case she was called the queen regent. The queen dowager is the widow of a king, and as such enjoys most of the privileges accorded to her during the lifetime of her husband. In England she does not lose her rank, although she marry with a commoner; but no one can contract a marriage with her without a special license from the sovereign. When the queen dowager is mother of the sovereign, she is commonly called the queen mother.

QUEEN ANNE, an E. county of Maryland, bordered E. by Delaware, W. by Chesapeake bay, and N. W. by Chester river, and drained by several creeks; area, 400 sq. m.; pop. in 1870, 16,171, of whom 6,592 were colored. It has a rolling surface and fertile soil. The chief productions in 1870 were 326,828 bushels of wheat, 605,975 of Indian corn, 59,167 of oats, 26,845 of Irish and 9,467 of sweet potatoes, 22,581 lbs. of wool, and 107,422 of butter. There were 3,703 horses, 586 mules and asses, 3,121 milch cows, 1,201 working oxen, 3,050 other cattle, 5,373 sheep, and 9,942 swine; 1 fruit-canning establishment, 1 woollen mill, and 3 saw mills. Capital, Centreville.

QUEEN CHARLOTTE ISLANDS, a group in the N. Pacific ocean, about 130 m. N. W. of Vancouver island, and about 80 m. from the coast of British Columbia, to which they belong. They consist of four principal islands, with numerous adjacent islets, extending N. N. W. and S. S. E. about 180 m., and separated by narrow channels; aggregate area about 5,000

sq. m. The largest islands are Prevost at the southern extremity of the group, Moresby, Graham, and North at the northern. Moresby island is about 80 m. long and from 10 to 30 m. wide, with an area of 1,500 sq. m. Graham island is about 80 m. long and from 20 to 60 m. wide, with an area of 3,000 sq. m. Prevost and North islands are much smaller. The surface is hilly, but not mountainous. The interior is clothed with magnificent forests of pine, cedar, and similar trees. Copper and iron ores and anthracite coal have been found. Various kinds of berries are abundant, and potatoes are cultivated by the natives. There is thought to be much arable land. The climate is equable, the winters being mild and the summers cool. The harbors are numerous. The surrounding waters swarm with fish. The natives, divided into several tribes, number 4,000 or 5,000.

QUEEN CHARLOTTE SOUND. See VANCOUVER ISLAND.

QUEENS, a S. E. county of New York, in the W. part of Long Island, bordered N. by Long Island sound and S. by the Atlantic ocean; area, 410 sq. m.; pop. in 1870, 73,803. Its surface is somewhat hilly; much of the soil is fertile, and nearly all is highly cultivated. The shores are much indented by bays and inlets, and on the S. beach are many small islands. It is intersected by the Long Island and several other railroads. The chief productions in 1870 were 83,258 bushels of wheat, 58,576 of rye, 535,796 of Indian corn, 164,599 of oats, 7,063 of barley, 24,685 of buckwheat, 49,145 of peas and beans, 734,549 of potatoes, 48,325 tons of hay, 11,254 lbs. of wool, and 362,250 of butter. There were 7,733 horses, 8,627 milch cows, 569 working oxen, 2,294 other cattle, 3,838 sheep, and 8,229 swine; 4 manufactories of brick, 28 of carriages and wagons, 7 of cordage and twine, two of explosives and fire-works, 1 of fertilizers, 1 of India-rubber and elastic goods, 3 of liquors, 4 of machinery, 8 of brick and stone, 4 of oil, 5 of paper, 11 of saddlery and harness, 4 of sash, doors, and blinds, 2 of starch, 3 of stone and earthen ware, 14 of tin, copper, and sheet-iron, 4 flour mills, 5 lumber mills, and 4 ship yards. The court house is in the town of North Hempstead, about a mile from Mineola station on the Long Island railroad. The county clerk's office is in the village of Jamaica. A new court house is in course of erection in Long Island City.

QUEEN'S. I. A S. central county of New Brunswick, Canada, intersected by the St. John river; area, 1,480 sq. m.; pop. in 1871, 13,847, of whom 5,469 were of Irish, 4,842 of English, 2,142 of Scotch, and 918 of Dutch origin or descent. Around Grand lake considerable quantities of bituminous coal are mined. The county is traversed by the European and North American railway. Capital, Gaagetown.

II. A S. W. county of Nova Scotia, Canada, bordering on the Atlantic ocean; area, 1,065 sq. m.; pop. in 1871, 10,554, of whom 5,270

were of English, 2,245 of German, 1,150 of Scotch, and 1,110 of Irish origin or descent. The coast is deeply indented, and bordered by a rugged ridge extending many miles inland. The interior is beautifully diversified with valleys, rivers, and lakes. The soil along the streams is fertile. Capital, Liverpool. **III.** The central county of Prince Edward Island, Canada; area, 771 sq. m.; pop. in 1871, 42,651. It is traversed by the Prince Edward Island railway. The surface is diversified and the soil fertile. Capital, Charlottetown, which is also the capital of the province.

QUEEN'S, a S. E. county of Ireland, in the province of Leinster; area, 664 sq. m.; pop. in 1871, 77,071. The Slieve-Bloom mountains divide it from King's county. The principal rivers are the Barrow and its tributary the Nore. Lough Annagh, on the N. boundary, the only lake of any importance, is not more than a mile long. Iron and copper ore and potter's clay are found; and anthracite coal mines are worked. Excepting in the centre of the county, where there are extensive bogs, the soil is generally fertile. The principal towns are Mountmellick, Mountrath, and Maryborough.

QUEENSLAND, a British colony in Australia, comprising the N. E. part of the island, lying between lat. 10° 43' and 29° S., and lon. 138° and 153° E., bounded N. by Torres strait, N. E. by the Coral sea, E. by the South Pacific, S. by New South Wales and South Australia, W. by South Australia and the Northern Territory, and N. W. by the gulf of Carpentaria; area, including the coast islands, 678,000 sq. m.; pop. in 1871 (revised), 120,104; in 1873, estimated at 146,690. Of the population in 1871, 71,767 were males and 48,337 females; 47,343 were born in Australia and New Zealand, 26,296 in England and Wales, 8,564 in Scotland, 20,972 in Ireland, 8,317 in Germany, 3,305 in China, 215 in the United States, and 188 in France. The religious division of the inhabitants in 1871 was as follows: Anglicans, 43,764; Roman Catholics, 31,822; Presbyterians, 15,373; Wesleyans, 7,206; Congregationalists, 2,647; other Protestant denominations, 11,485; Jews, 291. No trustworthy information can be obtained concerning the number of aborigines.—The coast line, from Point Danger, the S. E. extremity, to Cape York, the most northerly point, has a general N. W. direction; it runs thence nearly due S. to the southernmost part of the gulf of Carpentaria, forming the York peninsula, when it turns W. and then nearly N. W. to the boundary line of the Northern Territory. Its entire length is about 2,500 m. Off the E. coast, at an average distance of 20 to 30 m. from the shore, though in some places 60 m., lies the coral reef called the Great Barrier, which extends from Cape York to lat. 24°, about 1,250 m. Within this reef, through which there are frequent though dangerous passages, is a navigable sea, with an ordinary depth of 10 to 25 fathoms;

but at the S. end, where the channel is widest, the depth exceeds 60 fathoms. The coast, both within this sea and S. of it, is indented by numerous fine bays, with capacious natural harbors, many of which form the outlets of navigable rivers. The principal of these are Moreton bay, at the head of which stands Brisbane, the capital of the colony, Hervey bay, Port Curtis, Keppel bay, Port Bowen, Port Denison, and Halifax, Rockingham, Trinity, Princess Charlotte, Weymouth, and Shelburne bays. The whole E. coast is strewn with islands, chiefly small. The largest, Frazer or Great Sandy island, in lat. 25°, is about 80 m. long by 20 m. wide. In Torres strait are Mulgrave's, Banks, and Prince of Wales islands, and in Carpentaria bay is a group called the Wellesley islands, the largest of which is Mornington. Along the gulf of Carpentaria the coast is low and sandy, with the exception of the S. part, where mountain ranges approach the sea. The E. coast is generally mountainous. From 50 to 100 m. from the shore, and parallel to it, is a mountain chain forming several distinct ranges, from which numerous spurs run to the sea. The principal of these are the Gilbert range in the north, the Expedition range in the middle, and the Denham range in the south. The general height of the mountains is not more than 2,000 ft., but some of the peaks are much higher. Mt. Mitchell, S. of Brisbane, is 4,120 ft. high; Mt. Eliot, near Halifax bay, 4,122 ft.; and two of the peaks of the Bellen-den Kerr range, on the coast S. of Trinity bay, are respectively 5,158 ft. and 5,438 ft. high. Beyond the mountains, table lands covered with herbage and well supplied with water, but without trees, stretch across the country to the gulf of Carpentaria, broken occasionally by mountain ranges. Within certain distances of the principal mountains the rains fall regularly, and the plains are covered with light timber. The mountains themselves are heavily wooded. Queensland is drained by many rivers, several of which are navigable. In the S. part most of the streams flow into New South Wales. The chief rivers that find an outlet on the E. coast are the Brisbane, which, together with the Arrowsmith, Logan, Pine, and Caboolture, empties into Moreton bay, and it is navigable for 75 m. by steamers; the Mary and the Burnett, which flow into Hervey bay; the Fitzroy, which, with its affluents, the Dawson, Mackenzie, and Isaacs, drains several hundred miles of country, and is navigable for 60 m. above its mouth in Keppel bay; and the Burdekin, which is fed by the Bowen, Belyando, and others, and empties into Wickham bay. The Mitchell, Van Diemen, Flinders, and Albert flow into Carpentaria bay. The banks of the rivers are usually high and well wooded, being mostly covered with thick hedges of mangroves and forests of fig trees and eucalypti, festooned with flowering vines. On the mountains the pine and cedar, and many varieties of trees unknown elsewhere, grow luxu-

riantly.—The climate of Queensland is preferable to that of other parts of Australia, it being said to resemble closely that of Madeira, and the colony has been for many years the resort of invalids from the other settlements. The summer is hot, the thermometer sometimes indicating 100° in the shade; but the atmosphere is dry, and the heat is so tempered by the sea breezes that the nights are always cool. It is generally exempt from the hot winds which prevail in other parts of Australia. Rain falls regularly in the hot season, but a dry season is experienced every six or seven years. Most of the productions of both temperate and tropical countries can be cultivated with success. There are few indigenous fruits or vegetables, but those of almost all other countries have been naturalized. The soil is well adapted for the cultivation of cotton, sugar cane, and tobacco, as well as of maize, wheat, and other cereals, and all the vegetables and flowers of northern Europe. At the end of 1872 there were 62,491 acres under cultivation, of which 12,002 were devoted to cotton and 11,757 to sugar cane. The orange, lemon, citron, pineapple, fig, banana, peach, nectarine, grape, guava, mulberry, apple, pear, granadilla, and many other fruits, grow to perfection. In consequence of the high price of labor and the difficulty of finding a market for agricultural products, the greater part of the industry is devoted to stock raising. The downs furnish rich pasturage, and sheep and cattle increase rapidly. Horses are so numerous that only the best bred animals are selected for breaking. Cattle and sheep are frequently boiled down for their tallow and hides, but attempts have been made of late years to preserve the meat for exportation to Europe. The staple product is wool, the quality of which increases in fineness as the flocks are driven northward. About 195,000 sq. m. are occupied for sheep raising. At the close of 1872 the live stock in the colony numbered 6,687,907 sheep, 1,200,992 horned cattle, 92,798 horses, and 35,732 swine.—Queensland is rich in minerals, principally gold, copper, and coal. Gold was first discovered at Canoona, about 35 m. from Rockhampton. In 1867 several other fields were opened, the richest of which was at Gympie creek, 130 m. from Brisbane, which proved to be very rich in gold-bearing quartz. There are now more than a dozen gold fields in the colony, mostly in the N. and N. W. districts. The total gold product for 1872 was 178,308 oz., valued at £592,993. The richest copper mines are at Clermont, and the chief coal mines are on the Brisbane and Bremer rivers. The product of the coal mines for 1872 was 27,727 tons, valued at £16,120.—Queensland is divided into 12 districts: Moreton, Darling Downs, Burnett, Port Curtis, Maranoa, Leichhardt, Kennedy, Mitchell, Warrego, Gregory, Burke, and Cook. The principal towns, besides Brisbane, are Ipswich, Rockhampton, Gympie, Maryborough, and Toowoomba. The government is vested in a gov-

ernor appointed by the crown, an executive council, and a parliament of two houses, the legislative council and the legislative assembly. The governor is commander-in-chief of the troops, and has also the title of vice admiral. The executive council consists of a colonial secretary, treasurer, postmaster general, attorney general, minister for lands, and minister for mines and public works. The legislative council consists of 21 members, nominated by the crown for life. The house of assembly comprises 32 deputies, elected by ballot for five years. Electors must be natural born or naturalized citizens, 21 years of age, who possess certain small property qualifications, and have suffered no condemnation for criminal acts. Justice is administered through a chief justice, a puisné judge, each of whom has associates, and several district judges. There is no state church, an act having been passed in 1860 abolishing state aid to religion. Nearly all the leading denominations are represented in the colony, and all have numerous places of worship. Education is under the control of a board of education, consisting of six members appointed by the government, with one of the ministry for chairman. It is similar to the national system in vogue in Ireland, and is entirely free. Aid is granted to schools not established by the board, which are called non-vested schools, on their complying with certain regulations. The state also assists schools more advanced than primary schools. In 1870 there were 111 public schools, 226 teachers, and an aggregate attendance of 16,227. Of these, 89 were primary schools, with 170 teachers and 11,087 scholars. Brisbane, Ipswich, and Maryborough have grammar schools. There were also 101 private schools in the colony in 1870. The gross revenue in 1873 was £1,120,034, and the expenditure £948,750. The public debt on Dec. 31, 1872, was £4,547,850. The total value of the imports in 1873 was £2,881,726; exports, £3,542,513. Commercial intercourse is chiefly with the other Australian colonies and with Great Britain. In 1873 the imports from Great Britain amounted to £815,638, and the exports to it to £871,235, of which £534,935 was for wool. The principal articles exported were wool, tallow, gold, copper, tin ore, cotton, live stock, hides, timber, and provisions. The total export of wool in 1872 was 17,793,000 lbs. The entrances at the various ports in 1870 were 476 vessels of the aggregate capacity of 139,292 tons. In the same year 2,825 immigrants were landed. At the close of 1873 there were 218 m. of railway in operation. The chief lines are the Southern and Western, from Ipswich to Warwick, 176 m.; and the Northern, from Rockhampton in the direction of the Dawson river, which in 1873 was completed to Westwood, 30 m. The railways have a gauge of 3 ft. 6 in. At the close of 1872 there were 3,368 m. of telegraph wire in operation, with 53 stations. (For information relating to the geology, zoölogy, botany, and aborigines, see

AUSTRALIA.)—The E. coast of Queensland was discovered by Capt. James Cook, who anchored in Moreton bay in 1770. The country was at first attached to New South Wales, under the name of the Moreton Bay district. In 1823 the Brisbane river was explored by Oxley, the surveyor general of New South Wales, and the site of the city of Brisbane selected for a penal station. In 1825 the first convicts were landed there, and employed in making roads and other public improvements. Convict immigration ceased in 1839, and in 1842 the country was thrown open to free settlers. In 1859, in deference to repeated petitions from the settlers, it was erected into an independent colony.

QUEENSTOWN, a town of county Cork, Ireland, on the S. side of Great island, in the harbor and 7 m. E. S. E. of the city of Cork; pop. in 1871, 10,039. It is built on a steep acclivity, the streets rising one above another parallel to the beach, and the piers forming a fine promenade. A splendid Catholic cathedral is in course of erection (1875). The harbor is 3 m. long by 2 m. broad, with an entrance 2 m. long and 1 m. wide. It contains Spike island with Fort Westmoreland, artillery barracks, and a prison for 800 convicts, who are employed in the fortifications and in constructing a dockyard and basin on the adjoining island of Haulbowline. This island contains a depot for ordnance and victualling stores, and near it is Rocky island, with barracks and powder magazines cut out of the rock. Queenstown is the station of the commanding admiral, of the royal yacht club, and of transatlantic steamers. A vast number of Irish emigrants embark here for the United States, and many passengers land here in preference to Liverpool. Previous to the wars with Napoleon I. it was a small village of fishermen; it then became important as a naval station. It was known as the Cove of Cork until 1849, when the name was changed on occasion of Queen Victoria's visit.

QUEKETT, John Thomas, an English microscopist, born at Langport, Somersetshire, in 1815, died at Pangbourne, Berkshire, Aug. 20, 1861. He entered London hospital as a student in 1831, and became a licentiate of the apothecaries' company and member of the royal college of surgeons. The latter body having established a studentship of human and comparative anatomy, he was unanimously elected to it, and in 1843 was appointed assistant conservator of the Hunterian museum, and on Professor Owen's retirement in 1856 conservator of the museum and professor of histology. He was chosen a fellow of the royal society in 1860. He published "Practical Treatise on the Use of the Microscope" (8vo, 1848; new ed., 1865); "Lectures on Histology" (2 vols. 8vo, 1852-'4); and an "Illustrated Catalogue of Specimens in the College Museum in Lincoln's Inn Fields."

QUELPAERT ISLAND (called by the Japanese Kandozan), an island in the Eastern sea, about

55 m. S. of Corea, and 110 m. W. N. W. of the Goto islands. It is about 45 m. long and 20 m. broad. The soil is volcanic and fertile, good timber abounds, and grazing pastures are extensive. The highest peak reaches an altitude of 6,500 ft. The population is considerable; villages, each under the control of a chief, being numerous. There are no harbors. Corea claims this island, and uses it as a place for exiles and criminals.

QUÉRARD, Joseph Marie, a French bibliographer, born in Rennes, Dec. 25, 1797, died in Paris, Dec. 3, 1865. He was early connected with the publishing business, and from 1819 to 1824 with an establishment in Vienna. He afterward published in Paris *La France littéraire* (10 vols., 1827-'42), followed by *La littérature française contemporaine* (6 vols., 1842-'57), which was prepared by others from the middle of the second volume, owing to his difficulties with the publisher and to his forfeiture of the copyright. Among his other compilations are *Les auteurs déguisés de la littérature française au 19^e siècle* (1845), and *Les supercheries littéraires dévoilées* (5 vols., 1845-'56).

QUERCITRON, a dyestuff, the bark of the black oak, *quercus coccinea*, var. *tinctoria* (*Q. tinctoria* of authors), in some localities called the yellow-barked oak. (See OAK.) The black outer portion of the bark being removed, the inner portion is found to contain a coloring principle which stains the saliva yellow when the bark is chewed; this is extracted by boiling water, giving to it a brownish yellow color, which is deepened by alkalies and brightened by acids. The bark is largely employed in the United States as a dye, and it is also reduced to a coarse powder and shipped to Europe in great quantities for the same use, particularly in calico printing. When this decoction has been deprived of tannin by means of glue, a fine yellow color is obtained upon fabrics mordanted with alum, and various shades of olive with iron mordants. The coloring principle is called quercitrine, or from its acid reaction quercitric acid. Black-oak bark is used for tanning also, but its yellow color makes it objectionable. Its astringent and tonic properties have led to its use in medicine, but white-oak bark, having similar medical properties without the color, is preferred.

QUERÉTARO. I. A central state of Mexico, bounded N. by San Luis Potosí, E. by Hidalgo, S. by Mexico, S. W. by Michoacan, and W. by Guanajuato; area, 3,429 sq. m.; pop. in 1869, 153,286. It occupies a part of the plateau of the Cordillera, and is traversed by numerous mountain spurs, but contains much fertile land. The rivers are all small, and the Rio de Montezuma and Lerma, on the frontiers, are the only streams that deserve notice. Gold, silver, copper, quicksilver, tin, lead, and antimony are found. Grain, tobacco, and the sugar cane are extensively cultivated; cotton is grown in some districts; and considerable numbers

of cattle are reared. The forests abound in fine timber and precious woods. Woollen and cotton goods, earthenware, and saddlery are manufactured, from materials produced mainly within its limits. The state is divided into the districts of Querétaro, San Juan del Rio, Amealco, Jalpan, Toliman, and Cadereyta; the chief towns besides the capital are San Juan del Rio and Toliman. **II.** A city, capital of the state, on a plateau upward of 6,000 ft. above the sea, 110 m. N. W. of Mexico; pop. in 1869, 48,237. It occupies the sides and summits of several hills, and is separated from its suburbs by a small stream. The streets are well laid out, the houses regular, and the city is one of the finest in the republic. The two parish churches are magnificently decorated, and there are 13 other churches. There are a college, a school of art, and an academy of design. The city is supplied with water by an aqueduct 2 m. long, which crosses a plain upon arches, some of which are 90 ft. high, and in connection with a tunnel brings the water a distance of 6 m. The manufactures consist chiefly of woollen and cotton goods, leather, soap, cigars, and pulque. Two miles from the city is the largest cotton mill in the country, employing 2,500 hands. In 1848 the Mexican congress ratified the peace between Mexico and the United States at Querétaro. In February, 1867, the emperor Maximilian having taken refuge in Querétaro, the town was besieged by Gen. Escobedo; on May 15 the emperor was captured, and on June 19 he and his two generals, Miramon and Mejia, were shot, on the Cerro de las Campanas, or hill of the Bells, which overlooks the town.

QUERINI, Girolamo, an Italian scholar, born in Venice, March 30, 1680, died in Brescia, Jan. 6, 1759. He became a Benedictine monk in Florence in 1698, assuming the name of Angelo Maria. In 1700 he came under the influence of Montfaucon; and after lecturing for some time in his convent on Hebrew and Biblical literature, he spent several years visiting the principal libraries of Europe, and returned to Florence in 1714. He was enjoined by the general chapter of his order to write a history of the Italian Benedictines, but was prevented after years of laborious research by Pope Clement XI., and published only a plan of his work with the title *De Monastica Italia Historia Conscribenda* (4to, Rome, 1717). The pope appointed him abbot of the Benedictine monastery in Florence. He was consecrated bishop of Corfu in 1723, and in 1727 bishop of Brescia and cardinal. He left Latin works on history, biography, and mathematics.

QUESADA. See XIMENES DE QUESADA.

QUESNAY, François, a French economist, born at Mérey, near Versailles, June 4, 1694, died in Versailles, Dec. 16, 1774. He began life as a surgeon, and in 1737 became perpetual secretary of the surgical academy; but in 1744 he obtained a diploma as a physician. He was a favorite medical attendant of the royal family and of

Mme. de Pompadour, and occupied rooms next to hers in the palace at Versailles. He published many works on medicine and surgery, which are now obsolete; and he is chiefly remembered as the father of the agricultural system of economy, called by him physiocracy. (See POLITICAL ECONOMY.) His *Tableau économique* (1758) was called by Laharpe "the Koran of economists." His economical works were edited by Dupont de Nemours, under the title *Physiocratie, ou Constitution naturelle du gouvernement le plus avantageux au genre humain* (Paris and Leyden, 1768; reprinted in the *Collection des principaux économistes*, Paris, 1846).

QUESNEL, Pasquier, a French theologian, born in Paris, July 14, 1634, died in Amsterdam, Dec. 2, 1719. He studied in the Sorbonne, became a member of the French congregation of the Oratory in 1657, and was appointed superior of the house of his order in Paris. Having imbibed the doctrines of the Port Royal theologians, he began to publish them in a series of moral commentaries on the gospel for the use of young Oratorians. The first volume appeared in 1671, entitled *Réflexions morales sur le Nouveau Testament*. He next published an edition of St. Leo the Great (4 vols. 4to, 1672), containing notes and commentaries favorable to Jansenism, followed by a commentary on the Acts of the Apostles and the Epistles, which was the continuation of the *Réflexions morales*. In 1681 he was banished to Orleans. Refusing to sign a theological formulary imposed on the Oratorians, he left the order in 1684, joined Arnauld in Brussels, and there published in 1694 a complete edition of his *Réflexions morales*. The angry controversies to which this book gave rise in France and the Low Countries caused Quesnel to be imprisoned by the Spanish authorities, but he escaped and found refuge in Amsterdam. The work was condemned by Clement XI., July 13, 1708, and still more solemnly in the famous bull *Unigenitus*, Sept. 8, 1713. Among Quesnel's other important works are: *Abrégé de la morale de l'Évangile* (3 vols., 1687); *Tradition de l'Église romaine sur la prédestination des saints et sur la grâce efficace*, under the pseudonym of Sieur Germain (4 vols., Cologne, 1687); *Discipline de l'Église tirée du Nouveau Testament et de quelques anciens conciles* (2 vols., Lyons, 1689); *Histoire abrégée de la vie d'Antoine Arnauld* (2 vols., Liège, 1699); *Justification de M. Arnauld* (3 vols., 1702); *La souveraineté des rois défendue contre Leydeker* (Paris, 1704); *Recueil de lettres spirituelles* (3 vols., 1721). There are several English translations of the *Réflexions morales*.

QUETELET, Lambert Adolphe Jacques, a Belgian statistician, born in Ghent, Feb. 22, 1796, died in Brussels, Feb. 17, 1874. When scarcely 18 years old he was appointed professor of mathematics in his native town, and five years later at the Athenæum in Brussels. In 1824 the king of the Netherlands sent him to Paris to

complete his astronomical studies; and on his return in 1826, he was charged with superintending the building of an observatory, of which he was director until his death. Between 1827 and 1829 he visited England, Scotland, Germany, Switzerland, and Italy. He was perpetual secretary of the academy of sciences of Belgium, president of the central statistical committee, and corresponding member of the French institute. His most important publications are: *Recherches sur la reproduction et la mortalité, et sur la population de la Belgique* (1832); *De l'influence des saisons sur la mortalité aux différents âges* (1833); *Sur la théorie des probabilités appliquées aux sciences morales et politiques* (1846); *Du système social et des lois que le régissent* (1848); *Sur la statistique morale et les principes qui doivent en former la base* (1848); and *Anthropométrie* (1873). From 1833 he published an *Annuaire de l'observatoire de Bruxelles*.

QUETZALCOATL (*i. e.*, the serpent or the twin with peacock or trogon feathers), the name of a mythical personage introduced into Mexican mythology by the Huastecas, a branch of the Mayas, who came, according to tradition, in boats along the coast and settled at Pánuco, without opposition from the former possessors, though in course of time they held their own against the Otomies, Nahoas, and Chichimecas, till they were finally conquered by the great monarch Nezahualcoyotl. The Natchez are supposed to have been also a part of this body of emigrants. This mythical personage appeared in a long white robe, holding a staff, and introduced the honors paid to the cross. He taught the people many arts, introduced a system of worship, and finally returned to Yucatan according to Mexican tradition, though in Yucatan, where he is known as Cuculcan, they make him return to Mexico. The accounts given of him are not always consistent, and may apply to a series who bore the name. He was ultimately honored as a god, and especially as the god of rain. The religious ideas introduced by him were not confined to the Huastecas, but extended to the whole Mexican empire.

QUEVEDO Y VILLEGAS, Francisco Gomez de, a Spanish author, born in Madrid, Sept. 26, 1580, died at Villanueva de los Infantes, Sept. 8, 1645. He was educated at the university of Alcalá, and took a degree in theology at the age of 15. Having killed a nobleman in a duel, he fled to Sicily, where the viceroy, the duke of Osuna, gave him honorable employment, and on his removal to Naples made him minister of finance. On visiting Madrid on diplomatic business, he was pardoned and received a pension. He was concerned in the conspiracy of the marquis of Bedmar against Venice (1618), and narrowly escaped from that city with his life. After the disgrace of his patron (1620) he was kept a prisoner at his country seat, La Torre de Juan Abad, for three years and a half, but was released without trial. He pub-

lished in 1631 a collection of the poetry of Luis de Leon, and *Poesías del bachiller de la Torre*, being probably the work of Quevedo himself. Being falsely accused in 1639 of writing some satirical verses which had been laid under the king's napkin at dinner, he was kept for nearly four years in rigorous confinement, where he contracted diseases from which he never recovered. His papers having been twice seized by the government, the greater part of his works have never been printed. Among his published writings are treatises "On the Providence of God;" "God's Politics and Christ's Government," in which he endeavors to collect a complete body of political philosophy from the example of the Saviour; "On a Holy Life;" "The Militant Life of a Christian," &c. His most celebrated works are his prose satires, more witty than delicate. Among these are his "History and Life of the great Sharper, Paul of Segovia" (1627); his treatise "On All Things, and many more;" "The Tale of Tales;" and "Letters of the Knight of the Forceps" (*Cartas del caballero de la Tenaza*, 1635). His *Sueños*, or "Visions," perhaps the most popular and effective of his satires, were published collectively in 1635, and translated into English by Sir Roger L'Estrange in 1708. A collection of Quevedo's poetry was made by Salas in 1648, another by Alderete in 1670, under the title of "The Spanish Parnassus, divided into two Summits, with the Nine Castilian Muses." There is a complete edition of his works by Sancho (11 vols. 8vo, Madrid, 1790-'94), and a later collection by Guerra y Orbe (Madrid, 1852). A translation of the satirical works appeared at Edinburgh in 1798.

QUICHÉS, Kichés, or Utlatecas, a semi-civilized nation of Guatemala, occupying at the time of the conquest the greater part of what is now called Los Altos, or the highlands of Guatemala, including the districts of Quiché, Totonicapam, and Quesaltenango. Their traditions indicate that they sprung from the Toltec stock. Their records, as written out by members of the royal house immediately after the conquest, give a long array of kings, and imply a high antiquity. It seems that the Kachiquels and Zutugils were once embraced in the Quiché kingdom, and that their separation was the act of the king Acxopil, who divided his power with his two sons, retaining to himself the capital and surrounding regions, which preserved the name of Quiché. These three divisions, subsequently becoming hostile, were easily conquered by the Spaniards. Alvarado encountered his most vigorous resistance in Quiché, where the king, Tecum-Umam, went out to meet him, according to the chroniclers, with 232,000 men. They fought with great bravery, but musketry and cannon, and above all the terror inspired by the Spanish horse, proved too powerful for the rude means of resistance at their command. The battle lasted six days, the Indians fighting desperately as they fell back. The king at last was slain by

Alvarado, and the subjugation of the Quichés was completed.—The ruins of the city of Quiché, described by Mr. Stephens, attest the grandeur and power of this people, and give a fair support to the early accounts of their numbers. The district which they occupied is the best populated portion of Guatemala, and is almost purely Indian, the ancient language being still in general use. The people are described by Arthur Morelet as "an active, courageous race, whose heads never grow gray, persevering in their industry, skilful in almost every department of art, good workers in iron and the precious metals, generally well dressed, neat in person, with a firm step and independent bearing, and altogether constituting a class of citizens who only require to be better educated to rise equal to the best." Their language is regarded as a purer dialect than either the Kachiquel or Zutugil, with which it is compared by Fray Ildefonso Flores, in his *Arte de la lengua Kachiquel* (Guatemala, 1753). Much has been done recently for a better knowledge of this people by Brasseur de Bourbourg, especially in his *Grammaire de la langue Quiché mise en parallèle avec ses deux dialectes Cakchiquel et Tzutuhil, avec un vocabulaire, servant d'introduction au Rabinal Achi, drame indigène* (Paris, 1862), and *Popul Voh, le livre sacré et les mythes de l'antiquité américaine, avec les livres héroïques et historiques de Quiché* (1861).

QUICHUAS, the dominant people in the empire of Peru under the incas, who made their language the general one of their territory. The Quichuas extended from Lake Titicaca to Quito, and toward the coast to the territory of the Chinchas and Yuncas. The Aymaras, extending from Lake Titicaca to what is now the southern limit of Bolivia, were first reduced by the Quichuas under the incas. The Quichuas are gay, cheerful, energetic, and under the wise sway of the incas seem to have risen rapidly in many arts. They were assiduous cultivators of the soil; maize and other grains raised in Titicaca were sent to all parts of the empire as sacred presents, and the inca himself gave an example of the honor of agriculture. They wove and spun the wool of the llama, vicuña, and alpaca; they worked mines of gold, silver, and copper; built suspension bridges; erected adobe houses with gables, niches, and arches, and temples of the same material or stone, cutting and fitting the blocks with an accuracy and finish that cannot be excelled; made sterile tracts productive by a wise and extended system of *azéguías* and aqueducts, and also by excavating till moisture was reached. In astronomy they had not reached as high a degree as the Mexicans; and in literature, though preserving records mainly by *quipus* or knotted cords, they cultivated poetry, and had dramas as well as touching songs that won the admiration of the Spaniards. The incas claimed to descend from the sun, and introduced the worship of that luminary. They reduced the

Chancas and Huancas, apparently intrusive eastern tribes, and then attacked the Yuncas, the people of the coast, whose capital was at Chimú near Trujillo, and who worshipped Pachacamac, creator of the world, of whom there was a famous idol and temple at the place that still bears the name, the god Rimac, who had a famous oracle near Lima, and other deities. After a long and bloody war the inca Capac Yupanqui overthrew Chuqui Manca, king of Chimú, and reduced the Yuncas. They were compelled to accept the sun worship, but the inca allowed the temple of Pachacamac to stand, as its fame was spread through most of South America. There are remnants of the Yuncas still retaining their language at Moche, Eten, &c.; it is entirely different from the Quichua. The priests of the sun dressed in white, and practised celibacy and fasts; near each temple was also a convent of virgins of the sun. The men wore woollen tunics and leggings, the women long skirts and short cloaks, joined by gold, silver, or copper clasps. The incas were distinguished by the *llautu*, a fillet with a ball descending between the eyes. After the Spanish conquest the Indians lost much of the arts they had gained, and retrograded generally. A desperate effort was made by the Quichuas in the last century to recover their freedom, but their leader, Tupac Amaru, a descendant of the incas, was taken and torn in pieces by horses in the plaza of Cuzco in 1780.—There is a series of grammars of the Quichua, beginning with that of Fray Domingo de San Tomas (Valladolid, 1560), and coming down to Markham, "Contributions toward a Grammar and Dictionary of Quichua" (London, 1864). *Ollantay*, a Quichua drama, and several songs of the *haravecs* or bards, have been published.

QUICKSILVER. See MERCURY.

QUIETISM. See MOLINOS.

QUILIMANE, or **Kilimane**, a town and military station in the Portuguese territory of Mozambique, on the E. coast of Africa, situated on the left bank of the river Quilimane, the N. arm of the Zambesi, 12 m. from the sea, in lat. 17° 45' S., lon. 36° 44' E.; pop. about 12,000. It is irregularly built, some of the dwellings being of brick, some of mud, and many of reeds and grass; but there are gardens, with orange and cocoanut trees, about many of the houses. Its principal trade is the export of slaves. The Portuguese garrison consists of a commandant, a few Europeans, and about 50 native troops. Quilimane is one of the very few places on the Mozambique coast actually occupied by the Portuguese, but it is very unhealthy and fast decaying.

QUILLWORT, a genus of cryptogamic plants so called from having some resemblance to a bunch of quills; they are mostly aquatics, and being evergreens, Linnaeus called the genus *isoëtes* (Gr. *ισος*, equal, and *ετος*, year); this is placed by some botanists in the family of club mosses (*lycopodiaceæ*), while others give it the rank of an order. The external appear-

ance of the plants is that of a tuft of linear leaves, attached by their enlarged bases to a very short rootstock, from the lower part of

Quillwort (*Isoetes lacustris*). A small plant of natural size; magnified bases of two leaves, showing macrospores and microspores; and macrospores greatly magnified.

which roots are produced. The organs of reproduction are curiously concealed; the sporangia or spore cases are orbicular or ovoid, plano-convex, and sessile in the axils of the leaves, the bases of which are hollowed out to receive and partly cover the sporangia, which are united to them by the back. The spores are of two kinds, those in the cases of the outer leaves being very much larger than those near the centre of the cluster. The large spores (macrospores) are from 20 to 200 in a spore case, and are divided into two hemispheres by a line, one of the halves being marked by three radiating lines; the minute spores of the inner leaves (microspores) are so small that it is estimated that each case contains over a million; they are obliquely oblong and triangular. Ten or a dozen species are found in the whole country, one of which, *I. lacustris*, occurs also in northern Europe and Asia, and is found along our northern border from New England to Lake Superior; it has 10 to 25 leaves, 2 to 6 in. long; the largest species, *I. Engelmannii*, has from 50 to 200 leaves, often 25 in. long. These singular plants are not rare, but they escape general notice from their resemblance to submerged grasses.

QUILOA. See KILWA.

QUIMPER, a town of France, capital of the department of Finistère, on the Odet, 32 m. S. E. of Brest and 13 m. from the Atlantic; pop. in 1872, 13,159. It is partly surrounded by ancient walls and watch towers. The cathedral of St. Brentin, begun in 1239 and finished in 1493, was rebuilt in 1858 from the designs of Viollet-le-Duc. There are ship yards, manufactories of pottery, fisheries, and trade in grain, horses, honey, and cattle. Formerly it was the capital of Cornouailles.

QUIN, James, an English actor, born in London, Feb. 24, 1693, died in Bath, Jan. 21, 1766. He was educated at the university of Dublin, and when 20 years old went to London, and began to study law in the Temple. Having obtained an engagement at Drury Lane, he at first acted subordinate parts, but gained some reputation in the character of Bajazet. In 1720 he secured his fame by acting Falstaff in the "Merry Wives of Windsor," and greatly increased it in 1731 by excelling Barton Booth in the part of Cato; and on the appearance of Garrick in 1741, he stood at the head of his profession. In 1748 he retired from the stage, thereafter residing at Bath, but performed Falstaff every year till 1753, refusing to play afterward because he had lost his voice. He received a pension from George III., whom in his youth he had instructed in elocution.

QUINARY SYSTEM. See ENTOMOLOGY, and ORNITHOLOGY.

QUINAULT, Philippe, a French dramatist, born in Paris, June 3, 1635, died there, Nov. 26, 1688. When about 18 years old he produced on the stage a five-act comedy, *Les rivaux*, which was received with applause. He studied law, married a rich widow, assumed the title of councillor before the parliament, and bought an office as auditor in the court of exchequer. In 1664 he produced *La mère coquette, ou Les amants corrigés*. *Astarte* (1663), his only tragedy which is now remembered, was ridiculed by Boileau. He wrote lyrical tragedies to which Lully furnished the music. He was elected a member of the French academy in 1670. His complete works were published in 1739 and 1778 (5 vols. 12mo).

QUINCE (the plural of old Eng. *coine*, from Fr. *coing*, which is derived from the Lat. *cydonia*, from the Cretan town of Cydonia), a

Apple-shaped Quince (*Pyrus Cydonia*).

tree long cultivated in temperate climates for its fruit, and which is found wild in southern Europe, northern Africa, and in various parts

of Asia. Arguments have been presented to show that the golden apples of the Hesperides were quinces instead of oranges; at all events the fruit was held in high esteem by the ancients, who had several distinct varieties. The quince has usually been placed in a separate genus, *Cydonia*, but modern botanists class it with the apple and pear in *pyrus*, and according to this view its botanical name (in most works given as *Cydonia vulgaris*) is *pyrus Cydonia*. The chief botanical difference between the quince and the apple and pear is, that it has numerous ovules in each cell and the seeds are surrounded by mucilage, while the others have only two ovules in the cell and are without mucilage. The quince seldom grows over 15 ft. high, and when left to itself is disposed to form a bush with numerous crooked branches rather than a tree; its oval or ovate deciduous leaves are entire, and covered with a cottony down on the under side. The flowers are produced singly at the ends of short branches of the current season, which bear five or six leaves, and appear late in spring; they have leafy calyx lobes, and large white or rose-colored petals. The large fruit is pear- or apple-shaped, very downy when young, but smooth when mature, of a fine golden yellow color, and very fragrant; the flesh hard, and in most varieties very austere and unfit for eating raw. The fruit is much used for preserves, and for making marmalade and jellies, and is sometimes added to apples which of themselves lack character in making pies and sauce. The seeds have long been used medicinally; their epidermis is so abundantly supplied with mucilage that one part of dry seed will coagulate 40 parts of water; it has but little adhesive power, and is regarded as a modification of cellulose. A decoction is used as a demulcent application, and is sometimes added to eye washes; the perfumed mucilage, called bandoline, was once a popular dressing for the hair.—The quince is a profitable fruit, though very much neglected; because it will give some returns when set in an out-of-the-way place and allowed to run wild, it is a popular impression that this is the proper treatment for it; the tree will abundantly repay good culture, and when properly trained to a tree form it is very ornamental both in flower and in fruit. The leading varieties are the apple- or orange-shaped and the pear-shaped. The first named under good cultivation sometimes reaches a pound in weight, and is often depressed-spherical in shape. The other has not only the more elongated form indicated by its name, but ripens two weeks later; its flesh is less tender than that of the apple-shaped variety. The Portugal is such a poor bearer that it is but little cultivated, though its fruit is of superior quality and turns crimson when cooked. Rea's seedling, which originated in Greene co., N. Y., and is but little known as yet, produces a fruit of excellent quality and from a third to

a half larger than any other. An important use of the quince is for stocks upon which to graft or bud the pear (see PEAR), which upon a quince root becomes much dwarfed and fruits very early. The ordinary varieties of quince do not answer for this purpose, as they are of too slow growth; two kinds are used, both of which originated in France, the Angers and the Fontenay or Paris quince, both of which bear fruit inferior in quality to those already named. The quince is easily propagated; cuttings taken off in the fall and set out at once, or kept buried till spring, root readily; it is also propagated by layering in the ordinary manner, and for the production of stocks for the pear by what is known as mound or stool layers. (See LAYERING.) To train the quince in the tree form, a shoot should be selected as a leader and kept tied to a stake until of the proper height, cutting off all the shoots which start below; when a strong stem is thus produced, it is to be cut back to a desirable height, and four or more branches allowed to grow to form the head.—The Chinese quince, *pyrus* (or *Cydonia*) *Sinensis*, is occasionally seen in cultivation; it is said to reach 20 ft. in China, but is here not more than half that height; its ovate leaves are acuminate at both ends, and smooth; its small flowers appear in May, are rosy red with a violet tinge, and quite ornamental; the fruit is very large, egg-shaped, and green, but useless, being hard and dry.—The Japan quince, *P. (Cydonia) Japonica*, was introduced into English gardens in 1815, and

Japan Quince (*Pyrus Japonica*).

has become one of the most popular ornamental shrubs. When trained to a wall it has reached 15 ft. high, but it is usually only 5 or

6 ft. and much branched, its spray being terminated by thorns. The oval leaves, somewhat wedge-shaped at the base, are serrate, smooth, and, with the conspicuous kidney-shaped stipules, very dark green. The flowers appear just before the leaves and in great abundance; in the ordinary form they are bright scarlet inclining to crimson, but there are garden varieties with white and blush flowers, and of several shades of red to dark crimson; also varieties in which the flowers are semi-double. The fruit somewhat resembles a small apple, is yellowish green, and has a very strong and rather agreeable odor; it is uneatable raw or cooked, but is sometimes put into drawers to perfume their contents. This is well suited for an ornamental hedge, as it bears clipping well and has remarkably clean and bright foliage; when in bloom nothing can be more brilliant. It is readily propagated by cuttings of the roots.

QUINCY, a town of Norfolk co., Massachusetts, on Quincy bay, and on the Old Colony railroad, 7 m. S. S. E. of Boston; pop. in 1830, 2,201; in 1840, 3,486; in 1850, 5,017; in 1860, 6,778; in 1870, 7,442. It is celebrated for its quarries of granite, large quantities of which are shipped to all parts of the country. It contains two national banks, with a joint capital of \$300,000; a savings bank, with more than \$1,000,000 deposits; eight schools, including a high school; a weekly newspaper; and nine churches. It is noted as the birthplace of Gov. John Hancock, and Presidents John Adams and John Quincy Adams. The principal village is beautifully situated on an elevated plain near the centre of the town. The most noteworthy buildings are the town house, of granite; the Adams temple, a granite church containing monuments in memory of John Adams and John Quincy Adams and their wives; and the Adams and Quincy mansions. Quincy was formed from Braintree in 1792.

QUINCY, the capital of Adams co., Illinois, and the second city in the state in population, situated on the Mississippi river, 160 m. above St. Louis and 95 m. W. of Springfield; pop. in 1837, 1,653; in 1850, 6,902; in 1860, 13,718; in 1870, 24,052, of whom 7,733 were foreigners and 1,073 colored; in 1875, estimated by local authorities at 35,000. It is handsomely situated on a limestone bluff 125 ft. above the river, of which and of the surrounding country it commands an extensive view. It is regularly laid out and well built, chiefly of brick, and has fine water works. The streets are lighted with gas, and the principal ones are traversed by horse cars. There are many substantial business blocks and handsome residences, the latter being surrounded by well kept grounds. It contains four small parks and several cemeteries. About 2 m. from the centre of the city are well appointed fair grounds comprising about 80 acres. The trade of Quincy is extensive, the river affording ample water communication, and eight lines of

railroad rendering tributary a wide and fertile region. The railroads centring here are: the Chicago, Burlington, and Quincy; Toledo, Wabash, and Western; Hannibal and St. Joseph, crossing the Mississippi on a magnificent railroad bridge recently completed; Quincy, Carthage, and Burlington; Quincy, Missouri, and Pacific; St. Louis, Keokuk, and Northwestern; Quincy, Alton, and St. Louis; and Missouri, Kansas, and Texas. The facilities for manufacturing are good. The various establishments employ an aggregate of about 3,500 hands, and produce annually goods to the value of about \$10,000,000. Among the more important are 10 manufactories of wagons and ploughs, 4 of furniture, 3 of carriages, 4 of plug tobacco, 1 of corn planters, 11 of brick, 2 of organs, 2 of canned fruit and pickles, 8 iron foundries (producing stoves and general castings), 11 flouring mills, 1 paper mill, 1 woollen mill, 4 planing mills, 2 grain and 2 fruit distilleries, 5 rectifying establishments, 6 breweries, and a grain elevator with a capacity of 150,000 bushels, besides manufactories of cigars, cooperage, soap and candles, files, hoes, sewing machines, matches, &c. Pork packing employs 7 firms, and 15 establishments are engaged in the gathering and shipment of ice. There are 7 banks, with an aggregate capital of \$1,000,000. Quincy is divided into 6 wards, and is governed by a mayor and a board of 12 aldermen. It has an efficient police force and a well organized fire department. The principal charitable institutions are two hospitals and three asylums. There are nine public schools, embracing a high school and grammar, intermediate, and primary departments, attended by about 3,000 pupils; also several academies. A medical college was incorporated in 1873. The Quincy library has 4,000 volumes. Three daily (one German), one tri-weekly, and four weekly (one German) newspapers, and two monthly (one German) periodicals are published. There are 30 churches, viz.: 4 Baptist (1 colored), 1 Christian, 1 Congregational, 2 Episcopal, 4 Evangelical, 2 Evangelical Lutheran, 1 Jewish, 6 Methodist (1 colored), 2 Presbyterian, 6 Roman Catholic, and 1 Unitarian.—The first white settler established himself on the site of Quincy in 1822. It was laid out in 1825 and incorporated as a town in 1834. It received a city charter in 1839.

QUINCY. **I. Josiah, jr.** (so called to distinguish him from his father, who survived him), an American lawyer, born in Boston, Feb. 23, 1744, died at sea off Gloucester, Mass., April 26, 1775. He graduated at Harvard college in 1763, and studied law. After the passage of the stamp act he denounced the oppressions of the parliament and its violations of the rights of the colonists, in public meetings and through the press. Though of a slender frame and imperfect health, he had a voice of great compass and beauty, and a graceful and passionate delivery. His name is associated with those of James Otis and Joseph Warren, as men who

were most powerfully influential in causing the revolution. On the arrest of Capt. Preston and the soldiers who fired upon the people in the "Boston massacre" of March 5, 1770, application was made on their behalf to Mr. Quincy and to John Adams to act as their counsel. This duty they accepted in the face of the strongest popular opprobrium, and on the trials the next autumn the acquittal of the prisoners justified their course. In 1773 Quincy on account of ill health sailed to Charleston, S. C., returning on horseback in the spring. During this tour he put himself in communication with the principal whigs of the southern and middle states, and established a plan of correspondence between them and the Massachusetts patriots. Besides his speeches in town meetings and other public assemblies, he made bold and animated appeals through the newspapers, under various signatures. In May, 1774, he published under his own name his principal political work, "Observations on the Boston Port Bill, with Thoughts on Civil Government and Standing Armies." In it he distinctly declares the inevitable necessity of the appeal to arms which soon followed, and plainly shadows forth independence as the necessary result. This work was republished in London, and excited much attention on the part both of ministerialists and the opposition. An attempt was made to deter him from publishing it by an elaborate letter sent to him anonymously, but believed to have proceeded from a high functionary of the government. To this letter he made a brief but spirited reply through the "Massachusetts Gazette," and forthwith proceeded with the publication. He was prevailed upon in September, 1774, to go to England on a private mission for the popular cause, as well as for the good of his health. This visit excited considerable notice in London. He had interviews, at their own request, with Lord North and Lord Dartmouth, and was in constant intercourse with Dr. Franklin, Col. Hartley, Gov. Pownall, the earl of Shelburne, Col. Barré, Dr. Priestley, Dr. Price, and other prominent friends of America. Lord Hillsborough denounced him in his place in the house of lords, as a man who, if the government did its duty, "would be in Newgate or at Tyburn." He prepared to return early in the spring of 1775, against the advice of his physician, but died just before arriving. Almost his last words were that he should die content could he have but an hour's interview with Samuel Adams or Joseph Warren. His "Reports of the Supreme Court of Massachusetts Bay, 1761-'72," was edited by S. M. Quincy (8vo, 1865). See also his life by his son Josiah Quincy (8vo, 1825; new ed., 1875). II. Josiah, an American statesman, son of the preceding, born in Boston, Feb. 4, 1772, died in Quincy, July 1, 1864. He received his early education at Phillips academy, Andover, and graduated at Harvard college in 1790. He studied law in Boston, and began practice in 1793. In 1804 he

was elected state senator, and in 1805 became a member of congress, where he served till 1813. During the whole of this period the federal party was in a hopeless minority; its only service was one of protest, and Mr. Quincy was its most prominent and efficient member in the discharge of this duty. The embargo, the war of 1812, the erection of the Orleans territory into a state, which were the chief public measures of that period, he encountered with the most untiring hostility. He was one of the first, if not the first, among northern men to denounce the slaveholding interest as a rising and dangerous tyranny. In 1813, having declined a reelection, he returned to private life, dividing his year between Boston and his country seat at Quincy. He was immediately elected a member of the state senate, and joined in the protest of the legislature against the war and the admission of Louisiana, and reported the famous resolution, occasioned by a proposed vote of thanks to Capt. Lawrence for the capture of the Peacock, to the effect that in a war waged without justifiable cause and for conquest and ambition, it was not becoming a moral and religious people to express approbation of exploits not immediately connected with the defence of the seacoast and harbor. He remained in the state senate till the close of 1820, when he was dropped by the federal managers under an impression that his uncompromising course had weakened his popularity, but was immediately elected to the house of representatives at the head of the ticket, and chosen speaker, which office he held while in the house. In 1822 he resigned to take the office of judge of the municipal court of Boston. He first laid down the law in the case of Joseph T. Buckingham, indicted for a libel on John N. Maffit, that the publication of the truth, with a good intention, and for a justifiable end, is not libellous. This ruling excited much censure at the time, but is now the acknowledged rule of law in this country and in England. In 1823 he left the bench to become mayor of Boston, being the second incumbent of that office, which he held till 1828, when he was chosen president of Harvard university. He was inaugurated in June, 1829, and held the post till August, 1845, when he resigned. In 1856 he took a prominent part in the effort to elect Fremont to the presidency. Besides many speeches in congress and orations on particular occasions (the chief of which are those on July 4, 1826, the jubilee of independence, on the second centennial celebration of the settlement of Boston, September, 1830, and the second centennial of Harvard university, September, 1836), Mr. Quincy published "Memoir of Josiah Quincy, jr., of Massachusetts" (Boston, 1825; new ed., 1875); "History of Harvard University" (2 vols., Cambridge, 1840); "The Journals of Major Samuel Shaw, the first American Consul at Canton, with a Life of the Author" (Boston, 1847); "The History

of the Boston Athenæum" (Cambridge, 1851); "The Municipal History of the Town and City of Boston during two Centuries" (Boston, 1852); "The Life of John Quincy Adams" (1858); and "Essays on the Soiling of Cattle" (1859).—See his life by his son Edmund Quincy (1867), who also edited his "Speeches delivered in the Congress of the United States" (8vo, 1875). **III. Edmund**, an author, son of the preceding, born in Boston, Feb. 1, 1808, died in Dedham, May 17, 1877. He graduated at Harvard college in 1827. He published "Wensley, a Story without a Moral" (Boston, 1854), and a "Memoir of Josiah Quincy" (8vo, 1867), and was a frequent contributor to periodicals and newspapers. He was long prominent among the Garrisonian abolitionists.

QUINCY, Quatremère de. See QUATREMÈRE DE QUINCY.

QUINET, Edgar, a French author, born in Bourg, department of Ain, Feb. 17, 1803, died in Paris, March 27, 1875. He studied German literature in Germany, and spent some time in Greece. He was professor at Lyons from 1839 to 1842, when he became the first incumbent of the new chair of the languages and literature of southern Europe at the collège de France. In 1846 he was suspended on account of his inflammatory lectures, but he was triumphantly reinstated after the revolution of Feb. 24, 1848, in which he took a part, and was returned to the constituent and legislative assemblies. In January, 1852, he was banished, and lived abroad till 1870, when he resumed his professorship. In 1871 he took his seat in the national assembly, and opposed peace with Germany and all cession of territory. He wrote much on the literature of Germany, France, and southern Europe, several books of travel, and many remarkable political pamphlets. His principal works are: *Ahasvérus* (1833); *Des Jésuites* (in conjunction with Michelet, 1843); *Les esclaves*, a dramatic poem (1853); *La révolution religieuse au XVII^e siècle* (1857); *Merlin l'enchanteur* (2 vols., 1860); *La révolution* (2 vols., 1865; 5th ed., 1868); *La création* (2 vols., 1870); and *L'Esprit nouveau* (3d ed., 1875).—His wife, a Moldavian lady, in 1868 published *Mémoires d'exil*.

QUINIC ACID. See KINIC ACID.

QUININE, or Quinia. See CINCCHONA.

QUINSY (*tonsillitis, amygdalitis, or cynanche tonsillar*; Fr. *esquinancie*), common inflammatory sore throat. Though called tonsillitis, the inflammation is rarely confined to the tonsils, but involves the pharynx, the soft palate, and the uvula, and sometimes extends to the root of the tongue. It commences with a feeling of dryness and discomfort about the throat, and with pain in swallowing. The mucous membrane lining the throat is reddened, and the tonsils are more or less swollen. As the disease advances, the inflamed parts, at first preternaturally dry, become covered with viscid mucus, and the distress of the patient is greatly enhanced by the efforts which he is

tempted to make to remove this secretion. In many cases suppuration occurs in one or both tonsils; when this takes place those organs are often enormously swollen, and together with the obstruction of the inflamed palate may render breathing difficult and painful. In such cases the febrile reaction is strongly marked, the skin being hot, and the pulse full and frequent; the patient is unable to take nourishment, and the voice becomes thick and characteristic of the disease. The pain, exceedingly acute when the patient attempts to swallow, or to clear his throat of the viscid matter which adheres to it, often extends to the ear, and is sometimes attended with partial deafness. The bursting of the abscess in the tonsil is at once followed by relief; the matter has a nauseous taste and often an exceedingly offensive smell. The disease, though very painful, is attended with little danger; but the inflammation may by extension involve the larynx and thus prove fatal, and cases are on record in which death has occurred from the ulceration having involved a branch of the carotid artery.—The disease requires but little treatment. Where the mucous membrane alone is involved, astringent gargles, repeated five or six times a day, usually give relief and tend to shorten the course of the inflammation. The food should be liquid (soups, beef tea, milk, &c.), and should be swallowed in large mouthfuls, which give less pain in deglutition than smaller ones. If an abscess forms in either or both of the tonsils, the greatest relief is obtained from frequent inhalations of warm steam, which acts as a poultice to the inflamed parts. As soon as the location of the abscess can be determined, it should be opened and the pus evacuated, after which there is usually no further trouble.

QUINTANA, Manuel José, a Spanish poet, born in Madrid, April 11, 1772, died there, March 11, 1857. He was educated at Salamanca and practised law for a time at Madrid; but he soon turned his attention to letters. His tragedy of *El duque de Visco* (1801), imitated from "The Castle Spectre" of M. G. Lewis, was not successful. In 1802 he produced a small volume of lyric poems, the patriotic spirit of which immediately brought them into favor; and in 1805 he placed upon the stage his *Pelayo*, intended to rouse his countrymen to resist foreign oppression, which was equally well received. His *Vidas de los Españoles célebres* (3 vols. 8vo, 1807-'34), and *Poesías selectas castellanas* (3 vols. 8vo, 1808), with critical notes, were prepared with the same patriotic motive. At the outbreak of the rising against the French in 1808 he published his *Odas a España libre*, and, both through the press and as secretary to the cortes and the regency, exerted himself to the utmost in behalf of his country; but after the return of Ferdinand VII. from France in 1814, Quintana was confined for more than six years in the fortress of Pamplona. He was delivered by the revolution of 1820, and after

its overthrow in 1823 he remained in Estremadura until the accession of Isabella II., whose education he superintended. In 1835 he was created a senator, and in 1855 crowned by the queen with laurel. His complete works have been published in Rivadeneyra's *Biblioteca de autores españoles* (1852).

QUINTILIAN (QUINTILIANUS), **Marcus Fabius**, a Roman rhetorician, born probably at Calagurris in Spain about A. D. 40, died about 118. He was educated at Rome, and was an advocate and teacher of eloquence. Among his pupils were the younger Pliny and the two grand-nephews of Domitian, by which monarch he was invested with the consular honors and title. He was the first public teacher of oratory who received from the imperial treasury a regular salary (100,000 sesterces a year), the endowment having been made by Vespasian. He continued his teaching for about 20 years, with the greatest success. His great work was *De Institutione Oratoria Libri XII.*, called also *Institutiones Oratorie*, which is both a complete system and a model of eloquence. There are 164 declamations falsely ascribed to him. The first complete manuscript of the "Institutes" was discovered by Poggio Bracciolini in the monastery of St. Gall. The *editio princeps* was printed at Rome by Lignamine (fol., 1470); the best edition is that by Spalding and Zumpt (6 vols. 8vo, Leipzig, 1798-1829). The "Institutes" have been translated into English by Guthrie (2 vols. 8vo, London, 1756), by Patsall (2 vols., 1774), and by Watson (2 vols., 1856).

QUINTUS CURTIUS RUFUS. See CURTIUS.

QUINTUS ICLILIUS. See GUISCHARD.

QUITCLAIM, a word often used in deeds, and usually in connection with words of grant and conveyance, when the grantor or seller intends to convey to the grantee or buyer all the right, title, interest, and estate of the grantor, but without any warranty whatever, whether of title, quantity, or anything else. Sometimes a deed purports to be a deed of "grant and quitclaim," when the grantor adds to the words of grant and conveyance words of limited warranty: as, for instance, warranty against himself and all persons claiming by, from, through, or under him. Even this limited warranty, and still more a general warranty, would estop the grantor from ousting the grantee by any better title, not coming through the grantee, which was outstanding at the time, and which the grantor might acquire subsequently. But if the deed were one of grant and quitclaim only, without any warranty, the grantor might then assert such a title. For example, A sells and conveys to B, by grant and quitclaim only, for a full price, an estate to which it turns out A has no title. But A subsequently acquires title to it by inheritance from the true owner. A may now recover the estate from B; but not if he granted with warranty, because if he then took the estate by his better title, B would turn round upon him on the warranty

and get the estate back again. Quitclaim is also used in receipts, usually with such words as release and discharge, when it is intended to signify that the party giving the receipt or release agrees never to make any claim against the other party for any existing demand.

QUITMAN, a S. W. county of Georgia, separated from Alabama by the Chattahoochee and drained by Pataula creek and other streams; area, 190 sq. m.; pop. in 1870, 4,150, of whom 2,377 were colored. The surface is undulating and the soil productive. It is traversed by a branch of the Southwestern railroad. The chief productions in 1870 were 79,610 bushels of Indian corn, 4,151 of oats, 15,615 of sweet potatoes, and 3,880 bales of cotton. There were 287 horses, 473 mules and asses, 1,734 cattle, and 2,828 swine. Capital, Georgetown.

QUITMAN, John Anthony, an American politician, born in Rhinebeck, Dutchess co., N. Y., Sept. 1, 1799, died in Natchez, Miss., July 17, 1858. He studied law in Ohio, and in 1821 settled in Natchez, Miss. In 1827 he was elected to the legislature, from 1828 to 1834 was chancellor of the state, and afterward president of the state senate. In 1836 he raised a small body of men to aid the Texans, and after the capture of Santa Anna returned to Natchez, where he became major general of militia and filled several local offices. In July, 1846, he was appointed brigadier general in the United States army, and ordered to report to Gen. Taylor at Camargo. At the battle of Monterey he distinguished himself by his successful assault on Fort Tenerice, and his daring advance into the heart of the city. At the siege of Vera Cruz he commanded in the first sharp engagement, and subsequently led an expedition against Alvarado, in conjunction with the naval forces under Com. Perry. He was with the advance under Gen. Worth that took possession of the city of Puebla, where he was brevetted major general and received a sword voted to him by congress. At Chapultepec he stormed the formidable works at the base of the hill, pushed forward to the Belen gate, which he carried by assault, and took possession of the city of Mexico, of which the general-in-chief on his arrival appointed him governor. After establishing order and discipline he returned to the United States, and was soon after, almost by acclamation, elected governor of Mississippi. Being threatened with arrest for alleged complicity with Gen. Lopez in organizing an expedition to Cuba, he resigned his office and went to New Orleans in the custody of the United States marshal; but after an abortive effort to obtain evidence, the prosecution was abandoned. The democratic party in Mississippi immediately renominated him for governor, but he withdrew from the contest when the people, at an election for delegates to a state convention, condemned his opposition to the compromise measures. In 1855 he was elected to congress, and in 1857 reelected without

opposition. During his whole term he was at the head of the military committee. His parliamentary fame rests chiefly on his celebrated speech for the repeal of the neutrality laws, and his argument on the powers of the federal government, which made him the recognized head of the state rights party. His life has been written by J. F. H. Claiborne (2 vols. 12mo, New York, 1860).

QUITO, a city of Ecuador, capital of the republic, and of the province of Pichincha, in a district of its own name formed by a valley in the Andes; lat. $0^{\circ} 13' S.$, lon. $78^{\circ} 43' W.$; pop. about 70,000. Built upon the slopes of several hills on the E. flank of the volcano Pichincha, at an elevation of nearly 10,000 ft. above the sea, it has but two approaches from the south and one from the north, the eastern and western portions being hemmed in by precipitous mountains. The streets are narrow and mostly unpaved, and the houses, owing to the frequency of earthquakes, are generally of one story. Many houses are built on arches over two deep ravines which traverse the town from E. to W., through which rush down torrents of melted snow from the neighboring volcanoes, and which here and there present dangerous precipices. Water is distributed by pipes in the houses of the rich, and by handsome stone fountains embellishing the public squares. The principal public edifices are the cathedral, archiepiscopal palace, city hall, and government house, all in the Plaza Mayor, one of the finest public squares in South America. Most of the churches are attached to large convents. There are three hospitals, one being for elephantiasis, asylums for the blind and the insane, a university once famous for the number of its students, a seminary, a college, and a number of public and private schools. An academy of arts and sciences, and schools of agriculture, obstetrics, and sculpture, were to be organized in 1873. Quito has several libraries, chief of which is that of the old Jesuit college, with about 20,000 volumes. The mint occupies part of the same structure as the university. The climate is salubrious; the mean annual temperature is about $60^{\circ} F.$, and the extremes 45° and 75° . Elephantiasis is very common. The foreign commerce is mostly in produce sent to Central America, and some precious metals to Peru, all by the

port of Guayaquil. The manufactures include coarse cottons and woollens; there are a few silk-weaving establishments, the raw material for which is mainly imported from France, but recent attempts to acclimatize the silkworm bid fair to prove successful. The women make very fine gold lace, and excellent embroidery, needlework, and lace. Quito communicates with Bogotá by a good road, the only one worthy the name in the republic before the commencement of a carriage road to lead from Guayaquil to Quito, save in the space between Sibamba and Pueblo Nuevo, over which a railway is to extend. There is a telegraph from Quito to Guayaquil.—The history of Quito goes back to a remote antiquity. Of its primitive rulers, tradition preserves the names of a number who were called Quita. About A. D. 280 the city is said to have been captured by certain foreign invaders, who, under the name of Siris, maintained their dominion until the invasion of the inca Huayna Capac, who subdued the entire kingdom. At his death he divided his kingdom between his two sons, Atahualpa and Huascar, leaving to the first the sceptre of Quito, and to the second that of Cuzco. War ensued between the brothers, in which Atahualpa obtained control of all the provinces. But his triumph was of short duration, and he lived to find himself the prisoner of the Spanish adventurer Pizarro. Taking advantage of the capture of his king, Rumiñagui, one of the inca generals, usurped regal authority in Quito, but fled to the mountains on the approach of Sebastian Benalcázar. Under the Spanish dominion Quito, erected into a presidency, first formed part of the viceroyalty of Peru; afterward it was attached to that of Santa Fé, and subsequently restored to that of Peru, to which it remained attached until the independence of the country, when it was aggregated with Venezuela and New Granada in the republic of Colombia. On the dissolution of that republic in 1831, it was organized, with the districts of Asuay and Guayaquil, into a new republic under the name of Ecuador. The modern city was founded in 1534 by Benalcázar; it was incorporated as a city in 1541, and erected into a bishopric four years later. Several disastrous earthquakes have occurred here, especially those of Feb. 4, 1797, and March 22, 1859.

R

R, THE 18th letter and 14th consonant of the English alphabet. It is a lingual and a liquid or semi-vowel, being pronounced both before and after most other consonants. It is found in all languages except the Chinese and the tongues of some of the North American Indians. The Romans borrowed it from the Greek *rho* (P, ρ), which is derived from

the Hebrew and Phœnician *resh*. It is one of the last which children learn to pronounce, and those who have been engaged in teaching persons deaf from birth to articulate find the greatest difficulty in conveying any idea of its sound to their pupils. The most common mode of pronouncing it is by an expiration while the tongue touches the roof of the mouth with a

tremulous motion, as in the word *rhetoric*. The tremulous sound is more distinct in the Spanish *rr*, which indeed is not readily learned by Englishmen or Americans. It is frequently exaggerated by the Irish and softened down by the English, who are more easily distinguished by their peculiar pronunciation of this letter than by that of any other.—The Romans often added an *r* to words which they borrowed from the Greek, as *νύξ*, *nurus*; *μύαξ*, *murex*; and on the other hand they often dropped it from the nominative case of nouns and retained it in the oblique cases, as *αἶς*, *αῖς*; *οἶς*, *οῖς*. It was interchanged sometimes with *s*, the words *arena*, *laribus*, *pignora*, *Furii*, *Valerii*, and *Papirii* having been anciently written *asena*, *lasibus*, *pignosa*, *Fusii*, *Valesii*, and *Papisii*. The same change is observed in some modern languages, as Eng. *hare*, Ger. *haase*; Eng. *was*, Ger. *war*. It is most frequently interchanged however with *l*. The Chinese, who cannot pronounce *r*, always use *l* in its place; the Japanese do exactly the reverse. (See L.)—As a Roman numeral R denotes 80, or with a dash over it (\bar{R}) 80,000. The Greek P with a dash over it stands for 100, and with a dash under it for 100,000. As an abbreviation, R signifies *Roma*, *Romanus*; R. P., *res publica*; R. C., *Roma condita*.

RAAB (Hung. *Győr*). I. A W. county of Hungary, in the Trans-Danubian circle, bordering on Presburg, Comorn, Veszprém, Oedenburg, and Wieselburg; area, 1,590 sq. m.; pop. in 1870, 103,637, chiefly Magyars. The surface is level, except in the south. The extensive marsh of Hanság is in the western portion. The chief rivers are the Danube and the Raab. The principal products are corn, wine, fruits, cattle, and sheep. II. A city (anc. *Arrabona* or *Rabona*), capital of the county, in an extensive plain at the junction of the Rabnitz and Raab, near the entrance of the latter (which rises in Styria) into an arm of the Danube, known as the Little Danube, 67 m. W. N. W. of Buda; pop. in 1870, 20,035, including about 5,000 Germans. The old cathedral has been restored and embellished, and the episcopal palace is a striking building. The academy of law was reopened in 1867, and the city has a theological faculty and a Catholic and a Protestant gymnasium. In the vicinity is the Benedictine abbey of Szent-Márton (Martinsberg), one of the oldest in Hungary. In the 10th century the town regained the importance which it once possessed as a Roman colony in Pannonia, and it was generally kept in a state of defence by the Hungarian kings, but suffered during their warfare with the emperors of Germany. The Turks took it in 1595, and were expelled in 1598 with great loss, by Schwarzenberg and Pálffy. The fortress was finally razed in 1820. The Hungarian army of "insurrection" (defensive rising *en masse* of the nobility) was defeated in the plain of Raab by Eugene Beauharnais, June 14, 1809. In 1848-'9 it was strongly fortified

by the Hungarians, who were here defeated by the Austrians under Haynau, June 28, 1849.

RABANUS (or **Hrabanus**) **MAURUS**, a German theologian, born in Mentz about 776, died at Winkel in 856. He was educated in the Benedictine convent of Fulda, and continued his studies in Tours under Alcuin, who gave him the surname of Maurus in honor of St. Maurus. He returned to Fulda in 804, founded there the first public convent school in Germany, and labored especially for the spread and improvement of the German language. He wished to free the German church from the influence of Rome, and succeeded in introducing the rule that the clergy should only preach in the native tongue. He has also the merit of having given a new impetus to Biblical research by requiring the study of the original tongue of the New Testament. These innovations drew upon him the displeasure and suspicion of the clerical party, and though finally elevated to the rank of an abbot, he laid down his office in 842 to live in the priory of St. Peter; but in 847 he resumed teaching, and was consecrated archbishop of Mentz. Among his works is *Glossaria Latino-theodisca*, which is now an important monument of the earliest phase of the German language. He wrote also *De Universo*, *De Arte Grammatica Prisciani*, and several other theological treatises. His works (exclusive of the *Glossaria*) were published by Calvenerius (6 vols. fol., Cologne, 1627).

RABAT, a town of Morocco, in Fez, on a bay of the W. coast, at the mouth of the Burekrag or Bu-Regreb, opposite the town of Salé; pop. about 20,000, including many Jews. The custom house and the minaret of the principal mosque are remarkable specimens of Moorish architecture; most of the other Moorish buildings are in decay, and there are many houses built in European style. Rabat was founded in the 13th century, and together with Salé was long notorious as a haunt of pirates. The imports in 1874, chiefly cotton goods, amounted to \$58,000, and the exports, chiefly of wool (exclusive of specie), to \$27,000.

RABBATH-AMMON. See PHILADELPHIA (Palestine).

RABBI (Heb., my master, lord, or teacher), a title of honor bestowed on the doctors of the Jewish law since the 1st century B. C. The Hebrew or Aramaic words *rab*, *rabba*, *rabbān* (master), *rabbōni* (my master), and *rabbenu* (our master), have also been employed in the same sense. The title *rabbi* or *rabbīn* is frequently applied to the Talmudic writers, the Jewish theological writers of post-Talmudic times (see HEBREWS), whose dialect is therefore called rabbinical, and the religious heads of Jewish congregations. The Jews of eastern Europe and others attach *Rab*, both in conversation and writing, to the name of every married Jew of good reputation.

RABBIT, the common name of several species of the hare family, especially the *lepus cuni-*

culus of Europe and the *L. sylvaticus* of North America; the family and generic characters have been given under HARE. The European rabbit or cony (*L. cuniculus*, Linn.), the *lapin* of the French, is about 16½ in. long, with the tail 3 in. additional, and the ears also 3 in.;

European Rabbit or Cony (*Lepus cuniculus*).

the tarsus shorter than in the hare; the general color gray brown, white below, the back of the neck rufous; tail white below, blackish above, but pencilled with dirty white; ears not tipped with black; compared with that of the hare, the skull has the muzzle, inter-orbital space, and incisive openings narrower; the mammae are five pairs, two pectoral and three ventral. In the wild state the rabbit inhabits Europe, except the more northern portions, and N. Africa; it is thought to be originally from Spain, but, being hardy, has been carried to most parts of the world; it is easily distinguished from the hare by its smaller size, grayish color, and short feet and ears; it also differs from the hares in its burrowing habits. Unable to escape from its enemies by speed, it seeks safety in deep holes dug in dry sandy places, living in society in what are called warrens, with an ample supply of food, in places suitable for burrows, such as sandy heaths covered by a prickly furze. Remaining concealed by day, they come out at twilight in search of food, and often do considerable mischief by digging up the newly sprouted corn and gnawing the bark from young trees; these warrens are often of large extent, and a source of great profit from the flesh and skins of the animals, which are caught in snares and traps, dug or drowned out, and hunted by dogs and ferrets. They begin to breed at the age of six months, have several litters in a year and five to eight at a time; the period of gestation is about three weeks, but, as the uterus is double, there may be two distinct litters at an interval of a few days; the young are born blind and naked, in a nest lined with the mother's soft fur; they are said to live eight or nine years. They seem to have social laws, the same burrow being transmitted from parent to children, and enlarged as the family increases. Rabbits and hares appear to be

natural enemies; they are not found in the same localities, and when they meet they generally engage in combat; when brought up together they do not produce a fertile offspring *inter se*, and hybrids probably never occur between them in the natural state. It has been estimated that in four years a single pair of rabbits would, if unmolested, become the progenitors of more than 1,250,000; but this increase is checked by the persecution of man and of carnivorous beasts and birds. Their ravages are more than counterbalanced by their flesh, which forms a nutritious and easily digested food, and by their skins, which are used in making hats and are dyed to imitate more expensive furs. The name rabbit or cony is erroneously applied in the translation of the Hebrew Scriptures to the *shaphan*. (See HYRAX.) Rabbits are easily domesticated, and in this state vary greatly in colors, size, and character of fur; black, white, and gray are the prevailing colors; in the silver-gray variety the hairs are white and black; the Angora rabbit is noted for the length and softness of its white fur; in the lop-eared varieties the size is three or four times that of the wild animal, and the ears are more or less bent downward from the base. When tame they do not pair like those in a wild state, and lose more or less the instinct of burrowing; their flesh is also inferior in flavor, though more delicate and digestible; the tame males not unfrequently kill the young.—The American gray rabbit (*L. sylvaticus*, Bach.) is about 16½ in. to the root of the tail, and 26½ in. to the end of the outstretched legs, the tail to the end of the hairs 2¾ in.; fur and pads of the feet full and soft; on the back light yellowish brown, lined with black, grayer on the sides; on the rump mixed ash, gray, and black, pure

American Gray Rabbit (*Lepus sylvaticus*).

white below; upper surface of tail like the back, below pure cottony white; posterior edge of ears whitish, edges of the dorsal surface toward the tip black, the rest ashy brown; fur lead-colored at the base. This is among the largest of the short-eared *leporidae* of America,

being largest in the west and smallest and coarsest-haired in the south; it is found almost throughout the United States, from the southern parts of New Hampshire to Florida, and west to the upper Missouri, being most abundant in sandy regions covered with pines. It also frequents woods and thickets, concealing itself in its form, in thick bushes, or in holes in trees or under stones by day, coming out at night to feed; in clover and corn fields, vegetable gardens, and nurseries of young trees, it does much mischief. It does not dig burrows like the European rabbit, and comes rather in the class of hares; when pursued it runs with great swiftness and with few doublings to its hole in a tree or rock; though it will breed in enclosed warrens, it does not become tame, and has not been domesticated. It is very prolific, or else it would be exterminated by its numerous enemies; it often runs into the hole of the woodchuck, skunk, fox, or weasel, in the last three cases often falling a victim to the inhabitant of the burrow; it is hunted by dogs, shot from its form, and caught in snares and traps; its flesh is much esteemed. It somewhat resembles the European rabbit in its gray color, but it does not change its colors like the latter, and is smaller and more slender. Hybrids are sometimes produced between this species and the domesticated European rabbit which has escaped from confinement into the woods. The sage rabbit (*L. artemisia*, Bach.), from the west and the plains of Mexico and Texas, cannot be satisfactorily distinguished from the last species. The jackass rabbit or Texan hare (*L. callotis*, Wagl.) is so named from its very long ears, measuring about 5 in., though the animal is rather smaller than the European hare; it is yellowish gray above, waved irregularly with black, upper part of tail black, sides gray, and dull whitish below; nape sooty black; it is found in Mexico, Texas, and Oregon, and on the plains. The long and slender legs indicate rapid locomotion and a capacity for making long leaps; it is a solitary and not very common species, and has not been found in California.

RABELAIS, François, a French author, born in Chinon, Touraine, about 1490, died about 1553. He was educated at the convent of Seuillé and the monastery of La Baunette, and was ordained as a priest in 1511. He then made up for former idleness by devoting himself to the study of ancient and modern languages, mastering the Latin, Greek, Italian, Spanish, German, English, Hebrew, and Arabic. Greek had especial attraction for him; and this involved him in serious quarrels with his fellow monks, who were fiercely hostile to the study. The ill feeling grew so strong that in 1524 he obtained permission from Pope Clement VII. to enter the order of Benedictines. He spent several years in their house at Maillezais, but in 1530 abandoned monastic life and repaired to Montpellier to study medicine. In 1532 he was a physician at Lyons,

and published annotated and corrected editions of Hippocrates, Galen, and others. From 1533 to 1550 he published several editions of a facetious production, in which he endeavored to destroy faith in astrology. At Lyons also he published the first rough sketch of the strange work upon which his fame rests: *Les faits et dictz du géant Gargantua et de son fils Pantagruel* (1533). Jean du Bellay, his old schoolmate, bishop of Paris and afterward cardinal, having been appointed French ambassador to Rome, engaged Rabelais as his physician, and obtained for him from Pope Paul III. a bull, dated Jan. 17, 1536, remitting the penalties which he had incurred by the abandonment of his order. He then became a member of the abbey of St. Maur des Fossés at Paris, where he remained till 1542, when he was presented with the comfortable living of Meudon. Here he applied himself faithfully to the duties of his ministry, and devoted his leisure hours to the completion of his great work, three books of which had already appeared. This being done in 1551, he went again to Paris, published the fourth book, and spent his later years at Meudon. Such are the ascertained facts of a life which has been egregiously misrepresented. No performance in French literature had greater success in its time, or has since attracted so much attention, as his "Gargantua and Pantagruel." It is a ruthless attack upon monks, princes, kings, and all ecclesiastical and civil authorities. Amid its chaos of eccentricities and allusions to persons and events, of good sense and folly, of delicate thoughts and gross obscenities, commentators have tried in vain to unravel the work. According to the best authorities, Gargantua stands for King Francis I.; Grandgousier for Louis XII.; Pantagruel for Henry II.; Picrocole for Maximilian Sforza, duke of Milan; Gargamelle for Anne of Brittany, the queen of Louis XII.; Badebec for Claude of France, queen of Francis I.; Grandejument de Gargantua for Diana of Poitiers; Panurge for the cardinal de Lorraine; and Frère Jean des Entemeurs for Cardinal du Bellay. Be this as it may, "the work was entirely in accordance with the taste of his age," as Vinet remarks; "and excellent minds which could appreciate its fine parts were also delighted with those that are repulsive to our taste." Lord Bacon called Rabelais "the great jester of France;" others have called him a "comic Homer." More than 60 editions of the work have been published; that of Burgaud des Marets and Rathery (2 vols. 12mo, Paris, 1857-8) is the most convenient and acceptable, with a good biographical and critical notice, explanations, notes, &c. There are several English translations. That of Sir T. Urquhart (1653; reprinted by the Maitland club, 4to, 1838) was adopted by both Ozell and Motteux as a basis. Their united translation is often reprinted; the last edition is by Bohn (2 vols., London, 1850). Sixteen private let-

ters of Rabelais were published in 1651.—See Ginguené, *De l'autorité de Rabelais dans la révolution présente et dans la constitution civile du clergé, ou Institutions royales, politiques et ecclésiastiques tirées de Gargantua et de Pantagruel* (Paris, 1791).

RABIES. See HYDROPHOBIA.

RABUN, the N. E. county of Georgia, bordering N. on North Carolina and E. on South Carolina, from which it is separated by the Chattooga river; area, about 320 sq. m.; pop. in 1870, 3,256, of whom 119 were colored. The surface is mountainous; the Blue Ridge forms the W. boundary and then curves through the N. portion of the county. The chief productions in 1870 were 4,080 bushels of rye, 71,376 of Indian corn, 2,704 of Irish potatoes, 3,915 of sweet potatoes, 4,208 lbs. of tobacco, 5,541 of wool, and 19,868 of butter. There were 481 horses, 470 mules and asses, 1,170 milch cows, 453 working oxen, 1,855 other cattle, 4,086 sheep, and 6,672 swine. Capital, Clayton.

RACCOON (*procyon*, Storr), a genus of American plantigrade mammals of the bear family, of the section *subursinæ*. In this genus the size is comparatively small, the body stout, and the tail moderately long, bushy, and not prehensile; the muzzle is pointed, and the end very movable and slightly projecting; the teeth are: incisors $\frac{3}{2}$ — $\frac{3}{2}$, canines $\frac{1}{2}$ — $\frac{1}{2}$, premolars $\frac{4}{2}$ — $\frac{4}{2}$, and molars $\frac{3}{2}$ — $\frac{3}{2}$, in all 40, there being one upper true molar on each side less than in the bears. The shape is not unlike that of the badger, though the legs are longer; ears moderate, erect, and covered with hair; head broad behind and flat, with naked and large muffle; whiskers in four principal horizontal series, five or six bristles in each; feet five toed, with naked soles and no indication of webs; claws curved, not retractile, and sharp; though

brown; an oblique black patch on the cheeks, continuous with a paler one beneath the jaw, and another behind the ears; the end of muzzle, ears, and posterior part of cheek patch whitish; tail bushy, with the tips and five rings black, and the nearly equal interspaces rusty white; hind feet 4 in. long, dirty white above, the fore feet $2\frac{1}{2}$ in.; mammae six, ventral; there are anal glands which secrete a somewhat offensive fluid. Some varieties occur nearly black, others are nearly white. The raccoon is found generally over the United States, as far north as lat. 60° in the interior, as high as Newfoundland on the Atlantic, and further north on the Pacific; it is most abundant in the southern states, frequenting retired swamps covered with high trees and well watered. It is an excellent climber, in this way obtaining eggs and young birds; watching the soft-shelled turtle lay her eggs in the sand, it uncovers and devours them; it seizes ducks as they come to the water, and is extremely fond of ripe and juicy corn, as well as of frogs and shell fish. It is not entirely nocturnal, and sometimes visits the corn fields and the poultry yard at midday; it feeds much on an inferior oyster in the southern states, hence called the raccoon oyster; it also eats rabbits, squirrels, and other rodents, fish, nuts, and honey. It has been generally supposed to dip its food in water before eating it, hence its specific name of *lotor* or washer; but this, which it does not generally do in captivity, according to Bachman, is probably only an occasional habit. It hibernates during the coldest weather in the northern states. It is shy, and has an acute sense of smell; it brings forth about the month of May, in a nest in a hollow tree, four to six at a time, about the size of half-grown rats, which utter a plaintive infant-like cry. It is a favorite sport of the southern negroes in winter to hunt "coons," driving them to a tree, and then climbing up and shaking them off, or felling the tree to bring them within reach of the dogs; they sell the skin to the hatters, and eat the flesh, which is generally very fat and tender, with a flavor of pig. Many are caught also in traps, and are hunted by torchlight. In captivity it makes a very cunning and interesting pet, being easily tamed so as to follow its master even into the crowded street, ambling along in the manner of a bear, and adroitly picking his pockets of dainties. The crab-eating raccoon (*P. cancrivorus*, Illig.), from Brazil and the northern parts of South America, is longer and more slender than the common species, grayish above shaded with brown and black, and yellowish below; the face is whitish, with a black band surrounding each eye; tail less distinctly annulated. Its habits are nearly the same as in the other species, but it is more arboreal; it is equally omnivorous; its flesh is also used as food. It is found on the seacoast and in the interior, and as far south as Paraguay.

RACHEL, in Biblical history. See JACOB.

Raccoon (*Procyon lotor*).

plantigrade when standing, the gait is rather digitigrade. The common raccoon (*P. lotor*, Storr) is 22 or 23 in. long, with the tail about a foot additional; the general color is grayish white, the tips of the long hairs black and giving this tint to the back; under surface dark

RACHEL (*Élisabeth Rachel Félix*), a French actress, born at Mumpf, Switzerland, Feb. 28, 1820, died at Cannet (near Toulon), France, Jan. 3, 1858. She was the daughter of a Jewish peddler, whom she accompanied as a strolling singer and guitar player. While singing in a café in Paris she attracted the attention of Achille Ricourt, a theatrical manager and writer on art, and of Choron, who in 1831 began to give her instruction in music. As she showed a great talent for the stage, he transferred her to the care of Saint-Aulaire, under whom she made rapid progress in elocution. Her personation of Hermione at a private performance procured her admission in 1836 as a pupil of the conservatory; and on April 24, 1837, she appeared at the Gymnase theatre in *La Vendéenne*, a vaudeville written for her by Paul Dufourt. She attracted little attention, and for more than a year did not again appear prominently. In the mean time she studied assiduously under Samson, and on Sept. 7, 1838, produced a great sensation as Camille in Corneille's *Les Horaces* at the Théâtre Français. The long neglected plays of Corneille, Racine, and Voltaire were speedily revived for her, and she became best known as Eriphile in *Iphigénie*, Aménaïde in *Tancrède*, Roxane in *Bajazet*, Pauline in *Polyeucte*, as Athalie, and especially as Phèdre and Camille. She was also much admired in other parts, such as Joan of Arc, Mary Stuart, and Adrienne Lecouvreur; and during the excitement of 1848 she produced a great effect by her peculiar rendition of the *Marseillaise*. She excelled most in the impersonation of lofty classical heroines and in the delineation of the fiercer emotions, and was celebrated for the magnetism of her gestures and voice, her singular air of distinction, dignity, grace, and repose, and her wonderful identification with the characters she represented. Her income, originally 4,000 francs, soon rose to 80,000; and in 1849 she effected an arrangement at the Théâtre Français, by which six months of absence in each year were allowed her. The receipts from her performances in the French provinces and in England reached enormous sums, and in Russia in 1853 she received 400,000 francs. In 1855, in company with her brother Raphaël Félix, her sisters Sarah, Lia, and Dinah, and a complete troupe, she gave performances in New York, Boston, and other cities of the United States, and then went to Havana to regain her strength; subsequently she spent some time in Egypt, and finally sought relief in southern France; but all attempts to arrest the progress of her disease (consumption) proved unavailing. Rachel was slender, rather tall, with a finely modelled head, clear, pale complexion, and features capable of the greatest variety of expression. She died unmarried and a Jewess, but left two sons, who were educated as Catholics.

RACINE, a S. E. county of Wisconsin, bordering on Lake Michigan; area, about 350 sq.

m.; pop. in 1870, 26,740. It is watered by several streams, and is traversed by the Chicago, Milwaukee, and St. Paul, the Chicago and Northwestern, and the Western Union railroads. The surface is nearly level, and the soil productive. Limestone is found. The chief productions in 1870 were 339,739 bushels of wheat, 376,398 of Indian corn, 393,127 of oats, 25,983 of barley, 164,219 of potatoes, 164,321 lbs. of wool, 610,228 of butter, and 43,070 tons of hay. There were 5,395 horses, 7,257 milch cows, 6,747 other cattle, 37,620 sheep, and 7,423 swine; 12 manufactories of agricultural implements, 6 of boots and shoes, 5 of brick, 13 of carriages and wagons, 22 of clothing, 2 of iron castings, 3 of lime, 8 of saddlery and harness, 3 of sash, doors, and blinds, 2 of woollens, 7 flour mills, 8 tanneries, 6 currying establishments, 6 breweries, and 3 planing mills. Capital, Racine.

RACINE, a city and the county seat of Racine co., Wisconsin, on Lake Michigan, at the mouth of Root river, and on the Chicago and Northwestern railroad, 23 m. S. of Milwaukee and 62 m. N. of Chicago; pop. in 1860, 7,822; in 1870, 9,880; in 1875, 13,282. It is built on a plateau projecting about 5 m. into the lake and elevated about 40 ft. above its level. The climate is cold in winter and cool and bracing in summer; the mean annual temperature is about 44°. The streets are wide and cross each other at right angles, the principal ones being bordered by shade trees. Main street is the business thoroughfare, and its upper portion is lined with elegant residences. The city is connected with Rock Island, Ill., by the Western Union railroad. The harbor is one of the best on the lake, and is accessible by vessels drawing 14 ft. A considerable tonnage is owned here, and the lake commerce is important. The lumber trade is large and increasing. Manufacturing is the chief interest, and to this Racine owes most of its wealth and prosperity. The value of products in 1874 was \$4,179,265. The principal establishments are 8 wagon factories, 8 carriage factories, 5 fanning-mill works, 10 tanneries, 2 trunk factories, 5 harness and saddle factories, 3 sash and blind manufactories, 3 foundries and machine shops, 6 saw mills, a paper machine factory, a woollen mill, a wire manufactory, a wagon lock manufactory, a manufactory of threshers, a linseed oil mill, a basket factory, and a silver-plating factory, besides many other establishments. There are two national banks, with a joint capital of \$400,000, two elevators, a dredge company, and seven hotels. The assessed value of property in 1875 was \$4,200,000. The public schools are excellent, and the Roman Catholics have a flourishing academy. Racine college, under the control of the Episcopalians, was founded in 1852. The buildings are situated in handsome grounds, 10 acres in extent, at the upper end of Main street. The institution comprises a collegiate department, with classical and scientific courses, and

a grammar school, with classical and mathematical courses. In 1874-'5 it had 18 instructors, 180 students, of whom 135 were in the grammar school, and a library of 3,000 volumes. Four weekly newspapers are published, of which one is in the Bohemian language. There are 24 churches.—Racine was first settled in 1834. The first post office was established in 1836; the first steamer entered the harbor in 1844. It was incorporated as a city in 1848. Its growth has been rapid.

RACINE, Jean, a French dramatist, born at La Ferté-Milon, Île-de-France, Dec. 21, 1639, died in Paris, April 22, 1699. He studied at the college of Beauvais, at Port Royal, and at the college of Harcourt. He won the friendship of Boileau and Molière and the good will of Louis XIV., who gave him a pension in 1660 for his ode on occasion of his marriage. His reputation as a dramatic poet of remarkable genius was firmly established in 1667 by his *Andromaque*, and in rapid succession appeared *Les plaideurs*, a comedy (1668), *Britannicus* (1669), *Bérénice* (1670), *Bajazet* (1672), *Mithridate* (1673), *Iphigénie en Aulide* (1674), and *Phèdre* (1677). The last, one of his masterpieces, was so coldly received, owing to the intrigues of his enemies, that he ceased to write for the stage, and devoted himself exclusively to his duties as official historiographer of the reign of Louis XIV. At the suggestion of Mme. de Maintenon he wrote in 1689 *Esther*, a Biblical drama, for the young ladies at the seminary of St. Cyr, where it was performed, and in 1691 *Athalie*, which was only recited, and not performed at the Théâtre Français until a much later period. Boileau regarded this as one of his finest productions, and it is still used in schools as a model of dramatic eloquence. In 1697 appeared his memoir on the unhappy condition of France, which he had written at the request of Mme. de Maintenon. Louis XIV. was displeased with it, and Racine's death is said to have been hastened by his grief on this account. He left some prose writings, which are marked by terseness, perspicuity, and eloquence. The last quality is peculiarly striking in his speech before the academy on the reception of Thomas Corneille (Jan. 2, 1685), when he paid a warm tribute to the genius of Corneille's illustrious brother. His miscellaneous poems also possess high merit. The most valuable complete editions of his works are by Pierre Didot the elder (3 vols. fol., Paris, 1801-'5), richly illustrated and forming part of the magnificent Louvre editions; by La Harpe (7 vols. 8vo, 1807); Geoffroy (7 vols., 1808); Aimé Martin, with notes from the principal commentators (7 vols., 1820); and Mesnard (5 vols., 1865-'9), to be completed in 7 vols., and to form part of the new editions of *Les grands écrivains de la France*, under the direction of Adolphe Régnier.—Racine's second son, Louis (1692-1763), wrote two didactic poems, *La grâce* and *La religion*, remarkable, especially the latter, for elegance, but deficient in most

other respects; they are chiefly intended to vindicate the principles of Jansenism. His *Mémoires sur la vie et les ouvrages de Jean Racine* (2 vols., 1747) is a more valuable performance. Among his other works is a prose translation of Milton's "Paradise Lost."

RADCLIFFE, Ann, an English novelist, born in London, July 9, 1764, died there, Feb. 7, 1823. Her maiden name was Ward. At the age of 22 she married Mr. William Radcliffe, a student of law, who afterward became editor and proprietor of "The English Chronicle," a weekly newspaper. Her first novel, "The Castles of Athlin and Dunbayne" (1789), gave little indication of her powers, though it had the wild and improbable plot and the unnatural characters which distinguish her later writings. "The Sicilian Romance" (1790) is much better, and the "Romance of the Forest" (1791) is sufficient to place her at the head of all writers of melodramatic romance. "The Mysteries of Udolpho" (1794) is generally regarded as her masterpiece. About the time this work was produced she made a tour through Germany, and in 1795 published "Journey through Holland," &c., with some observations on the lake district of England. Her last novel, "The Italian," which deals with racks, tortures, dungeons, confessionals, monks, and inquisitors, appeared in 1797. After her death there were published "Gaston de Blondville, a Romance," "St. Alban's Abbey, a Metrical Tale," and some poems, together with a memoir by T. N. Talfourd (4 vols., 1826); and a collection of her poems appeared in 1834.

RADCLIFFE, John, an English physician, born in Wakefield, Yorkshire, in 1650, died at Carsalton, near London, Nov. 1, 1714. He graduated at University college, Oxford, in 1669, studied medicine, and in 1675 began to practise in Oxford. In 1682 he received the degree of M. D., and in 1684 removed to London, where he soon acquired an extensive practice. He was appointed principal physician to the princess Anne in 1686, and in 1713 was elected to parliament by the town of Buckingham. Many anecdotes are recorded of his wit and rudeness of speech, which sometimes verged upon brutality. He bequeathed nearly his whole fortune to public uses, dividing it mostly between University college, Oxford, and the foundation at Oxford of a library with especial reference to medical science. This is known as the Radcliffe library.—See "Life and Letters of Dr. Radcliffe," by W. Pitts (8vo, London, 1736).

RADETZKY, Joseph Wenzel, count, an Austrian general, born at Trzebnitz, Bohemia, Nov. 2, 1766, died in Milan, Jan. 5, 1858. He was in active service from 1784, and in 1805 was made a major general. He contributed much to the victory at Aspern and Essling, May 21 and 22, 1809, and commanded the Austrian cavalry at the battle of Wagram, having been raised to the rank of lieutenant field marshal. After the peace he was made chief of the quartermaster general's staff, and councillor of the minister of

war, in which capacity he had a large share in the reorganization of the army. In the campaigns of 1813-14 and 1815 he was chief of the staff of Field Marshal Schwarzenberg, had an important share in the victory at Kulm, and was severely wounded at the battle of Leipsic. In 1831 he took command of the Austrian troops in Italy, and in 1836 was made field marshal. During the revolution of 1848, though an octogenarian, he evinced remarkable vigor and equal ability as a commander. From March 18 to March 23 combats between the Austrian troops and the insurgents constantly took place in the streets of Milan. On the latter day Radetzky evacuated the city and retreated behind the Mincio, with his headquarters at Verona; but the advance of Charles Albert at the head of a large army compelled him to retire behind the Adige. After the reduction of Peschiera by the Sardinian army, May 30, he feigned a general retreat, reduced Vicenza, Treviso, and Padua, thus securing his rear, and rapidly returned to Verona. His victory at Custoza (July 25) forced the Piedmontese to retreat, and from this time the success of the Austrians was assured. Milan capitulated on Aug. 6, and an armistice of six weeks was agreed upon between Sardinia and Austria. Charles Albert having resumed hostilities in March, 1849, Radetzky invaded Piedmont, and on March 23 gained the decisive victory of Novara. He now marched against Venice, which after a protracted siege finally surrendered, Aug. 23. Radetzky was made governor general and military commander of the whole country, the duties of which situation he performed with unmitigated rigor. On Feb. 28, 1857, at the age of 90, he retired from command.

RADIATA, or **Radiates**, next to the *protozoa* the lowest of the great branches of the invertebrates, whose characteristic feature is that of radiation from the mouth as a centre. All live in the water, and most are marine. They were divided by Agassiz into polyps, aculephs or jelly fishes, and echinoderms, the last class the highest, which have been described under these titles respectively. As they are among the lowest in rank in the animal kingdom, they are among the earliest in time. Huxley divides the old branch of radiates into the subkingdom *coelenterata*, including the hydroids, sea anemones, corals, and aculephs; and (in part) the subkingdom *anneluloida*, including the echinoderms. In the latter subkingdom he places also the intestinal and some minute aquatic worms, an association not generally accepted by naturalists. His classification, in detail, is as follows: Subkingdom *coelenterata*, having the alimentary canal communicating freely with the body cavity; with no heart or circulating system, and in most with no nervous system. Class A, *hydrozoa*, with walls of the digestive sac not separated from those of the body cavity, with the reproductive organs external; containing subclasses I., *hydroida* (hydroid zo-

ophytes), with orders: 1, *hydrida* (hydra); 2, *corynida* (tubularia); 3, *sertularida* (sea fir); II., *siphonophora* (oceanic), with orders: 4, *calycophoridae* (diphyes); 5, *physophoridae* (Portuguese man-of-war); III., *discophora* (jelly fish), with order 6, *medusida*; IV., *lucernarida* (sea blubbers), with orders: 7, *lucernariadae*; 8, *pelagida*; 9, *rhizostomida*; V., *graptolitida* (extinct). Class B, *actinozoa*, with stomach opening into body cavity, which is divided into compartments by vertical partitions, and with reproductive organs internal; with orders: 1, *zoantharia*, with rounded tentacles in multiples of five or six, as the sea anemones, star and brain corals, and madrepores; 2, *alcyonaria*, with fringed tentacles in multiples of 4, as *alcyonium*, tubipores, sea pens, and red coral; 3, *rugosa* (extinct); 4, *ctenophora*, oceanic jelly fishes like Venus's girdle and *pleurobrachia*. In the subkingdom *anneluloida*, the alimentary canal is shut off from the body cavity, and there is a distinct nervous system, generally a blood-circulating system, and a water-vascular system. The only class which concerns the radiates is the *echinodermata*, with the five living orders of crinoids, ophiurans, star fishes, sea urchins, and holothurians, and the two extinct low orders of blastoids and cystoids, allied to crinoids.—See papers on "The Mode of Growth of the Radiates," by Prof. Packard, in the "American Naturalist," March, 1875, *et seq.*

RADIOPHONY. See supplement.

RADISH (Lat. *radix*, root), a cruciferous plant, *raphanus sativus* (Gr. *rá*, quickly, and *pháveiv*, to appear, in allusion to its rapid germination), long cultivated for its edible root. The plant has rough and lyrate lobed leaves, the flowers purple or whitish and with the structure common to the family; but the pods differ from those of the other common *cruciferae* in being divided into cells by fleshy false partitions. The radish is a hardy annual of which the nativity is uncertain, but it was in cultivation in Egypt in very early times; being valued for its root only, all improvement has been directed toward that part, and it presents a great number of varieties, from the size of a small olive up to those weighing several pounds, and in shape from long and tapering to those much broader than long; some varieties are of very rapid growth, and must be eaten when very young, while others require as long to mature as turnips, and are kept all winter. The radish is to be regarded as a condiment rather than a nutritious food; in common with cresses, horseradish, and others of the family, it possesses a highly pungent principle which contains nitrogen and often sulphur; and with the others it is regarded as possessing antiscorbutic properties. The summer varieties in ordinary culture are sown as early in spring as the soil can be prepared, but they may be had much earlier by sowing in a frame, or at any time during winter if a hot-bed is used. In market gardens, where the greatest econo-

my in land is practised, it is customary to sow a bed with beets in regular drills, and then scatter radish seed over the bed broadcast and rake it in; the radishes are gathered before the slowly germinating beets need attention; they do best upon a light warm soil that has

Varieties of Radish. 1. Chinese Winter. 2. Olive-shaped. 3. Long. 4. Turnip-shaped.

been heavily manured for some crop the previous year. In some localities a fly (*anthomyia raphanum*) makes their culture impossible; its larva, a small white maggot, is very destructive. The turnip-shaped and olive-shaped, the French breakfast, and long scarlet are the leading early sorts, and the catalogues give many others, including white and other colors. The winter varieties are sown late in July or early in August in the latitude of New York, and harvested before freezing weather; to keep them fresh, they should be packed in earth or sand. The black and white Spanish are most common, but the rose-colored Chinese is by far the best.—The rat-tailed radish is probably a distinct species (*R. caudatus*); its root is not edible, but the pods, which are 2 ft. or more long, are used for pickles, and by some liked when dressed in the manner of asparagus.—The wild radish (*R. raphanistrum*), also called jointed charlock, has yellow flowers and necklace-formed pods with a long beak; this is a common weed in European agriculture, and has firmly established itself in some of our older states; it has much the same general appearance as the true charlock (*brassica sinapisrum*, or *sinapis arvensis* of most authors), from which it is readily distinguished by its jointed pods, which when quite ripe often break up between the seeds. In 1860 M. Carrière, a French horticulturist, published an account of his experiments in improving the wild radish, and found that a careful selection gave him in four generations edible roots of as varied forms as are presented by the garden radish.

RADNORSHIRE, a county of S. Wales, bordering on Montgomery, Shropshire, Hereford, Brecknock, and Cardigan; area, 432 sq. m.; pop. in 1871, 25,430. The chief towns are Presteign, Knighton, Radnor, and Rhayader. The Wye is the principal river. The surface is mountainous, the highest point being 2,163 ft. above the sea; but the S. E. part is in general level. A great portion of the county consists of common bog and moor land. Numbers of small ponies are reared. The county was anciently inhabited by the Silures.

RADOM, a government of Russian Poland, bordering on the governments of Kielce, Piotrków, Warsaw, Siedlee, and Lublin, and bounded S. E. by Austrian Galicia; area, 4,768 sq. m.; pop. in 1870, 532,466. It is drained by the Pilica and Vistula, which bound it on the north and west, and east and southeast respectively, and their affluents. The soil is diversified, and the surface the most elevated in the kingdom of Poland, being mountainous in the S. E. part. The government of Kielce on the southwest was separated from it in 1866. The capital, Radom, is in the N. part on a small tributary of the Vistula, 60 m. S. of Warsaw; pop. in 1867, 10,944.

RADOWITZ, Joseph Maria von, a Prussian statesman, born at Blankenburg, Brunswick, Feb. 6, 1797, died in Berlin, Dec. 25, 1853. His ancestors had emigrated from Hungary. He was instructed by his mother as a Protestant, and subsequently by his father as a Catholic. He entered the army in 1813, and was wounded and captured at the battle of Leipsic. In 1815, after the restoration of peace, he settled in Cassel as a teacher of mathematics and military science at the school of cadets, and was attached in the same capacity to the household of Prince Frederick William, the future elector. In 1823 he returned to the Prussian army with the rank of colonel, and in 1845 he became general. His great influence over the crown prince, the future king Frederick William IV., gave him a prominent position, and after holding various diplomatic offices and prompting the king in 1847 to make important organic changes in the government, he retired from the army in 1848, and went to Frankfort as leader of the ultra conservatives in the German parliament. His views, however, underwent a gradual change, and he became an advocate of a constitutional monarchy and of the union of North Germany under the king of Prussia. In 1849-'50 he was foremost in Berlin and Erfurt in the general direction of affairs, and from Sept. 27 to Nov. 29, 1850, he was minister of foreign relations. He retired from this office in consequence of the opposition to his plan of a rupture with Austria. His principal works are: *Gespräche aus der Gegenwart über Staat und Kirche* (1846); *Deutschland und Friedrich Wilhelm IV.* (1848); and *Neue Gespräche aus der Gegenwart* (2 vols., 1851). His *Gesammelte Schriften* comprise 5 vols. (1852-'3).

RADZIWILL, the name of a family long distinguished in Lithuania and Poland. Nicholas IV., surnamed the Black, prince of Olyka and Nieswicz, the founder in the 16th century of the modern branch of the family, promoted the reformation, and published in 1563 the Radziwill Bible; but his sons returned to the Catholic church. One of them, Prince Christopher, made a pilgrimage to Jerusalem, of which an account has been published (Polish, Breslau, 1847; Latin, Braunsberg, 1861). He appropriated 5,000 ducats for the purchase of copies of his father's Protestant Bible, intending to destroy them. Among the other members of this family was Michael Jerome (Geron) (1778-1850), an associate of Kosciuszko in the war of independence of 1794, and of Dombrowski in 1807. During the Russian campaign of 1812, Napoleon nominated him general on the battle field. In 1831 he was for a short time commander-in-chief of the patriot army, and after its defeat by the Russians he was detained by them till 1836. Subsequently he resided in Dresden.

RAEBURN, Sir Henry, a Scottish painter, born in that part of Edinburgh formerly called Stockbridge, March 4, 1756, died July 8, 1823. He was apprenticed to a goldsmith, but obtained his release, and began portrait painting in Edinburgh, where he soon became a rival of David Martin, who then stood at the head of this branch of the art. After visiting Rome he returned to Edinburgh in 1787, and at once became the leading portrait painter there, a supremacy which he maintained until his death. Among his sitters were Sir Walter Scott, Henry Mackenzie, Dugald Stewart, Lord Eldon, George IV., Prof. Playfair, Dr. Hugh Blair, Jeffrey, and Alison. In 1814 he was elected an associate and in 1815 a member of the royal academy; and in 1822 he was knighted.

RAFF, Joachim, a German composer, born at Lachen, Switzerland, June 27, 1822. He devoted his early years to science and literature quite as much as to music. In 1843 he published a number of light pieces for the pianoforte, which met with such success that he renounced his career as a school teacher and gave himself up to the art of music. Removing to Weimar, he wrote under the auspices of Liszt, for the theatre of that city, an opera entitled *König Alfred*, which possessed no decided merit. He has since resided in Cologne, Stuttgart, and Wiesbaden, devoting himself to musical composition and to writing upon musical topics. He is one of the most prolific composers of the present day, having published about 200 pieces, mostly for the pianoforte. The works upon which his reputation chiefly rests are his six symphonies, among which the *Leonore* and *Im Walde* are most noted.

RAFFAELE. See RAPHAEL.

RAFFLES, Sir Thomas Stamford, an English official, born at sea, off Jamaica, July 5, 1781, died July 4, 1826. He was an assistant clerk in the India house at the age of 15, and in 1805

was appointed under secretary to the new government formed by the East India company at Penang. In 1807 he became chief secretary; but intense application to business affected his health, and in 1808 he was compelled to go to Malacca. By his advice an expedition was fitted out against Batavia in 1811, and when that place was captured he was appointed lieutenant governor of Java and its dependencies. He held this office for five years, during which slavery was abolished. He was knighted in 1817. In 1818 he was made lieutenant governor of Fort Marlborough at Bencoolen, Sumatra, and remained there six years, emancipating the slaves. He established the British settlement at Singapore, and founded a college there for the encouragement of Anglo-Chinese and Malay literature. The state of his health compelled him in 1824 to resign and return to England. On his homeward voyage his ship was burned, and his natural history collections were lost. He founded the zoological society, and was its first president. He published a "History of Java" (2 vols. 4to, London, 1817), and "Malayan Miscellanies" (2 vols. 8vo, Bencoolen, 1820-'22). His "Life and Remains" was edited by his widow (4to, 1830).

RAFFLESIA, a remarkable genus of apetalous, exogenous plants, named in honor of Sir Stamford Raffles. While making a tour in the interior of Sumatra, Dr. Joseph Arnold, one of the suite of Raffles, was called aside by a native to see a fine flower, and was the first European to examine the largest flower known. A drawing was made, and, with portions of the reproductive organs preserved in spirits, sent to England, where Robert Brown described it as a new genus and called it in honor of those engaged in the discovery *Rafflesia Arnoldi*; since then three or four other species have been found, all smaller than the first, and this genus and a few others form the order *Rafflesiaceae*, all of them parasites. The species of *rafflesia* are all natives of Sumatra and

Rafflesia Arnoldi.

the neighboring islands, and parasitic upon the roots and branches of species of *vitis* related to the grape. The plant consists solely of a flower, subtended by a few bracts, and directly sessile upon the stem of its host. The flower first appears as a small knob upon the vine,

which gradually enlarges, and at the end of several months the fully developed bud looks like a monstrous cabbage. The perianth is tubular below, with five entire thick lobes; the throat of the flower is surrounded by a thick and fleshy ring; within the cup or tubular portion are the stamens or pistils. In *R. Arnoldi* the flower is flesh-colored, marked with yellowish white protuberances, and the interior of the cup is of an intense purple color. The flower measures fully 3 ft. across and weighs 15 lbs.; its cup is estimated to hold 12 pints. In this as in other species the flower gives off a most repulsive odor of tainted meat, which is however attractive to insects, large numbers of which hover about it, and as the plant is dioecious they no doubt aid in its fertilization. There are several plants of the order *Rafflesiaceæ* in South America and a solitary species in the United States, described by Gray as *pilostyles Thurberi*, found upon the Gila river in Arizona; this is parasitic upon a leguminous shrub (*Dalea*), and though of the same family and having the same habit of growth with the rafflesia just described, it is as remarkable for its minuteness as that is for its Titanic proportions, the whole plant being barely a quarter of an inch across.

RAFINESQUE, Constantine Smaltz, an American botanist, born of French parents in Galata, a suburb of Constantinople, in 1784, died in Philadelphia, Sept. 18, 1842. He came to America in 1802, collected a large number of botanical specimens, and in 1805 went to Leghorn, and thence to Sicily, where he remained ten years. While there he published three scientific works in French. Sailing for New York in 1815, he was wrecked on the coast of Long Island, and lost his collections and labors for 20 years. He became a teacher, made a tour to the west in 1818, and was for a time professor of botany in Transylvania university, Lexington, Ky. Finally he settled in Philadelphia, and established in 1832 "The Atlantic Journal and Friend of Knowledge," of which only eight numbers appeared. He published "Annals of Kentucky" (8vo, Frankfurt, 1824); "Medical Flora of the United States" (2 vols. 12mo, Philadelphia, 1828-'30); "The American Nations, or Outlines of a National History" (2 vols. 12mo, 1836); and "A Life of Travel and Researches" (1836). He also wrote many smaller botanical and zoological works, several of which were left unfinished; and he needlessly introduced so many new genera and species as to produce great confusion. "The Writings of C. S. Rafinesque on Recent and Fossil Conchology" has been edited by W. G. Binney and G. W. Tryon, jr. (8vo, Philadelphia, 1864).

RAFN, Carl Christian, a Danish archæologist, born in Brahesborg, island of Fünen, Jan. 16, 1795, died in Copenhagen, Oct. 20, 1864. He was educated at the university of Copenhagen, of which in 1821 he was made an assistant librarian. He undertook a general revision of

all the Icelandic and Norwegian manuscripts yet unpublished, belonging to the collection. Through his exertions in 1825 the "Society for Northern Antiquities" was founded, the principal object of which was to publish those manuscripts which could throw light on the obscure passages of Scandinavian history. It has published many volumes on the history and antiquity of the North. The work which excited the most attention was the *Antiquitates Americanae, seu Scriptores Septentrionales Rerum Ante-Columbianarum in Americæ* (Copenhagen, 1837), prefaced by a summary in English, in which he attempted to prove that the Scandinavians discovered America in the 10th century, and that from the 11th to the 14th they made frequent voyages thither, and effected settlements in what is now Massachusetts and Rhode Island. An important sequel to this work is *Denkmäler Grönlands* (3 vols., 1838-'45). He also published *Antiquités russes* (3 vols., 1850-'54).

RAGATZ, a watering place of Switzerland, in the canton of St. Gall, adjoining Pfäfers, and situated at the junction of several railways and at the mouth of the gorge through which the Tamina flows into the Rhine. It is one of the so-called indifferent thermal springs used for rheumatism and nervous diseases, and the place is generally overcrowded in summer. It has a fine bathing establishment, with terrace gardens to which water is conveyed from Pfäfers in wooden pipes. It contains an English chapel and a monument of Schelling, who is buried in the Catholic cemetery.

RAGLAN, Fitzroy James Henry Somerset, baron, an English general, born Sept. 30, 1788, died in camp before Sebastopol, June 28, 1855. He was the eighth and youngest son of the fifth duke of Beaufort. He was educated at Westminster school, and at the age of 16, being then known as Lord Fitzroy Somerset, entered the 4th regiment of dragoons as ensign. In 1805 he became lieutenant, and in 1809 was attached to the staff of the duke of Wellington as aide-de-camp and military secretary. At Busaco he was wounded, and at the storming of Badajoz he was one of the first to enter the town. At Waterloo he lost his right arm. For these services he was made colonel and knighted. In 1818 and 1826 he was elected to parliament, where he acted with the moderate Tories. In 1852 he was made master general of the ordnance, and created Baron Raglan. In the Crimean war he was commander-in-chief with the rank of field marshal, and on Sept. 20, 1854, fought the battle of the Alma. The sufferings of the troops during the following winter and the disastrous repulse of June 18, 1855, weighed upon his mind, and aggravated an attack of cholera, of which he died.

RAGOTZKY. See RÁKÓCZY.

RAGUET, Condy, an American political economist, born in Philadelphia, Jan. 28, 1784, died there, March 22, 1842. He was of French descent, was educated at the university of Penn-

sylvania, and for 18 months studied law. Afterward entering the counting house of a merchant, at the age of 20 he was sent to Santo Domingo as supercargo of a vessel. There he spent four months, and on his return published "A Short Account of the Present State of Affairs in St. Domingo." After a second voyage to the same island in 1805, when he remained eight months, he published "A Circumstantial Account of the Massacre in St. Domingo." In 1806 he went into business in Philadelphia, and was highly successful. During the war of 1812 he took an active part in providing for the defence of the city. From 1822 to 1827 he resided in Rio de Janeiro, at first as United States consul, and from 1825 as chargé d'affairs to Brazil. After his return to the United States he edited several journals devoted to free-trade doctrines. He published "An Inquiry into the Causes of the Present State of the Circulating Medium of the United States" (8vo, Philadelphia, 1815); "Principles of Free Trade" (1835); and a treatise "On Currency and Banking" (1839), which was republished in England, and translated into French.

RAGUSA (Slav. *Dubrovnik*), a town of Dalmatia, on a small peninsula of the Adriatic, at the foot of Mt. Sergius, 40 m. N. W. of Cattaro; pop. in 1870, 8,678. It has several towers and old walls, and the streets are connected by steps, the principal being the Corso. It is the seat of a Roman Catholic bishop, and has several Catholic and Greek churches. The cathedral, built by Richard Cœur de Lion, contains Titian's "Assumption of the Virgin." The town is strongly fortified and of strategical importance. The number of vessels entering in 1872 was 519, tonnage 12,208. The harbor is small and exposed to the sirocco. The port for larger vessels is at Gravosa, or Santa Croce, 2 m. from Ragusa, where are many fine villas and a new and large ship yard. —Ragusa was founded in the 7th century, after the destruction of Ragusa Vecchia (the ancient Greek colony Epidaurus, now a small village 7 m. S. E. of the present town). In the middle ages it was a republic, and was successively under Greek, Venetian, Hungarian, and Turkish protection. In the 15th century it had a population of 40,000, which declined in consequence of the plague, earthquakes, and the diversion of trade to other places. In 1807 it was occupied by the French under Gen. Lauriston, who soon after stood here a famous siege by the Russians and Montenegrins. Napoleon made Marmont duke of Ragusa, and incorporated it with the new kingdom of Illyria, with which in 1814 it passed to Austria.

RAGUSA, a town of Sicily, in the province of Noto, 30 m. S. W. of Syracuse; pop. in 1872, 21,546. It is built on a steep ridge, and consists of Ragusa Superiore and Ragusa Inferiore, with separate municipalities. In the Capuchin convent are pictures by Novelli. The town has large cotton factories. There are ancient remains, probably of Hybla Minor.

RAHWAY, a city of Union co., New Jersey, on Rahway river, here navigable by small craft, at the head of tide, 5 m. above its mouth in Staten Island sound, 16 m. in a direct line S. W. of New York; pop. in 1870, 6,258. It is a station on the Pennsylvania railroad, and another railroad is in course of construction by the Rahway railroad company to connect with New York and Long Branch. The streets are well laid out, and are lighted with gas. There are numerous fine residences, surrounded by handsome gardens. Water works supply the city on the direct pressure plan, obviating the necessity of fire engines. It is chiefly noted for its extensive carriage factories, of which there are 15 or 20. There are also a printing-press manufactory, two wool-scouring establishments, a manufactory of paper hangings, and some minor establishments. The city contains two national banks, several hotels, five public schools, a male and female institute, numerous private schools, a public library of about 5,000 volumes, two weekly newspapers, and 16 churches.—Rahway was first settled about 1720, and was incorporated as a city in 1858.

RAIKES, Robert, an English philanthropist, born in Gloucester in 1735, died April 5, 1811. He was publisher and editor of the "Gloucester Journal," and in 1781 hired rooms for Sunday schools, employed poor women at a shilling a day to teach, and induced large numbers of the poor children whom he found in the streets of the town to attend. In a short time Sunday schools were established in all the larger towns of England.

RAIL, the proper name of the *rallinæ*, a subfamily of wading birds of the family *rallidæ*. The genus *rallus* (Linn.) is characterized by a bill longer than the head, nearly straight and slender, with the culmen a little curved, and tip obtuse and slightly notched; nostrils in a membranous groove which extends for two thirds of the bill; wings short, with the second and third quills equal and longest; tail short and rounded; tarsi shorter than the middle toe, covered with transverse scales; toes long and slender, free at the base, the hind one short; claws short and sharp; forehead, as in all the subfamily, feathered to base of bill, the culmen parting the frontal feathers for a short distance and in an angle. There are about 20 species, found in all the temperate parts of the globe, resembling each other in habits and much alike in plumage; they inhabit marshes and borders of rivers, among reeds and aquatic plants, which their long toes, sharp claws, and compressed bodies enable them to climb and run over or between with great facility; the flight is awkward and slow, with the legs hanging down, and for short distances only except during migration; they are good swimmers and divers, and very rapid runners. Their food consists of worms, slugs, crustaceans, tadpoles, insects, and leaves and seeds of water plants; the nest is made of

coarse grasses, and placed in retired marshes, and the eggs are 10 to 12. They are very generally called marsh hens, as they resemble domestic fowls in their manner of carrying the head, in some of their habits, and in their cackling notes. The largest of the North Ameri-

Fresh-water Marsh Hen (*Rallus elegans*).

can rails, and one of the handsomest of the genus, is the red-breasted rail or the fresh-water marsh hen (*R. elegans*, Aud.); it is about 18 in. long, the bill 3, and 24 in alar extent, with a weight of about 1½ lb.; the color above is olive brown, with longitudinal stripes of brownish black, especially on the back; throat and lower lid white; neck before and breast rufous chestnut; sides, lower parts, and under tail coverts with transverse bands of brownish black and white; upper wing coverts reddish chestnut, the under black with white lines. It is found in the middle and southern states on the Atlantic coast, probably extending across to the Pacific, and chiefly on the margin of fresh waters; it begins to breed in the southern states about the middle of April in its favorite marshes; the young leave the nest as soon as born. The females are like the males, but smaller; they do not take to the water willingly, and are rather poor divers; the flesh is good, especially in autumn, and their eggs are said to be delicious. The clapper rail or salt-water marsh hen (*R. crepitans*, Gmel.) is about 14 in. long, with an alar extent of 20; the adult plumage is considerably like that of the last species, but the upper parts have a light ashy olive tint, and the neck and breast are more yellowish. It is abundant from New Jersey to Florida, extending also to South America, and is rarely found far from the sea; the nest is deep and funnel-shaped, made of marsh plants and fastened to reeds above the ordinary high tide level; incubation lasts 14 days; the eggs are collected by hundreds in New Jersey toward the end of spring. It is

not a rapid swimmer, but is a good diver, and a very swift runner either on the ground or on floating weeds; its flight is slow and generally straight; though esteemed as food, other species are more sought after, especially the sora, in the middle states. The Virginia rail (*R. Virginianus*, Linn.) is about 10 in. long, with an alar extent of 14; it is like the others in form, and resembles *R. elegans* in color, hardly differing from it except in size. It is found throughout the temperate regions of North America from the Atlantic to the Pacific, most abundantly along the margins of rivers and bays on the Atlantic, migrating south in autumn; it is a very rapid runner and good swimmer, feeding both on salt marshes and fresh meadows by day and night. It breeds from the beginning of March to the middle of June, according to latitude; like the other species it is a good ventriloquist, and seems often to be far off when close at hand; the flesh is good eating in autumn and winter. The European water rail (*R. aquaticus*, Linn.) is fulvous brown spotted with black above, bluish ash below, and barred black and white on the sides. The habits are the same as in other species; the flesh is esteemed, though having rather a marshy flavor.—The genus *ortygometra* (Linn.) has been subdivided into *porzana* (Vieill.) and *crex* (Bechst.). In *porzana* the bill is shorter than the head, the primaries longer than the tertiaries, the tail short, and the legs robust; there are about 20 species in the temperate regions of the globe, with habits similar to those of *rallus*. Among the North American species is the Carolina or sora rail (*P. Carolina*, Cab.), so well known and so abundant as to

Carolina Rail (*Porzana Carolinensis*).

be called "the rail" in the middle states; the length is about 9 in. and the alar extent 14; the color is greenish brown above, with longitudinal lines of black; behind the eyes, sides of neck, and breast bluish ashy, with round white spots on the latter; middle of abdomen

white. It occurs throughout temperate North America on both shores, migrating southward in winter; it is rarely seen east of New York; in autumn it is abundant in the rice fields and fresh-water marshes of South Carolina. It is semi nocturnal; when migrating the flight is low and in compact flocks; instinct teaches them the last moment at which they can remain in autumn, all migrating in a single day or night, whence the once prevalent idea that they dived under the mud to pass the winter. The little black rail (*P. Jamaicensis*, Cab.) is about 6 in. long, the smallest of the North American species of the family; the head and lower parts are slate-colored, nearly black on the top of the head; abdomen banded with white; upper parts brownish black with white stripes, and reddish chestnut on the upper back; the young are wholly bluish black. It is rare on the continent, but more abundant in the West Indies; it is highly prized by collectors. The yellow-breasted rail (*P. Noveboracensis*, Cab.) is about 7 in. long and 13 in alar extent; the color is ochre-yellow above, with brownish black and white stripes; neck and breast tinged with reddish, middle of abdomen white, sides banded with reddish brown and white; under tail coverts rufous, white-spotted, and under wing coverts white. It is found, though not abundantly, in damp meadows in the eastern and southern states; it approaches in habit the corn crane and in some respects the European quail, and was regarded by Audubon as one of the connecting links between land and water birds; the flesh is delicate.—In the genus *crex* (Bechst.) the bill is conical, shorter than the head, and the appearance and habits are like those of gallinaceous birds. (See **CRANE**.)

RAILROAD, or Railway, a road with wooden, stone, or iron sleepers supporting timber or iron ways upon which the wheels of carriages may run. The graduated earthen or stone embankment or cut which supports the road is called the road bed, while the sleepers, rails, &c., constitute the superstructure. Various devices have been employed since wheeled carriages were first used for facilitating their movements, but until modern times these have mostly consisted of levelling and hardening common roads. (See **ROAD**.) Wooden rails were first used as early as 1672 in a short road constructed by Mr. Beaumont at the collieries near Newcastle-upon-Tyne. They were laid exactly straight and parallel, and four-wheeled carts were drawn by horses upon them. Iron rails were first used at Whitehaven, England, in 1738; another iron railway was laid down by John Curr near Sheffield in 1776, but this was torn up by the colliers. In 1786 the first considerable iron railway was built at the iron works of Colebrookdale, and had its origin partly in the low price of pig iron. The upper rails were made of cast iron, 5 ft. long, 4 in. wide, and $1\frac{1}{4}$ in. thick, with holes through which they were spiked to the lower wooden rails or ground-sills; they were cast with a raised lip on the

outer edge to keep the carriage wheels upon the track. The success of this improvement led to its general use in and about mines and collieries, and for many years rails were made altogether of cast iron. These roads were called tramways, and were commonly built as follows: The road bed was brought to as uniform an inclination and level a surface as practicable; squared logs called sleepers or ties about 6 ft. long, 6 or 8 in. wide, and 4 or 5 in. thick, were laid crosswise, 2 or 3 ft. apart; upon these long wooden rails 6 or 7 in. wide and 5 in. thick were notched and pinned, 4 ft. apart and parallel with each other. The iron plates or rails were then spiked to the wooden rails, and the road bed was filled in with gravel, ashes, or coal waste, to form a smooth surface for the horses to walk upon. This is substantially the plan upon which railroads for collieries, quarries, mines, and streets are constructed at the present time. The first iron railway sanctioned by parliament, except a few built by canal companies to bring in the products of adjacent mines, was the Surrey railway, running from the banks of the Thames at Wandsworth to Croydon, which was authorized in 1801. From this time forward the principal improvements in railway construction related to the perfection of the form and materials of the rails and the method of fastening them, and later to the introduction and improvement of steam locomotives and machinery. Cast-iron rails had been laid by Jessop at Loughborough in 1789, without lip or raised edge, but having a smooth upper surface, upon which the carriages were kept by means of flanges on the wheels; these were called "edge rails," and were set in cast-iron chairs, which rested upon the wooden sleepers. Edge rails of oval section, with the longer axes vertical, were again used in 1801 at the slate quarries of Lord Penrhyn; they were $4\frac{1}{2}$ ft. long, and each end terminated by a pyramidal or wedge-shaped block, which rested upon and fitted into an iron sill. The carriage wheels were hollowed out to fit upon the convex surface of the rails, but as this device increased the friction by increasing the bearing surfaces, the surfaces of both rails and wheels were afterward made flat, and the wheels were made with flanges to keep them on the rails. By the use of these improvements it was found that one horse could do the work of 40 on a common road; they were rapidly adopted by the colliers, and in the north of England still further improvements were made in the form of the rails, with the view of increasing their strength without decreasing their weight. They were made still thinner, the oval cross section verging toward the pear shape, with the thicker part at the top, while the longitudinal section was straight on the top and curved downward on the bottom, the greatest depth of the rails being midway between the ends; those of this form were known as "fish-bellied" rails, and were used for some years after the introduction

of wrought-iron rails. This took place in 1808, though it was not till 1820 that suitable machinery was devised for rolling rails into other than flat shapes. This was a most important step, as cast-iron rails could not be made straight in greater lengths than 4 or 5 ft., and consequently required many cross ties and joints; whereas the introduction of wrought iron permitted the increase of the length of the rails by successive steps, till with the perfected processes of the present day they are made of iron and steel 30 ft. and even longer if required. With the improvements in the machinery for rolling rails, it became possible to make the new and improved forms of rails rendered necessary by the substitution of steam carriages for horses, which had hitherto been almost exclusively used. The force of gravity was utilized in exceptional instances where the roads sloped gradually from the collieries, and by the adaptation of ropes and wheels or windlasses the descending loaded cars were made to draw up the empty ones.—

Watt suggested the possibility of constructing steam carriages in 1759, and patented one in 1784. Oliver Evans of Philadelphia patented a steam wagon in 1782, the drawings and specifications of which were sent to England in 1787, and again in 1794-'5. In 1784 Murdoch, Watt's assistant, constructed a working model of Watt's carriage. In 1802 Trevithick and Vivian patented a high-pressure locomotive engine, and in 1804 built one for the Merthyr-Tydfil railway in S. Wales, which was found to work well with light loads upon a level surface or moderate grades, but if more severely tasked the wheels would slip without advancing. A check was thus put upon their use until some method could be devised by which they might obtain a hold upon the track or otherwise push themselves forward. A rack laid along the side of the rail, into which worked a toothed wheel fitted to the locomotive, was tried in 1811 on a colliery line near Leeds, but the friction was too great, and it was abandoned. The next year engines were tried with eight driving wheels for securing the required adhesion; and about the same time other engines were constructed with levers projecting behind and working alternately like the hind legs of a horse. In 1814 and 1815 engines with plain wheels were found to work successfully on some of the northern roads; but no other application was made of them than for transporting the coal and ore wagons of the mines. In 1814 George Stephenson constructed his first locomotive, which travelled at the rate of 6 m. an hour; in 1826 Seguin, a French engineer, built locomotives in which he increased the evaporative power of the engine by small tubes passing from the fire box to the chimney; in 1829 Stephenson and Booth built the engine Rocket, weighing 4 tons 5 cwt., which travelled at a rate of 35 m. an hour; in 1834 the Firefly drew a loaded train at the rate of 20 m. an hour; in 1839 the North

Star moved with a velocity of 37 m. an hour; and at the present time locomotives have attained a speed of 75 m., and for short distances even greater velocities have been reached. (See STEAM CARRIAGE.)—The first railroad for carrying passengers was the Stockton and Dar-

First Railroad Passenger Car.

lington road, built by Edward Pease and George Stephenson, and opened Sept. 27, 1825. The Liverpool and Manchester road, commenced in 1826, and opened Sept. 15, 1830, was intended by its proprietors to carry passengers at a high speed. As it would be expensive to do this with horses, it was thought that stationary steam engines placed at short intervals along the road might be used for the purpose of drawing the trains; but the success of the locomotives built by Stephenson, Ericsson, and others, under the stimulus of a premium of £500 offered by the railway company, caused this plan to be abandoned, and gave rise to the establishment of a new system of locomotion of almost limitless speed and capacity. The small engines at first used were soon found inadequate to the service demanded of them, and were replaced by others of larger size and greater weight; some now employed have 10 or 12 wheels and weigh in some cases as much as 75 tons, and there are many in all parts of the world weighing 30, 40, and 50 tons, according to their pattern and uses. Finally, owing to the great weight and high speed of these locomotives, and the consequent wear and tear upon themselves and the rails, joints, and bridges, it has come to be a grave question as to whether they have not grown beyond the limit of economy, and should not therefore be reduced in size and weight. The gauge of the Liverpool and Manchester railway was fixed by Stephenson at 4 ft. 8½ in., that being about the common gauge of the ordinary road wagons of the day. It was afterward generally adopted throughout the world, partly for the same reason that influenced Stephenson, but mostly because the English were the first locomotive builders for foreign countries, and stoutly adhered to the precedent set them by their most distinguished engineer. Later the merit of this precedent was disputed by Brunel and other able engineers, who claimed that a broader

gauge would give greater speed, safety, and economy; and roads of 5 ft., 5 ft. 5 in., 6 ft., and even of 7 ft. gauge were built. But the wider gauges are gradually losing favor, and have generally been abandoned for the 4 ft. 8½ in. (or the 4 ft. 9 in.), now commonly called the standard gauge. It has come to be contended by many engineers, and notably by Mr. Fairlie of England, that even the standard gauge is too wide, and that gauges of 3 ft. and less are still more economical. The success of the Liverpool and Manchester railway led to the projection of new roads in England, chiefly in the northern part, connecting together its principal cities; but the capacity of the locomotive was not yet fully developed or appreciated, and upon most of the roads it was considered necessary to overcome the heavier grades by the use of stationary engines. These and also inclined planes were gradually dispensed with, and tunnels were substituted for the purpose of reducing the grades and curvature, both of which were brought to a minimum by the expenditure of large sums of money. As a measure of safety, the most important roads in England were from the first built with double tracks; but this practice was not followed in America till the traffic on the various lines had become so great as to render it absolutely necessary.—The first railroad constructed in America was projected by Gridley Bryant, a civil engineer, in 1825, and carried through by himself and Col. T. H. Perkins in 1826. It was designed to carry granite from the quarries of Quincy, Mass., to the nearest tide water, and is known as the Quincy railroad. It is 4 m. long including branches, and its first cost was \$50,000. It was laid to a 5 ft. gauge, and was constructed as follows: Stone sleepers were laid across the track 8 ft. apart; upon these wooden rails 6 in. thick and 12 in. high were placed; upon the top of these rails wrought-iron plates 3 in. wide and ½ in. thick were spiked, but at all the crossings of the public road and driftways stone rails were used, and as the wooden rails decayed they were replaced by others of stone. This road was supplied with the first turn-table ever used, which was designed by Bryant and is said to be still in good order. Bryant also invented the portable derrick and the switch or turnout, and constructed the first eight-wheeled car ever used, by combining two four-wheeled trucks for hauling long pieces of granite intended for columns; and although a more complete application of the principle was afterward made by Ross Winans of Baltimore in the construction of eight-wheeled cars used on the Baltimore and Ohio railroad, the latter was unable to sustain his patent by law against the claims of others in Bryant's behalf. Winans began his experiments in 1830, with the view of designing a carriage which would easily traverse the short curves of the railroads then under construction, and ultimately produced the eight-wheeled or double bogie carriage, which is now

in use throughout the United States and Canada, and is being introduced upon the Pullman carriages into Europe. The second American railroad was laid out in January, 1827, and opened in May of the same year from the coal mines of Mauch Chunk, Pa., to the Lehigh river, and with turnouts and branches was 13 m. long. This was also of 5 ft. gauge, with timber sleepers and rails, strapped with flat iron. It was operated by gravity, though the length of the road was so great that mules had to be used for returning the empty cars to the mines. The Delaware and Hudson canal company sent Horatio Allen to Europe in 1827 to buy three locomotives and the iron for a railroad, which they built the next year from the coal mines at Honesdale to the terminus of their canal. One of the locomotives, built by George Stephenson at Newcastle-upon-Tyne, arrived at New York in the spring of 1829. Another, built by Foster, Rastrick and co. of Stourbridge, arrived shortly afterward, and went upon the railroad in the latter part of the summer. This was the first locomotive actually put into use in America. It had four wheels, a multitubular boiler, and the exhaust steam blast. In March, 1827, the legislature of Maryland granted a charter, modelled upon the old turnpike charters, to the first railroad company in America authorized to carry on the general business of transportation; its capital stock was \$500,000, with permission for its increase, and both the state of Maryland and the city of Baltimore were authorized to subscribe to its shares. In the beginning no one dreamed of using steam upon the road; horses were to do the work, and even after the road was completed to Frederick relays of horses moved the cars from place to place. From this circumstance the Relay House, at the junction of the main line and the Washington branch, took its name. This great highway, now known as the Baltimore and Ohio railroad, was begun July 4, 1828, and was gradually extended along the valley of the Patapsco 13 m. to Ellicott's Mills, thence to the Potomac at the Point of Rocks, thence along the valley of the Potomac to the Cumberland coal region, and finally across the Blue Ridge and Alleghany mountains to the Ohio river at Wheeling, with a branch toward Parkersburg in the direction of Cincinnati. At Wheeling and Parkersburg it now connects with other railroads owned or controlled by the same company, leading to Cincinnati and St. Louis, and also to Pittsburgh, Cleveland, and Chicago. In 1830 a small locomotive was built in Baltimore by Peter Cooper (now of New York), who was satisfied that steam engines might be adapted to the curved roads which would have to be built in America. He also believed that the crank could be dispensed with in the change from a reciprocating to a rotary motion, and designed his engine to demonstrate both conclusions. The boiler, which stood upright, was not so large as the ordinary boiler attached to the range of a modern man-

sion; the cylinder was $3\frac{1}{2}$ in. in diameter, and connected with the wheels by a system of gearing. The whole engine could not have weighed over a ton, but with it he drew an open car filled with the directors of the road and some friends, at a speed which reached 18 m. an hour, from Baltimore to Ellicott's Mills. This was the first locomotive for railroad purposes ever built in America, and the first one used in the transportation of passengers on this side of the Atlantic. This railroad was originally built with stone and wooden cross ties, and wooden rails strapped with flat bars of iron $\frac{1}{2}$ and $\frac{5}{8}$ in. thick, and from $2\frac{1}{2}$ to $4\frac{1}{4}$ in. wide. The bars were fastened down by spikes, the heads of which were countersunk into the iron. This method was generally adopted upon the early American railroads, but was soon found to be defective and dangerous. The oscillation and balloting of the engines and cars caused the ends of the rails to work loose, thus making what came to be known as "snake heads," and these were caught up by the wheels and thrust upward through the bottom of the cars. The successful use of locomotives in Europe and America gave an extraordinary impulse to the construction of new lines of railroad upon the principal routes of intercommunication. Charters for railroads were obtained in Massachusetts, New York, New Jersey, Pennsylvania, Maryland, and other states. Operations were begun in South Carolina in 1829 upon a railroad designed to connect Charleston with the Savannah river, six miles of which were completed and opened in the same year. The company having this work in charge, under the advice of their engineer, Horatio Allen, who had gone to England to examine the railways of that country, determined to operate their road by the exclusive use of locomotives, and offered a premium of \$500 for the best plan of horse locomotive. This was awarded to C. E. Detmold, civil engineer (now of New York), who designed and constructed an engine run by a horse walking on an endless platform, which carried passengers at the rate of 12 m. an hour. The same gentleman in the winter of 1829-'30 made the drawings of the steam locomotive *Best Friend*, designed by E. L. Miller of Charleston, which was built by the Kembles of New York and placed on the Charleston railroad late in the summer of 1835. This railroad was the first to use the important arrangement of two four-wheeled trucks or bogies for engines and passenger cars. As before stated, this arrangement was practically wrought out by Bryant on the Quincy railroad in hauling large masses of granite, and was experimented upon and finally in 1834 patented by Ross Winans, but seems to have been first put into efficient use in accordance with designs made by Horatio Allen in 1830. The eight-wheeled double bogie carriage was first used upon the Baltimore and Ohio road in 1834, and was built from the designs of Winans. In August, 1830, the Mohawk and Hud-

son railroad, from Albany to Schenectady, was begun; in October, 1831, it was carrying 387 passengers a day; and in 1832 a locomotive with a load of eight tons travelled on it at the rate of 30 m. an hour. Various railroads in the Pennsylvania coal region and the Baltimore and Susquehanna railroad were begun in 1830. The railroad from Richmond to the coal mines, 13 m. distant, was finished in 1831; and on April 16 of the same year the New Orleans and Pontchartrain railroad, $4\frac{1}{2}$ m. long, was opened. From this time forth railroads were multiplied with great rapidity. In 1832 it is stated that 67 were in operation in Pennsylvania alone; and in that year several of the most important railroads in Massachusetts and New Jersey were begun. Indeed, so great was the enterprise throughout the United States from 1832 to 1837 in the projection and construction of railroads, that at the end of that period the completed lines exceeded in number and aggregate length those of any other country. Since then, with occasional interruptions arising from financial crises and the civil war, the multiplication of railroads has kept pace with the extraordinary increase of population and wealth; and now the mileage of railroads in this country is more than four times as great as in Great Britain, and far in excess of that of all the rest of the world. The American railroads have however grown up under the requirements of the various regions, and have been planned, constructed, and fostered in a great measure independently of each other and without regard to any great or national system. The charters in nearly every instance were granted by the respective states for the roads in their own territory, so that most of the through lines connecting the great cities and widely separated regions of the country grew up by the consolidation of various short sections of road into continuous lines under one management, or by the longer and more prosperous roads leasing the shorter and poorer ones, and only occasionally by agreement of connecting roads to coöperate with each other in the arrangement of their trains. To the absence of national control over the construction of railroads is due the fact that no uniform gauge for the American system was adopted. Every state, and in fact nearly every company, was left free to fix its own gauge and decide upon the character of its own roads. The gauge of 4 ft. $8\frac{1}{2}$ in. first used in English locomotives was generally continued for the sake of convenience even after the locomotives came to be exclusively built in this country, but independent gauges were also introduced. The Ohio and New Jersey railroads generally adopted 4 ft. 10 in., which in connecting with the roads of the standard gauge necessitated the use of cars with the trucks adjusted to the narrower gauge, but having wheels sufficiently wide to run upon the wider gauge. These were called "broad tread" wheels, and the cars "compro-

mise cars." The railroads of the southern states, with only a few exceptions, were laid to a 5 ft. gauge; two in Ohio to 5 ft. 4 in.; several in Maine, Missouri, and Canada to 5 ft. 6 in.; while the Erie, the Atlantic and Great Western, and the Ohio and Mississippi were laid to the 6 ft. or "broad gauge." The last named road changed to the gauge of 4 ft. 9 in. in 1870, the work of moving in both rails having been completed in a single Sunday without the stoppage of trains or the slightest derangement of business.—Notwithstanding the original absence of system and national control, many important continuous lines have been developed by the consolidation of independent ones, and the construction of others necessary to connect or extend the various parts of the trunk lines. The first great lines of this character originated in the desire of the great seaboard cities to secure a larger share of the business from the interior and western states. The railroad from Boston to Albany, the New York Central, the Erie, the Pennsylvania Central with its eastern and western connections, and the Baltimore and Ohio, are the most notable instances illustrating the peculiar method by which the great trunk railroads have been created. The Atlantic and Great Western, the Toledo, Wabash, and Western, the Chicago and Northwestern, the Cleveland, Columbus, Cincinnati, and Indianapolis, the Michigan Central, and many others of equal or less extent, grew up in a similar manner. The money for carrying out these vast improvements was in general raised by private subscriptions to the share capital, supplemented by loans secured by mortgages upon the property created; in many instances, however, towns, cities, and even states subscribed to the capital stock, or lent their credit to the various companies. In 1848 the Mobile and Ohio railroad, designed to connect Mobile with the mouth of the Ohio river, was projected, and in the winter of 1849-'50 congress passed an act giving to that undertaking about 1,000,000 acres of the public lands lying contiguous to the route. This was the first act of the kind, and was soon followed by a grant of 2,595,000 acres to the state of Illinois, which conveyed it to the Illinois Central railroad company, for the purpose of aiding it to construct its road from Dunleith on the Mississippi river, in the N. W. corner of the state, to Cairo, 455 m., with a branch from Centralia to Chicago, 249 m. By the hypothecation and sale of these lands and the mortgage of its railroad, the company secured the means of completing its lines, and, with the exception of embarrassments during its earlier days and before the country along the road had become sufficiently developed to yield an adequate traffic for its support, this has been one of the most successful railroads of the country. The policy of granting public lands to railroad companies gave an extraordinary development to railroad enterprise in the northwestern, west-

ern, and southern states, which, aided by their great fertility and other natural resources, soon surpassed the older states in the length and number of their lines.—*Pacific Railroads.* The discovery of gold in California and the rapid increase of wealth and population in the territory west of the Rocky mountains, together with the desire of the older states to establish closer connections during the civil war with those outlying communities, caused congress in 1862 to authorize the construction of a railroad to the Pacific ocean, with various branches to connect it with rival towns on the Missouri river. This project was first brought into public notice by Mr. Asa Whitney, who from 1846 to 1850 advocated it in addresses to state legislatures and before public meetings, and memorialized congress on the subject. The idea was strongly advocated by Senator Breese of Illinois and by many other men of distinction both in and out of congress; but the plan first took tangible shape in the bill introduced by Senator Benton of Missouri, Feb. 7, 1849. In March, 1853, an act was passed providing for surveys by the corps of topographical engineers of the various routes, and particularly of a northern, southern, and middle one, with the view of determining which offered the greatest advantages for the construction of the railroad. These surveys resulted in the decision that the enterprise could be carried through upon either route which might be adopted; but owing to dissensions and rivalry between the northern and southern states, nothing further was done by congress till the war had removed this obstacle. Acts of congress were passed in July, 1862, and in July, 1864, providing for a subsidy in United States 6 per cent. gold bonds at the rate of \$16,000 per mile of railroad from the Missouri river to the base of the Rocky mountains, \$48,000 per mile for a distance of 300 m. through the mountains, \$32,000 per mile for that portion between the Rocky and Sierra Nevada mountains, and \$16,000 per mile for that west of the latter mountains. In addition to this subsidy, the same acts of congress gave to the railroad companies undertaking this great work 20 sections (12,800 acres) of land for each mile of railroad built, or about 25,000,000 acres in all. The first act of congress provided that the government subsidy of bonds should constitute a first lien upon the road and its appurtenances, but it was found that the money arising from the subsidy would not secure the completion of the work. Congress therefore released the first lien of the government, and empowered the railroad companies to issue their own bonds or debentures at the same rate per mile, and to secure their payment by a first mortgage upon their property. The railroad was built from the California end eastward by the Central Pacific railroad company, and from the Missouri river westward to the common meeting point at Ogden by the Union Pacific company. Work was commenced in 1863, but it was not till

824,821, or an average of about \$35,000 a mile, and this cannot have been far from correct. The cost of the Central Pacific railroad and branches, 1,222 m., in stock, bonds, and liabilities of every sort, was reported in 1874 at \$139,746,311, or an average of \$114,358 a mile. The Northern Pacific railroad company was chartered by congress in 1864, and subsidized, to construct a railroad from Lake Superior to Puget sound, 1,800 m., with a branch of 200 m. *via* the valley of the Columbia river to Portland, Oregon. The construction of the road was begun in 1870, but was arrested in 1873 by financial difficulties. In 1875 there were in operation 450 m. from Duluth, Minn., to Bismarck, Dakota, and 105 m. between Kalama and Tacoma in Washington territory. The Texas and Pacific railroad is to extend from Shreveport, La., and Texarkana, Ark., *via* El Paso, to San Diego, Cal., a distance from Shreveport of 1,514 m. In 1875 the main line was in operation from Shreveport to Dallas, Texas, 189 m.; also the division between Texarkana and Marshall on the main line, 75 m.—*Railway Statistics.* Details in regard to railroads are given in the articles on the various states and countries. The following tabulated statement from Poor's "Manual" shows the number of miles of road constructed in the United States each year since 1830:

YEAR.	Miles in opera- tion.	Annual increase, miles.	YEAR.	Miles in opera- tion.	Annual increase, miles.

The total mileage of railways in the United Kingdom has increased from 8,335 m. in 1855 to 13,289 in 1865, 15,376 in 1871, and 16,082 in 1873. Of the mileage in 1873, 11,369 m. were in England and Wales, 2,612 in Scotland, and 2,101 in Ireland. The authorized capital for the United Kingdom in 1873 was £676,686,586, of which £588,320,308 was paid in. The total receipts amounted to £57,742,000, including £31,821,529 from freight, £28,853,892 from passengers, and £2,066,579 from rents, tolls, &c. The working expenditures were £30,752,848, and the net receipts £26,989,152. In 1874 the Dominion of Canada had 4,099 m. of railway. The length of railways in operation in the chief countries of the European continent in or about 1872 was as follows:

—*Railroad Management.* The policy of governments and countries in respect to the construction of railroads at first differed as widely as the countries themselves, but now there may be said to be only two systems, the English and the French. In England and the United States the initiative is given by private enterprise, and the entire control of operations is exercised by joint-stock companies, through their officers or agents, subject only to the laws regulating and defining their powers. In France, Germany, Russia, and most countries of continental Europe, everything connected with railroads and other public works is organized on a systematic plan and conducted with complete uniformity. In England and America everything is left to experience, and no fixed practice or general principle exists. Government plays an insignifi-

cant part; when it has authorized the construction of a railroad and defined the powers of the company having it in hand, it goes no further. In France and most other countries the executive government determines the localities for which railway communication is to be provided, lays out the line, chooses the company which is to make the road, or if no company offers makes it itself, regulates the number of trains, fixes the tariffs, controls the administration, and in short attends to the minutest details of construction, maintenance, and operation. The point of principal importance in the comparison of the English and French railway systems is that, setting out with different policies—private enterprise and free competition on one side, state control and monopoly on the other side—both have ended in the division of the two countries among a few great companies, and the consequent triumph of monopolies. Starting from diametrically opposite principles, the two contrary systems have reached nearly similar results. The construction of railways as a whole has been as rapid in France as in England; their mileage is nearly equal, with not very different fares and nearly the same number of passengers and tons of freight per mile; while in the United States the mileage is nearly five times as great as in either France or England, though the aggregate cost of the railroads in each of the three countries is nearly equal. In America the tendency is toward amalgamation and monopoly. The richer companies are gradually absorbing the weaker ones, and yet so far the general result has been to cheapen transportation and give the public greater and better facilities. In some instances consolidations have taken place to such an extent that the public has become alarmed, and efforts have been made, especially in Massachusetts, Wisconsin, and Illinois, through the agency of boards of railroad commissioners, to exercise such control over the railroad system of the respective states as to properly harmonize the interests of the public and the companies. Many of the state legislatures have undertaken to equalize and control the fares and rates of freight by arbitrary enactments, while others have endeavored to do so through their boards of commissioners. As yet no practical settlement of the various questions has been reached. The railroad companies make the general claim that their charters are contracts with the state, which authorize them to regulate their own charges and control their own business, and which cannot be altered or amended directly or indirectly without their consent; and finally that all efforts to do so are in contravention of the constitution of the United States, which prohibits the states from making laws impairing the obligation of contracts. The theory of those who assert that the states have the right to regulate the rates at which passengers and freights shall be carried by railroads, is that they are public highways, controlled by

corporations created by law, and therefore subject to the law-making power whenever it may choose to intervene. Still another theory has been set up and received public attention, namely, that the authority to regulate commerce between the states, given to congress by the constitution of the United States, is broad enough to cover and does cover the right to regulate and control the railroads in all matters pertaining to their operation, and particularly in fixing the rates at which freights and passengers shall be carried, notwithstanding the fact that railroads for commercial purposes were at the time of the formation of the constitution entirely unknown and unthought of. What will be the future solution of this question, now receiving the attention of many writers and thinkers in all parts of the world, cannot be predicted. In France and other countries, where a system of monopolies was deliberately established by the government, a system of checks has been or can be established in the interest of the public. In England the purchase of the railways by the state has been urged by an influential party, on the ground that the state is the only power which can properly control an interest so great and which so vitally affects the welfare of the entire nation; and in Belgium such purchase is gradually being made by the government. From the peculiar nature of our institutions, as well as from the complexity and extent of our railroad system, the regulation of railroads by government is much more difficult, and therefore probably much more remote, than it is in Europe. On the other hand, the difficulty of consolidation and combination, owing to the extent of the country and the diversity of interests, is also greater, while the danger of monopolies is less; and hence the question will probably receive a solution in America founded upon competition.—*Construction and Rolling Stock.* Before deciding upon the construction of a railroad along a given route, a careful calculation of the amount of transporting business already done on the route should be made, with the view of ascertaining whether it is sufficient to justify the proposed railroad; though estimates of this kind have in general been found to afford a very uncertain indication of the amount of business which the railroad itself when constructed would obtain. A more enlarged estimate should be made of the extent of country tributary to the proposed railroad, together with its mineral and agricultural resources, developed and undeveloped, its wealth and population, and also the influence of the new route of transportation upon those already established, as well as upon the habits and productions of the people who are expected to use it. The first question to be considered is, Will any kind of railroad pay when built? the second is, What kind of a railroad, all things considered, should be built? and the third is, Where and how can the money be got to pay

for it? In one region a double track steel railway, with low grades, slight curvature, iron bridges, brick or stone station houses, and the largest and best rolling stock, all costing \$100,000 more or less per mile, may be necessary to accommodate the business; in another case, a single track, with heavier grades and sharper curvature, wooden bridges, and cheaper appurtenances of every kind, may be sufficient; and in still another case lighter rails, narrower gauge, and still lighter rolling stock and machinery, may prove to be more than is required. No rule can be given for telling beforehand just what kind of a railroad should be built, or, when built, will prove to be the one best suited to the situation. Such questions are necessarily indeterminate. It is however a safe principle, economically considered, that no more expensive railroad should be built over any route than can be paid for out of the money which the people to be benefited by it will subscribe to the company's stock or lend upon the pledge of its mortgage bonds. This rule has not generally been kept in view in the United States and other new countries, and the consequence is that there has been a great over production of railroads at various periods, and particularly between 1863 and 1873. To such an extent has this over production gone that the financial panic of October, 1873, has been attributed by some writers exclusively to this cause.—Preparatory to the construction of a railroad, surveys are made along the several routes the road may follow, and plans are constructed representing the exact distances and grades or the amount of deviation from a level at all the points. From these plans the amount of excavation and embankment, of tunnelling, bridging, &c., necessary to bring the road within the required degree of straightness and level, are calculated. Thus the estimates are obtained, by comparison of which, including also the ascertained amount to be paid for right of way, the construction of the road is determined. The importance of the road and the special purpose for which it is designed are to be duly considered in deciding upon saving of distance and reduction of grades by heavier expenditures. Roads upon which numerous trains are to pass daily, each one of which will incur a certain additional expense for every additional mile, and each mile will involve a certain annual expense for keeping in repair, may economically be shortened by increased outlays that would be entirely inadmissible in securing a similar reduction of distance for less travelled routes. So upon roads that are to be run at high rates of speed short curves must be avoided at any expense. It has happened, from the experience gained in the working of railroads, that some of the earlier lines have been economically reconstructed by a partial abandonment of the old routes under more judicious surveys, or from the increase in the business justifying the adoption of a more perfect line. As already

remarked, the old system of occasional inclined planes is almost wholly abandoned for roads of general travel, and the construction and capacity of locomotives and carriages are so much better understood, that a much greater range in curvatures and grades is now found practicable than was formerly ever thought of. As regards curves, it was at first recommended in England to fix the minimum radius that should be allowed at one mile, and in 1846 it was one of the "standing orders" of parliament that no curve should be made with a radius of less than half a mile (2,640 ft.) without special permission of parliament. In France a minimum was established by "the administration of roads and bridges" of 2,700 ft., or about 2° . On the Hudson River railroad the minimum curve has a radius of 2,062 ft. $= 2.75^\circ$. But the Baltimore and Ohio road was built with several curves of 400 ft. radius (14.25°), and with one of 318 ft. (18°), and no difficulty was experienced in running over them at 15 m. an hour. The narrow-gauge railroads now coming into favor for light traffic, in thinly settled or mountainous districts, are built with curves of very much shorter radius, in some instances not exceeding 50 ft. in length. The objectionable features of the curves are avoided by making the wheels conical, of greater diameter within than at their outer edge; the effect of this in running on a curve, when the wheels on the outer side are pushed by the centrifugal force outwardly, is to make them roll on their larger diameter, and at the same time the wheels on the other side, drawn in toward the centre of the track, roll on their smaller diameter. On each side they are thus accommodated to the different lengths they have to traverse, without straining the axles and without greatly increased friction or slipping of the inner wheel upon the rail. The friction against the outer rail due to the centrifugal force is partially prevented by elevating the outer rail. The object of attaching the wheels to their axles, instead of letting them turn upon these, is to secure greater steadiness at high speed. The requiring of minimum degrees of curvature has been abandoned upon the English and French roads. In France, upon the Paris and Orsay and Paris and Sceaux railroads, there are curves of 82 ft. radius, and trains, the engines and carriages of which are provided with loose wheels and guide rollers, run through complete semicircles at 20 m. an hour.—Upon the earlier roads in Great Britain and in the United States grades of 30 or 40 ft. to the mile were considered heavy, at the last figure nearly tripling the power that was required to draw the load upon a level. Grades of 70 to 80 ft. were regarded as almost impracticable, as they would compel the carrying of light loads over the whole line, and therefore, when such grades could not be otherwise avoided, inclined planes worked by stationary engines were adopted. The Hudson and Mohawk railroad, in a length of 16 m., was built with one such plane at

Albany, and another at Schenectady. The Philadelphia and Columbia railroad was also built with two planes, one at Columbia and the other near Philadelphia, and there were ten on the Alleghany Portage road over the Alleghany mountains, all of which have been displaced by the substitution of heavier grades on more extended lines. But as experience was acquired in the working of railroads, it was found that locomotives rarely carried maximum loads for the moderate grades, and that a temporary slackening of the speed upon the steep grades rendered a further portion of the power of the locomotive available for overcoming the increased resistance. Thus, when the doubtful point as to the adhesion of the driving wheels to the rails was satisfactorily determined, and the common law of mechanics, that power can be gained at the expense of motion, was found to be applicable to ascending grades of a railroad, these were increased much beyond their former limits. High grades were sooner introduced in this country than in Europe, but they have since been adopted there also. On the Mount Savage and George's Creek railroads in Maryland grades of 140 ft. to the mile have long been used; and on the Baltimore and Ohio road, through the Alleghany mountains, of 114 ft. In England those of 100 ft. to the mile are not uncommon, and there are several from 130 to 150 ft. At Sheffield is a grade of 196 ft. to the mile, and the same is seen at Oldham on the Lancashire and Yorkshire road, extending for $1\frac{1}{2}$ m. In France on the St. Germain railroad is a grade of 123 ft. to the mile for about $1\frac{1}{2}$ m.; and it is now asserted by engineers that grades of 370 ft. to the mile can be worked by locomotives, but that on heavy grades the locomotive should take no more cars in descending than in ascending.—The proper preparation of the road bed should be an object of the most particular care. Being the foundation and support of the whole superstructure, it should as a matter of economy be made as firm and durable as possible. But it is in this that the American roads are most defective. The least width of embankments for double tracks ought not to be less than the width of the two tracks, with 6 ft. between them, and 6 ft. outside of each. In excavations the width of ditches on each side should be added. A common width of embankments in England is 33 ft., while on the principal American roads it varies with the height of the embankment. The transverse slopes of the English roads are much flatter than ours, and are commonly well protected with a good grass sod. But the most essential difference is in the drainage, upon which more than anything else depends the durability of the earthwork and of the sleepers and rails. Upon some American roads the sleepers are laid directly upon the natural soil, or upon this thrown up in a bank. Where the ground freezes, any superstructure on such a basis is certain to be more or less displaced in

the spring thaws; in wet weather it must prove very insecure, and in dry weather very dusty. The sleepers soon settle irregularly, placing the rails out of line, and thus are involved rapid wear, deterioration, accidents, and loss to the rolling stock and to the road. The dust rises in clouds, to the great injury of the machinery and of the passenger cars, and seriously incommoding the passengers themselves. The effects of water about the earthwork of railroads are regarded as so injurious that an eminent English authority says: "Wherever it is known or suspected to exist, its immediate source should be traced, and every possible means adopted for diverting it from the slopes and adjacent surfaces." Not only are capacious and permanent culverts, ditches, and drains abundantly provided, but subdrainage by tile drains is also employed to great advantage; and as a final precaution the road bed is ballasted, usually a foot deep beneath the sleepers and another foot around and over them, and for a width on double tracks of 26 ft., the quantity per mile amounting to 10,000 or 12,000 cub. ft. The material preferred for ballast is gravel containing a natural mixture of clean sand, and next to this broken stone in pieces not exceeding $2\frac{1}{2}$ in. in diameter. Limestone is not so good as gneiss, as it packs too densely, and trap rock also is likely to become too solid and rigid. A certain elasticity in the bed is essential for the durability of the rails; and where no other suitable material is at hand, common clay burned in lumps in great heaps intermixed with bituminous coal has been found to answer very well, especially if hard-burned. Cinders and small coal are excellent materials, and in Holland shells and broken bricks are extensively used. The road bed through the long English tunnels, and also upon the viaducts, is well ballasted, and the wear of the rails is thereby materially decreased. The wooden sleepers on many European and some American roads are also protected by some chemical application. (See PRESERVATION OF WOOD.) The ordinary duration of sleepers upon American roads is hardly 7 years, but upon English roads it is 15 years and upward. By the scrupulous attention directed to these details in building the European roads a great saving is effected in the cost of "maintenance of way," engines, and working. Only one half as much fuel is consumed to the mile run on the English and French roads as on those of the northern United States; and the consumption of fuel may be taken as a measure of the resistances overcome. If the English trains are from 20 to 30 per cent. lighter than those of American lines, they are run 25 per cent. faster, thus requiring about the same power. —The superstructure of railroads is almost universally laid upon transverse wooden sleepers, the primary object of which is to give a steady bearing upon the road bed. Seasoned white oak is preferable to any other wood

for strength and for holding the spikes. Hemlock is better than chestnut, and both these are extensively used in the United States. Their dimensions are commonly 8 ft. long with 7, 8, or 9 in. width of bearing surface, and their distance apart from centre to centre is from 2 ft. $1\frac{1}{2}$ in., as on the Erie road, to 2 ft. 6 in. On the English roads they are commonly 9 ft. long, 10 in. wide, often squared, and 5 in. thick. They are usually laid 3 ft. apart from centre to centre; and that a uniform bearing may be secured, particular care is taken that the sleepers are alike in size and regularly spaced in their beds. In France the experiment has been tried of cutting the sleepers in two in the middle, leaving one in every 10 or 12 ft. to bind the two rails together. The result was very satisfactory, the object being to prevent the spring of the full-length sleepers or the movement they sometimes acquire on their centre. But for these and detached rectangular blocks of any material, either transverse or longitudinal, it is essential that the supports should be well packed upon a thoroughly ballasted road bed. In England and India, where wood is expensive and iron comparatively cheap, rectangular blocks and also inverted pots of cast iron have been tried upon some of the roads, and with good results; but the conditions of cost are altogether unfavorable to the adoption of such devices in the United States. Granite sleepers have been tried and have continued in use upon one of the tracks of the Boston and Lowell road. They make a very hard and rigid support, and cannot be used in connection with wooden sleepers interspersed or alternating with them, unevenness in the track soon resulting. The smooth face of a rock ledge has been tried upon the Manchester and Leeds road, the rails being spiked directly down upon it. It was soon found necessary to take them up on account of the excessive wear upon the rails thus placed. The Great Western road in England is constructed with longitudinal bearings or sills measuring 10 in. square, and framed together by cross ties of 6 by 4 in. every 6 ft. The arrangement is said to be easy on the rolling stock, but as regards cost of maintenance of way this is one of the most expensive roads in England.—The iron rails, which are generally straight bars of wrought iron, differ greatly in the shape of their cross section, their weight, quality, and the manner in which they are secured to the road bed. Almost the first form was the fish-bellied rail, made about the year 1820. This soon gave place to others of more economical shape, as the T and the π rails, and to these was added the bridge or hollow rail, the form of which is nearly that of the letter U inverted. These have been variously modified in their figures and proportions, and a great number of other forms that may not be referred to either of these have been introduced upon different roads. In the United States an inverted T rail has

been in very general use, so as to be known as the American rail. It has a broad bearing base, and is easily secured to the sleepers by hook-headed spikes driven into elongated slots in the edge of the flange, or merely over the edge, thus allowing expansion and contraction of the rail with changing temperatures without disturbing the fastenings. With this rail the cast-iron chairs employed for seating and holding almost all other rails were at first used to strengthen the joints. Up to about the year 1854 the weight of rails had been steadily increasing from about 35 lbs. per lineal yard till it had reached 85 and in some cases even 100 lbs. No advantage was found in the very heavy rails, however, but on the contrary the iron in such large piles was necessarily less worked in the manufacture and was in a poor condition for wear. The tendency has since been to return to lighter rails, of 55 to 65 lbs. to the yard, and to require these to be made of iron originally good, the piles to be first rolled into blooms, and these to be again brought to a welding heat, and then rolled into rails. The miserable quality of much of the iron on American roads is due to the deficient working, the fibres of the iron as it wears showing that they had never been thoroughly incorporated together. In bargaining for it no test and no particular conditions of manufacture were required, as is customary in other countries. Rails of 45 lbs. have worn under the heaviest traffic for 20 years, as those laid in 1837 on the Reading railroad, while others of nearly double the weight have given out on other roads in one, two, or three years. The first rails employed on the Stonington railroad, of 54 lbs. to the yard, also lasted 20 years. Rails have gradually increased in length to 15, 16, 18, and 20 ft., and even 30 ft., which latter is now the common length made by American rolling mills and used upon American railroads. An important feature in the rail is its height or depth. Its stiffness, if the rail could be regarded as a rectangular beam, increases as the square of the depth; thus doubling the height and retaining the same weight of material quadruples the stiffness, but doubling the height and weight also increases its stiffness eight times. The effect of a want of stiffness in the rail is deflection between the supports under the weight and a mashing of the iron into the wood of the sleepers, which continually increases the mischief. Even between rigid supports the temporary depression of the rail is such as to present a continual ascending plane in front of the wheels, which the descent of the slope from behind does not in any measure compensate, the advantage of this being wholly balanced by other considerations. In 1857 steel rails were first rolled in England, and so greatly were they found to surpass iron rails in endurance, that, notwithstanding their greater cost, the demand for them kept ahead of the capacity of the mills to make them, till Besse-

mer's process of producing them from the puddling furnace reduced their cost and greatly increased the demand for them. At first steel rails were used only at such points as were subjected to extraordinary usage, as at terminal stations and for switches, frogs, and crossings. They were gradually introduced by the roads having the heaviest traffic, and finally they have come to be used in the first construction of many of the more important new roads, and by nearly all the old ones instead of the iron rails as they wear out. The following figures show the sections of rails now commonly in use in America and England.—Various devices

Sections of Rails.

have been invented and used from time to time in securing rails to the sleepers, and for keeping their ends together. All of them recognize the effects of expansion and contraction of the rails under the action of the weather, and in laying rails a proper allowance, varying with the length of the rail and the variations of temperature, is always made for this. By neglect of this precaution the rails heated by the sun have sometimes expanded so as to be thrust upward, lifting the sleepers one or two feet out of the ground. From this cause, a train running in June, 1856, on the North-eastern railway in England, at 40 m. an hour, was thrown off the inside of a curve, though the 82 lb. rail was fastened every three feet in heavy chairs and "fished" at the joints. Almost the universal fastenings in England used to be cast-iron chairs, made to hold the rail in an opening in the top, into which it was seated and keyed by a wooden wedge. The chairs were themselves strongly bolted down upon the sleepers. Those for receiving the two ends of adjoining rails were much heavier and stronger than the others, weighing from 26 to 39 lbs., and others 18 to 26 lbs. It is of great consequence to keep the ends of the rails securely upon the same horizontal line. If one end is depressed by the weight coming upon it, the wheel strikes the end of the next rail with a concussion that soon shatters the rail, and being repeated at other joints seriously injures the rolling stock. Various methods of keying and fastening the ends of the rails have been used, but they have generally been discarded in favor of what is known as the fish joint, first tried in 1843 at New Castle, Del., but not finally adopted to any extent till 1847. This method was not favorably received on American roads at first, owing to the difficulty of applying it to the low rails generally in use, but in some form or other it has finally superseded all others everywhere. As first proposed, two sleepers were to be placed 6 in. apart at the joints, and

two plates of iron slightly wedging were to be driven one on each side between the jaws of the chairs flat against the sides of the two rails. Instead of this, however, a pair of iron or steel plates 18 in. long, $\frac{3}{4}$ in. thick, and about 3 in. wide, are bolted together through the rails with $\frac{3}{4}$ or $\frac{7}{8}$ in. bolts, the holes in the rail being elongated to allow for contraction and expansion. Another form of fish joint is constructed by applying the bars to the flange of the rails and bolting them firmly to a suspension plate extending under the joint from one rail to the other. Nearly all the forms of the fish joint will give a smooth track when first laid, but the natural tendency of the nuts holding the fish plates to the rails is to work loose and thus to weaken the joint. Various devices more or less efficient have been invented for locking the nut and thus insuring the stiffness of the joint. In order that trains of cars may pass from one track to another an extra pair of rails are laid down, which can be moved so as to complete the connection with either one of the lines as desired and break it with the other. These movable rails are called switch-
es, and are commonly controlled by a long bar under the surface connecting with an upright lever at the side of the road. This is in the care of the men known as switch tenders, whose duty it is to see before the approach of every train that the rails are so placed as to carry it upon the right track. Turn-tables are platforms constructed of wood or iron which can be pushed round upon a circular track sunk below the level of the ground. A locomotive or car being run on to the platform, it is thus easily turned about or directed upon any other diverging track, numbers of which usually concentrate around the turn-tables.—The passenger cars or carriages used upon railroads are generally constructed after either the English or American plan. The former had its origin in the old-fashioned stage coach, and in many instances preserves the outlines of the stage coach body on its sides. It is generally about 24 ft. long and divided into four compartments, each carrying six passengers. Each compartment is upholstered according to the class to which it belongs, and is furnished with two doors for ingress and egress, the upper parts of which are of glass. These compartments have no communication with each other, nor is there any means of passing from one carriage to another, except by the precarious means of a foot board running along the outside of the carriages. They are carried by four and sometimes six wheels, fastened rigidly together. The American passenger car, as before shown, had its origin in the sharp curves of

the American railroads, and was originally constructed by splicing two common English carriages together and placing a pair of bogie trucks under each end. At first these trucks were made with four wheels, but now they are frequently made with six and eight, the weight of the car being equally distributed over them by means of equalizing beams. The cars are from 46 to 60 ft. long, are entered by doors at the ends, and carry from 44 to 62 passengers. They are warmed by stoves or hot-water heaters, and are furnished with water and water closets, while the English carriages have none of these conveniences. The American cars were formerly coupled into trains by means of links and pins, but these together with the weak platforms connecting them were found to be the cause of many accidents. They have been replaced to a great degree by Miller's patent buffer, coupler, and platform, which couple the cars automatically, hold them together without motion, and in case of accident, the platform being strongly trussed, the danger of crushing or telescoping is entirely obviated. Sleeping cars were first adopted by a few of the leading American railroads about 1858, but they were for the most part crude and unsatisfactory in their arrangement and appointments. They were constructed under a variety of patents, employed various devices which had not yet been perfected by experience, were chiefly used for local travel, and did not leave the roads owning them. It soon became apparent that a class of cars that could be used both night and day, and run between distant points over several different roads, would be necessary to supply the growing want of the public. In 1864 George M. Pullman invented and patented a car designed to meet all the requirements of the problem, and so great was its success that it grew rapidly into popular

Pullman Parlor Car.

favor, and supplanted all others. In 1867 the Pullman palace car company was organized for the purpose of conducting the sleeping car business, now rapidly increasing in magnitude and importance. It contracts to furnish its

cars to railroad companies for a period of 15 years, giving each company the option, if exercised within a reasonable time, of purchasing a half interest in the cars assigned to its road, and of sharing equally with the Pullman company in the results of the business. The Pullman company furnishes the various kinds of cars required for the business, employs the servants and attendants, and maintains all the interior equipment pertaining to the sleeping accommodations. The railroad companies control the movements of the cars, carrying their passengers in them, receive the whole of the railroad fares, and maintain the outside and running gear of the cars, exactly as they do their own. Upward of 60 railroads in the United States, Canada, England, and Italy have entered into contracts with the Pullman company. Some of them are participants in the entire business, while others are joint owners with the Pullman company in the cars assigned to their respective lines. The present standard sleeping car exceeds the weight of the ordinary 12-wheeled first class passenger car used on the leading railroads by about $2\frac{1}{2}$ tons, the excess being due to the bedding and partitions essential to the sleeping arrangements. These cars are now used on more than 30,000 m. of railroad in America, and the advantages of the system have so recommended them that they have recently been adopted with favor in England and Italy, and will probably make their way at an early day to the railroads of the rest of Europe. The Pullman company has adopted a number of ingenious devices which very greatly increase the comfort, safety, and healthfulness, and decrease the fatigue, anxiety, and loss of time of railroad travelling. The freight cars or carriages used upon railroads are constructed according to two distinct systems, the English and American, which like the passenger cars differ especially in reference to the trucks, the former using the rigid four-wheel system, and the latter the bogie truck system. The American railroads use wheels of cast iron or low steel almost exclusively, the surfaces of which are hardened by chilling them in cooling; while all European roads use wheels of wrought iron, steel, and wood. The former are much cheaper, but said to be more liable to accident.—In treating upon railroads numerous important considerations present themselves besides those already noticed, each of which should receive particular attention. Such especially are the viaducts, bridges, and tunnels, and the immense cuts or excavations and embankments; also the processes employed by the engineers in laying out the road, their seeking for the most level and the straightest line while restricted by the amount of means provided, and planning the excavations and embankments, so that the material supplied by the former shall amount as near as may be to that required by the latter. The station houses, which in themselves are an important class of structures peculiar to this

new improvement, are generally constructed of brick or stone in Europe, of iron in tropical countries, and in America at first of wood, for which brick, stone, or iron is nearly always substituted as soon as the change can be afforded. Railroad bridges are generally built of iron and placed upon stone or iron supports in all countries except the United States, where engineers in the first construction of railroads more commonly use timber owing to its great abundance, lightness, and cheapness. Tunnels constitute a remarkable feature in the construction of railroads. In Great Britain, where it is considered to be more economical to tunnel through rock than to make open cuts deeper than 60 ft., many tunnels have been constructed, several of them over 3 m. long. The Mont Cenis tunnel through the Alps is nearly 8 m. long; the Hoosac tunnel in Massachusetts is nearly $4\frac{1}{2}$ m. long; and it is now proposed to construct one under the straits of Dover, 21 m. long, to connect the English and French railway systems. (See TUNNEL.)—*Cost of Railway Construction and Management.* The comparative economy in the construction and operation of railroads has received particular attention from many competent engineers and railroad managers. It is well known that the English roads have been built at an extraordinary amount of first cost, but it does not appear that the expenditures for actual construction have been much larger than in the United States for works of similar character. The practice in the two countries has been entirely different. In England the plan has been to build them in the most solid and substantial manner from the start, and to supply them with every appliance necessary for their operation; while in America the general rule has been to build upon the cheapest possible plans, with light rails, narrow banks, heavy gradients, wooden bridges, and less expensive cars, buildings, and machinery, and to depend upon future earnings for the means with which to bring the works up to the standard required by the increasing business of the line. Among the large items of cost upon English lines is that of land damage or right of way, the average of which has been rated at about \$45,000 a mile, or about the average cost of American railroads. The "parliamentary expenses," incurred in obtaining charters, are also very great, amounting in several instances to an average of \$7,345 a mile, and in the case of the Great Northern railway to an average of \$16,000 a mile. The several items of interest, discount on loans, bonuses, and commissions, also add greatly to the aggregate cost of railroads in all countries. Larger expenditures than are usual in the United States are involved from the more unfavorable physical features of the country, the topography presenting no long lines of watercourses nor wide table lands, both which are common in this country. Boggy districts are also more frequent in England, and the construction of a

permanent road across these has often cost immense sums. Even when the embankments through them have been apparently completed, as much more material has in some cases been required for their maintenance in consequence of their subsidence. The bridges, viaducts, tunnels, &c., are much more numerous and expensive structures upon English than American roads. The superior equipment of engines and carriages adds a considerable amount to cost per mile, some of the roads having even more than a locomotive for every mile, the cost of which averages about \$12,000 each. Among the heavier items of expense are the approaches to the cities, London particularly; where the roads for several miles are frequently constructed upon arched viaducts of brick. The London and Greenwich line, $3\frac{3}{4}$ m. long, thus built, cost \$1,299,651 a mile; the London and Blackwall, of the same character, \$1,406,304. From such causes the total cost of English roads has amounted to about \$170,000 a mile. The French double-track roads in 1857 were estimated to have cost \$101,877 a mile; about one fourth of the whole was for earth-work and "works of art," as bridges, viaducts, and tunnels; one quarter for rails, chairs, ties, and keys; and \$6,039 for ballast, much more even than upon the English roads. Few roads in the United States have reached an expenditure for construction equal to that of the least expensive roads of Great Britain; and the average cost of all those of the United States is estimated at little more than \$60,000 a mile.—The effect of the superior character of English railways is shown in a remarkable manner by the low rate per mile at which the permanent way is kept in order, and by the cheapness with which they are operated as compared with the same items for equal traffic on American lines. In Great Britain the distance run to a ton of bituminous coal or of coke varies from 75 to 118 m., the latter having been obtained with coke for a full year on the Cork and Bandon railway; 75 m. is considered to be a fair average. In America the number of miles run per ton of bituminous coal varies with the quality of the coal, weight of the trains, and gradients of the roads, from 35 to 60 m.; 45 m. may be considered as about a fair average. The rate at which trains are run upon the English roads is not so high as it was formerly. Passenger trains run from 18 to 40 m. an hour, the latter being the speed of some of the express trains; the average rate is about 27 m. Freight trains average about 15 m., including all stops. The highest rate for a passenger train attained for a few miles together has been 73 m. an hour. A speed of 60 m. is made daily for short distances, and sometimes even of 78 m. an hour. The average speed is considerably greater than on the French roads, and also exceeds that on the American, where it is not over 25 m. an hour, though 35 and even 40 m. are made upon some of the principal lines by the fastest trains.—According to the report of the Massa-

chusetts board of railroad commissioners for the year 1874, it appears that one passenger was killed and seven were wounded during the year by causes over which they had no control. The whole number of persons carried by rail during the year was reported at 42,480,000, and the average journey at 16 m.; it consequently follows "that the average journey by rail, resulting in death, during the last year, has been 679,000,000 m., and that resulting either in death or injury has been 85,000,000 m.; in other words, in estimating the chances of danger in travelling by rail in Massachusetts for any given person, the returns of the last year show that he will probably travel 85 millions of miles before sustaining any injury from an accident from causes beyond his control. The ordinary average of accidents of this description in Massachusetts, in years past, has been about one passenger to each 1,400,000 carried; during the past year it has been one only to each 5,300,000 carried, and for the previous year one to 42,400,000 carried." In contrast with this it is added that "through a period of ten years, 1859–'69, one passenger was killed or injured on the French railroads to each 674,000 carried, and in England the average has been about one in every 430,000; or, in the first case, twice the proportion* of Massachusetts casualties, and in the last, three times the proportion." The foregoing is a more favorable statement than can be made by the average of the American railroads, and yet it is believed that they in turn can show a greater degree of safety in the transportation of their passengers than obtains in either England or France.—*Narrow-gauge Railroads.* As before stated, the standard railway gauge of the world is now 4 ft. 8½ in. In 1832 a horse tramway, since known as the Festiniog railway, was built in Wales for the purpose of carrying slate from the quarries to Port Madoc. It was nominally of 2 ft. gauge, and was used as originally designed till 1863, when C. E. Spooner, the engineer of the line, recommended the use of locomotives. Seven of these were built, two weighing eight tons and five weighing ten tons each. In 1869 Mr. Fairlie built an engine for this road known as the Little Wonder. It is mounted on two trucks or bogies, each having four coupled wheels 2 ft. 4 in. in diameter with a wheel base of 5 ft., making the total wheel base of the engine 19 ft. The cylinders are $8\frac{3}{16}$ in. in diameter and 13 in. stroke, and the entire engine weighs 19½ tons. The success of the Festiniog railway and the Fairlie engines became widely known; and the writings of Mr. Fairlie, published in 1870 and 1871, on "The Gauge for the Railways of the Future," again attracted the attention of engineers throughout the world to the question of the gauges. The advocates of Fairlie's system claim: 1, that the cost of constructing, taking the average expense, will be found to vary as the gauge; 2, that every inch added to the width of the gauge beyond what is ab-

solutely necessary for the traffic adds to the cost of construction and increases the dead weight of the rolling stock and the cost of working; 3, that the dead weight of the trains is in direct proportion to the gauge on which they run; 4, that a saving in first construction equal in many cases to 33 per cent. can be made by the adoption of the narrow gauge, which allows greater curvature, narrower banks, and lighter bridging, rails, and ties; 5, that narrow-gauge railroads have relatively greater traffic capacity than roads of the standard gauge; and finally, that they are safer and can be more economically maintained and operated. Narrow-gauge railroads have been built in many parts of the world. At the end of 1874 there were 2,025 m. in operation in the United States, 511 m. under construction, and about 6,000 m. more projected; and in Canada 594 m. were in operation and 886 m. projected. The gauge of these roads is generally 3 ft., though that of the East Indian roads is 3 ft. 3½ in. or one metre, and a few in other countries are 3 ft. 6 in. The rails weigh from 24 to 52 lbs. per lineal yard. The engines, rolling stock, and other appurtenances are generally built after the same plans used by the roads of the standard gauge, but proportionally smaller. — *City Railroads.* Although railroads were long used in Great Britain with horse power only, this method of working them was there generally abandoned; but in the United States their peculiar adaptation for the streets of cities was early perceived, and they are now in use upon the principal thoroughfares of most of the cities. Cars seating from 22 to 50 passengers are easily drawn by two horses at the rate of 5 or 6 m. an hour, taking the place of a much larger number of omnibuses, and running at considerably less expense. The trucks turning upon pivots, the carriages turn round the corners of the streets without difficulty; and the rails being laid nearly flush with the surface, but little obstruction is presented by them to the passage of vehicles across the track. The importance and utility of this class of railroads having been fully demonstrated by their use in the United States, they have been introduced after much opposition into the principal cities of England, France, Belgium, Germany, and Spanish America. The metropolitan district railway of London is a double track road operated by steam, about 19 m. long, running through a tunnel with occasional open cuts, by a circular route from the Moorgate street station to the mansion house. It was opened in 1863, and cost about \$3,500,000 a mile. Another quick transit railway in London runs from Charing Cross to the city terminus in Cannon street, and is carried on arches over the tops of the houses. It crosses the Thames twice near its termini, and carries an enormous number of passengers. The necessity for means of rapid transit is greater in New York than in almost any other large city, on

account of its excessive length in proportion to its breadth, and the subject has been discussed for many years. One of the plans most persistently urged was that of a viaduct railroad under Broadway, which required the excavation of the entire street, with provision for gas and water pipes, sewerage, and ventilation, to be covered by a continuous arch supporting the surface roadway. A short experimental section of a proposed pneumatic railway was constructed under Broadway in 1870, and various other subterranean projects have been put forth; but plans for elevated roads have met with the greatest favor. One such road, that of the "New York Elevated Railway Company," begun in 1866, has been in successful operation since 1872 from the Battery along Greenwich street and 9th avenue to 30th street. It consists of a single track, carried by longitudinal wrought-iron girders resting on corbels supported by a single line of wrought-iron posts planted along the curbstones. The original plan of operating it by stationary engines and endless wire ropes was abandoned for "dummy engines," each drawing three cars, adapted for 36 passengers each, at the rate of nearly 20 m. an hour. The "Gilbert Elevated Railway Company," chartered in 1872, on the plan of Dr. R. H. Gilbert, propose to build a double track tubular road carried by a trussed iron bridge spanning the street, which is to be supported by a series of arches springing from wrought-iron piers resting upon stone foundations at the edges of the sidewalks. No complete system of rapid transit for the city seeming likely to be constructed under existing circumstances, the legislature in 1875 provided for the appointment of a commission with full power to decide upon a general plan and devise means for carrying it out. This body reported in October in favor of a double track elevated road on each side of the city, to be constructed by the two companies above named, or by another provisionally organized under the powers conferred upon the commission, called the "Manhattan Railway Company." Considerable latitude is allowed as to details, but the whole system is to be completed by Dec. 1, 1878. — *Mountain Railroads.* In 1865-'8 a railroad was constructed up Mont Cenis by the English engineer Fell, in which the traction of the engine is secured by two wheels working horizontally under heavy pressure against the sides of a middle rail. (See CENIS, MONT.) In the railroad up Mt. Washington, New Hampshire, built in 1866-'9, the traction is effected by a cogged wheel working into a cogged rail firmly spiked to the track. The Mt. Rigi railway, in Switzerland, on the same plan, was completed in 1873. A mountain railway has been devised upon which the cars are carried astride of a single line of rails in turn supported upon a line of posts; but this plan has not yet been successfully applied.—For the detailed statistics of railroads in the Uni-

ted States and Canada reference should be made to the manuals published annually in New York by H. V. and H. W. Poor and Edward Vernon; and for methods of construction to the various works in English, French, and German upon railroad engineering.

RAILWAY, Atmospheric. See PNEUMATIC DISPATCH, and PNEUMATIC RAILWAY.

RAIMONDI, Marc' Antonio, an Italian engraver, born in Bologna about 1480, died there subsequent to 1539. He was instructed in design by Francesco Francia, some of whose pictures he engraved as early as in his 15th year. Subsequently he imitated Albert Dürer, and while on a visit to Venice made facsimile copies on copper of his set of 36 woodcuts representing the life and passion of the Saviour, and of another set of 17, representing the life of the Virgin; and the imitation was so exact that Raimondi's prints sold for originals. Dürer was obliged to visit Venice to procure redress, but only succeeded in preventing the use of his monogram. Raimondi soon went to Rome, where he was employed in engraving the choice works of Raphael, and afterward of Giulio Romano. He is said to have excited the wrath of Pope Clement VII. by executing a set of obscene prints, for which he was thrown into prison; but he appeased him by an admirable engraving after Bandinelli's picture of the "Martyrdom of St. Lawrence." The sack of the city by the army of the constable de Bourbon in 1527 reduced him to poverty, and he returned to Bologna. For purity of outline, correct expression, and drawing, he was one of the best engravers on record. The British museum has 500 of his choicest productions.

RAIN, the moisture of the atmosphere condensed into drops large enough to fall with perceptible velocity to the earth. The water thus precipitated is quite pure, except in so far as it absorbs a slight quantity of air, carbonic acid, ammonia, or nitric acid, from the atmosphere. The formation of rain is in general a continuation of the processes of the formation of clouds, dew, and fog. The deposition of moisture depends upon the cooling of the atmosphere, as was first recognized by Dalton (1787), but concerning the precise process by which that cooling is effected erroneous views have been widely entertained. In general it may be said that the temperature of a given mass of warm moist air is lowered in the ordinary course of atmospheric phenomena by one or another of the following four processes: 1, by radiation to the cold sky, according to the views first developed by Fourier (1812) and Wells (1818); 2, by radiation to neighboring masses of cold air, or the cold ground; 3, by mixture with cooler air, a view suggested by Hutton (1787), the slight importance of which was demonstrated by Espy (1833, &c.); 4, by the absorption of heat in the expansion of ascending air, a view first developed by Espy. Radiation takes place especially at night during the winter, when the upper regions of

the atmosphere contain but little moisture to hinder the free radiation of heat, but the result is more frequently snow or cloud than rain; its importance has been well shown by Tyndall (1859, &c.). The third process depends for its effect upon the principle that the density of saturation increases faster than the temperature, so that if we mix two equal volumes of saturated air having different temperatures, the resulting mixture will have a temperature somewhat less than the average of the two, and the quantity of moisture then present will be slightly in excess; but the condensation of even a slight portion of this moisture into cloud evolves latent heat sufficient to elevate the temperature above the point of condensation. The fourth of the above processes is doubtless by far the most efficient of all in lowering the temperature and producing rain. Its precise importance in the economy of the atmosphere has been well shown by the researches of Espy (1833, &c.), Thomson (1862), Peslin (1868), Hirn (1870), Reye (1872), and Hann (1874). According to Hann, the ascent of dry air to higher altitudes must, by reason of its expansion under the lower pressure there prevailing, be from this cause alone attended with a uniform diminution of temperature at the rate of 0.9907° C. per 100 metres of ascent, a rate that becomes 0.9751° when the moisture in the air gives it a relative humidity of 60 per cent. But so soon as by this cooling the air is brought to its point of saturation and the formation of cloud or rain, snow, or hail begins, the evolution of latent heat largely reduces the rate of diminution of temperature. As the saturated air ascends in the form of cloud, its temperature no longer diminishes uniformly, but at a decreasing rate, so that a point may be ultimately reached where its rate of diminution becomes zero. In general, therefore, clouds thus formed are warmer than the adjacent clear air. Doubtless it rarely happens but that rainfall is produced by the concomitant action of two or more of our four principles. Such attempts as have been made to show that electricity has an influence in causing rain must at present be considered wholly unsatisfactory; yet it is acknowledged that the electrical displays which so frequently accompany rain, and especially hail, are but very imperfectly understood. Of other phenomena attending the formation of rain, the most important is the general elevation of temperature on the earth's surface, which is largely due to the great amount of sensible heat thrown into the atmosphere by the condensation of vapor into rain. The other important factor in this elevation of temperature is probably the protection afforded by the clouds against radiation, so that any heat which emanates from the surface of the earth is retained under the covering of clouds.—The distribution of rain over the surface of the globe is of importance to the interests of mankind both as regards its quantity and its frequency. As regards the quan-

tity, accurate measurements are wanting for many portions of the globe, but the following table, condensed from a larger one in Symons's treatise on rain (1867), gives an approximate presentation of the subject:

COUNTRIES.	Annual rainfall, inches.	COUNTRIES.	Annual rainfall, inches.

The extensive mass of information presented in Mr. Symons's table shows that the regular decrease of rainfall as we proceed from the equator to the pole, announced many years ago by Humboldt and others, was a too hasty generalization, and that the data on hand must be further increased, and must be studied with reference to the local influences bearing upon every station, before any exact conclusion can be arrived at, other than this, that the heaviest falls are in the tropics, and that beyond them there is no material decrease. The study of about 1,500 stations by Schmid shows that the rainfall appears not to depend entirely either upon the latitude or the season of the year, but principally upon the relations between the general system of atmospheric currents and the position of the station in reference to geographical and topographical features; thus the enormous rainfall of Cherrapongee, India, depends directly upon the ascent of the current of warm moist monsoon winds over the Cossya hills. In general the geographical distribution of rain proves that rainfall is principally due to condensation in ascending currents of air, and in a less degree to the cool-

ing due to radiation of heat. Concerning the annual and daily period of the rainfall, and the connection between rainfall and the direction of the wind, see METEOROLOGY.—In regard to the frequency of rain, while in many parts of the world a broad distinction exists between the rainy and the wet season, elsewhere we are able to distinguish only between the seasons of short heavy showers and those of long continued gentle rains. A general view of this important feature of the rains throughout the globe is afforded by the accompanying chart, which is due to Wojeikof (1874). This meteorologist says that the normal condition of the oceanic portions of the northern hemisphere is a subdivision into four zones: 1. The equatorial zone of constant rains; this is shifted with the seasons N. and S. of its mean position, and on the average extends from within a degree of the equator to 10° of N. latitude. 2. A rainless zone of trade winds, extending from lat. 10° to 25° or 30° N. 3. The subtropical zone of rain, extending to lat. 40°; into this zone during summer the trade winds extend, and but little rain falls; in winter variable winds with frequent rains occur. 4. A zone of rains with S. W. winds, whose occurrence is distributed pretty equally throughout the year, and which extend from lat. 40° N. to the pole. On passing from the ocean to the land, we find that the third or subtropical zone almost entirely disappears, while the regions of rain at all seasons, and of summer rains, extend further southward. Other features in the distribution of rain will be seen from the map itself. In the article METEOROLOGY will be found information concerning the general laws of rainfall in so far as they pertain to dynamical meteorology. —On the question of the secular variation in rainfall as an item of climatology (specially interesting to civil engineers in connection with the industries of any country), the most extensive investigations have been made by Symons (1870) in England, Schott (1872) in the United States, Rawson (1873) in Barbadoes, and Raulin (1871) in France. The equally important studies of Meldrum (1872) and Köppen (1873) have relation more directly to the eleven-year periodicity. Symons, as the result of all observations in Great Britain from 1725 to 1869, shows that if we take the average of 60 years (from 1810 to 1869) as our standard, the rainfall for each decade will be relatively as in the following table:

DECADE.	Relative rainfall.	DECADE.	Relative rainfall.	DECADE.	Relative rainfall.
1730-39	0·899	1750-59	0·935	1880-89	1·014
1740-49	0·706	1760-69	0·965	1840-49	1·026
1750-59	0·855	1800-09	0·882	1850-59	0·952
1760-69	0·911	1810-19	0·986	1860-69	1·015
1770-79.	1·035	1820-29	1·032		

Schott, in his "Tables of Rainfall in the United States" (Smithsonian institution, 1872,) gives the result of all observations that have

been made at about 1,200 stations, showing that the slight general variations in the rainfall throughout the country have somewhat of a periodical nature; thus along the seaboard from Maine to Virginia, as also in New York, and in the Ohio and Mississippi valleys, there has been an increase (amounting however to

scarcely 1 per cent.) in the average annual precipitation during the last 50 years; on the southern Atlantic coast it appears to have been on the decrease. The following table, condensed from those of Schott, gives the relative rainfall by decades for several sections of the United States:

DECADE.	Eastern and Middle States.	New York State.	The Northwest.	The Ohio Valley.	The Southwest.	The Gulf States.	The South Atlantic States.	California.
1810-'19.....	0.933
1820-'29.....	0.971
1830-'39.....	0.981	0.988	0.926	0.955
1840-'49.....	0.999	0.978	0.969	1.043	1.067	1.000	1.068
1850-'59.....	1.050	1.028	1.031	1.009	0.972	0.962	0.974	1.211
1860-'69.....	1.068	1.057	1.030	0.980	1.032	1.066

Both the British and American series therefore unite in showing that during 60 years there has been no appreciable change.—For further details on the subject of rain, see *Wojeikof, Die atmosphärische Circulation*, appendix No. 38 to Petermann's *Geographischen Mittheilungen* (Gotha, 1874). For information relating to the United States, see the above cited "Tables of Rainfall." With regard to the rainfall in Great Britain, see the annual volumes of "British Rainfall," by G. J. Symons, which contain every variety of information on this subject, including the actual measurements at 1,500 stations and numerous special investigations into sources of error.

RAINBOW, an arch of concentric colored bands, visible usually on a portion of sky overspread with falling rain drops, and always on that side of the observer opposite to the place from which the sun or moon is shining at the time. When the field of falling drops is large, and the illumination thrown on it is bright, a second bow, exterior to and concentric with the first, appears. The inner, or most usual, is termed the primary, the outer the secondary bow. Each shows the same colors, and in the same succession, as those obtained in decomposing a beam of sunlight by means of a dispersing prism of glass; but in the two bows the colors lie in opposite order; in the primary the red is outermost, in the secondary innermost. The primary is always the brighter, and decidedly the narrower. When the light is abundant, this bow is often accompanied by successive bands of red and green, lying just within it or overlapping its violet edge, concentric with it, but extending through parts of its course only, and especially where it nears the horizon; these are called supernumerary bows. The common centre of the two bows is always in the direction of the antisolar point; so that, of course, the rainbow rises at the same rate as the sun declines, or declines if the sun is rising.—The conditions requisite to produce the rainbow have been in a general way understood from an early period, though its causes were not. The earliest known attempt at an explanation of it is that of Aristotle. He observed that from a glass globe filled with water, and set in

the sun, certain colors were always returned at certain angles with the course of the sun's beams; and he properly explained the circular form of the bow, by saying that if the sun-beam passing through the observer's eye be taken as an axis, and the globe be revolved round this axis, and at the same distance from it in all parts of its course, the same colors, preserving their angle with the direction of the sunbeams or of the axis, would be visible through all parts of this course; and hence it followed that a rainbow would result if there were globes enough, and so placed as to reflect colors at the same time from all parts of an arc of such a circle. The colors were supposed to be merely reflected from the globe, or (in the sky) from the drop of water, until *Fleischer of Breslau* (1571), concluding that reflected light does not give colors, stated as a consequence that the rays must enter the drops. Of the light falling on the presented side of the drops, of course part will be reflected, but another part will enter and be refracted at the same time; striking on the inner opposite surface of the drop, part of this beam will emerge and escape, while another part will be reflected; and on again striking the side of the drop toward the spectator, though a portion of this residue of the first beam undergoes a second reflection, another portion emerges, again refracted, and, if at a proper angle, then passes to the eye. *Kepler* agreed in this view, but erred in supposing the entering light to be that of rays grazing or tangent to the upper sides of the drops. *Antonio de Dominis*, in 1611, carefully repeated the experiments with the glass sphere filled with water, showing in sunlight very vivid colors to a great distance, and each at an angle of its own. *Descartes* showed: 1, why there must be on the illuminated field of falling drops a circular belt of colors bright enough to be seen, and always of a definite diameter; and 2, that the colors are in separate bands or stripes in this, because they are not equally refracted. He gave the reasons why the colors must be just where they were, and in bands just so broad, if they all appeared; he could not tell why they must all appear. This element *Newton* supplied, when he discovered (1666) that sunlight is decomposable

into a fixed number of different colored rays, refracted or bent at the same time in different but definite degrees, so that they must appear, under given circumstances, separated just so much, and always in the same successive order. This result will follow, then, whether sunlight is dispersed by prisms or by transparent spheres, as water drops. The mathematical theory, which belongs to Descartes, may be found in the higher text books of optics, and

is illustrated by the accompanying diagram taken from Deschanel's "Natural Philosophy." If a ray of light pass through the centre of a sphere or drop, its course is in an axis of the sphere or drop; it is not refracted. A ray parallel with this, and very near it, is refracted within the drop, toward this axis, but very slightly. Other rays, further and further from the axis, are refracted more and more toward it, but yet so as to fall, by lessening degrees, further from it on the inner or second surface of the drop; until, as Descartes proved, a ray, *Sb* or *Sa*, entering the upper side of the drop, when this is above the eye, and at a point for which its angle of incidence is 60° , will strike on the inner surface as far as any ray can do from the axis; the rays incident at greater angles than this, up to 90° , deviating again toward the axis. Of course, near this limit, the deviation is very slight for rays coming on either side, so that much more light within the drop will be accumulated just at this point of the second surface than at any other; and though part of it emerges here, a sufficient quantity is reflected, and that in rays which preserve a parallel course (*bO* or *aO*), after leaving the drop in the direction toward the spectator, to form a compact, parallel beam, bright enough to affect the eye at a great distance. The apparent radii of the arcs constituting the rainbow are constant, or nearly

so; they are expressed by the angles between the axis *OZ* and the lines *Oa*, *Ob*, &c., and are as follows: in the primary bow, for the violet $40^\circ 17'$, for the red $42^\circ 2'$; in the secondary bow, for the red $50^\circ 57'$, for the violet $54^\circ 7'$. A tertiary bow, formed by rays that have been thrice reflected within the raindrops, is possible at a distance of about $43^\circ 50'$ from the sun; but this is very rarely visible, owing to its faintness and other causes. From the above explanation, the following consequences are obvious: that the ordinary rainbows must be on the side of the observer opposite the sun; that their centres must be directly opposite the sun; that they must move with the motion of the sun, declining in the morning, and rising if seen at evening; that when the sun and the observer are in the same horizontal plane, as at sunset, the bows will be semicircles, and their altitudes then about 42° and 54° ; that they can never approach nearer than this to the zenith, unless the observer be on an elevated position, so that the sun can shine from below the horizontal plane in which he is; that at the tops of high mountains they may be seen as complete circles; and that, to one at the ordinary level, in the low and middle latitudes, they are never seen between about 9 o'clock in the morning and 3 o'clock in the afternoon; while in higher latitudes, where the sun is always very low in the sky, they may occur even at midday. If the rain is near, the bows may sometimes be seen prolonged upon the landscape. The small water drops constituting spray may afford a rainbow; hence it is seen in the mist arising near cataracts, and, because near, is then small, and may appear as a complete circle. A partial bow may be observed at times in drops of dew or rain upon herbage or grass. The formation of the supernumerary bows was explained by Young (1804), as due to interference of sets of rays emerging at angles very nearly those of the proper colors of the bows. Biot, and afterward Brewster, have shown that in all rainbows the light is polarized in the radial planes passing through the axis *OZ*, and hence polarized by refraction and reflection.—The lunar rainbow is usually single, the primary bow only, and is often white; when colored, it is but faintly so.—When the drops of rain are exceedingly fine, as in the case of clouds and fog, the rainbow proper is replaced by bows formed by the reflection and interference of light from these fine particles. The laws of these fog bows are deducible from the same principles that have served to explain the rainbow. The phenomena themselves are exceedingly brilliant; they were observed by Sykes in 1829 (see "Philosophical Transactions," 1835), but far more perfectly by the aeronauts of the past few years; beautiful examples are recorded in Glaisher's "Travels in the Air" (London, 1870).—The floating ice spiculæ or crystals that compose those higher clouds called cirri

affect the solar rays even more curiously than the spherical drops of water, causing the varied phenomena of parhelia, all of which are explainable on principles not materially different from those that apply to the rainbow proper.

RAIN CROW. See Cuckoo.

RAIN GAUGE, an instrument for measuring the amount of rain which falls upon a given area during a certain space of time. For approximate purposes a tub or bucket, with a thin-edged mouth, placed in a horizontal position for catching the rain, whose depth may afterward be measured by means of a graduated rod, may be employed, and if well constructed and used with care may fulfil most of the requirements of exactness. It is more common, however, to catch the fall in an accurately made funnel whence it flows into a holder, whose form is immaterial; it is subsequently measured either by weighing or by means of a tall graduated cylinder, which gives the average depth of the rainfall. The holder should have a capacity abundantly sufficient to receive all the rain that may be caught. It is difficult to employ a rain gauge to measure a snowfall unless the air is perfectly still, as the wind interferes with the reception of the snow; it is therefore generally preferable after a snow storm to take a cylindrical vessel of sufficient depth and with it cut out a section of the snow from some region which has an average depth of covering; the snow thus collected should be melted or dissolved in a known quantity of water and measured. For special studies different forms of gauges are employed, in which the opening of the mouth may be horizontal, inclined, or vertical; rain gauges are also attached to wind vanes so as always to be turned toward the wind. Very great discretion is required in the selection of the site of the instrument; the standard position of the mouth of the gauge is 8 to 16 in. above the surface of a broad level lawn; gauges in the neighborhood of trees and buildings or on the tops of isolated buildings are not allowable except for the purpose of investigation. —For the numerous details in reference to this important subject, see the annual volumes of Symons on "British Rainfall."

RAINS, a N. E. county of Texas, watered by Lake fork and other tributaries of the Sabine river; area, about 220 sq. m. It has been formed since the census of 1870. The surface is undulating and the soil fertile. There is considerable timber. Indian corn, wheat, cotton, tobacco, sweet potatoes, cattle, &c., are raised. Capital, Emory.

RAINY LAKE, a body of water, 50 m. long and of irregular width, on the border of Minnesota and British America, discharging through Rainy or Rainy Lake river (100 m. long) into the lake of the Woods. It receives the river La Seine, the outlet of Lac des Mille Lacs, from the northeast, and from the east the waters of a chain of lakes lying along the international frontier, and having their source in the height

of land dividing the streams that flow into Lake Superior from those that flow into Lake Winnipeg. It contains numerous islands. Near its outlet are the falls of Fort Francis, 20 ft. high. The lake and Rainy river below the falls are navigable by steamers.

RAISIN (Fr., a grape), the dried fruit of the European grape vine (*vitis vinifera*). None of our native grapes (see GRAPE) has yet afforded raisins suitable for commerce, though one or two varieties encourage the hope that some may yet be produced which will make good raisins. The European grape succeeds perfectly in California, and the production there is already sufficient to supply the home demand. The raisins of commerce are produced in the countries around the Mediterranean. The varieties recognized in trade arise not merely from the original differences in the grapes, but also from the methods of drying. Among the best sorts are those known as the Malaga, muscatel, or "sun raisins;" these are dried upon the vines, as, unlike most fruits, the grape does not drop when ripe; the stem to each bunch when ripe is twisted or partly severed, and the grapes soon shrivel by the evaporation of the water they contain, and become sweeter by the consequent concentration of the pulp; when dried the bunches are taken off and carefully placed in boxes with sheets of paper separating the layers. These raisins, better than any other sort, retain the freshness and bloom of the fruit, and when fresh have less of the saccharine exudation which is found upon most of the other varieties. The common kinds of raisins are prepared by drying the ripe grapes after they are picked, either in the sun or in heated rooms, and while they are drying dipping them in a lye of wood ashes and barilla, of specific gravity 1.110, to every four gallons of which is added a pint of oil and a handful of salt; the effect of this is to cause a saccharine exudation to take place, which forms concretions upon the raisins and coats them with a thin varnish. The best raisins of this kind are hung on lines to dry in the sun, and as they begin to shrivel they are dipped in the lye once or twice and hung up again to complete the drying. The raisins known as sultana come from Smyrna; they are from a small grape without seeds, and come packed in drums. The black Smyrna raisins are also small, but have very large seeds, and are generally free from sugary concretions.—A very important variety of raisins are called currants, or Zante currants, and are popularly supposed to be common currants preserved in some manner; they are, however, produced by a very small-sized grape, largely cultivated at Patras, in Zante, Ithaca, and Cephalonia, and in the Grecian archipelago. The grapes are no larger than peas, and the bunches are only about 3 in. long. After drying in the sun, they are stored in large masses, which become so compact from the sugar which exudes from them, that they have to be forcibly dug apart for packing. For shipment

they are placed in casks, and made into a solid mass by treading. They were formerly called corinths, and are mentioned in old books as currans. The demand for them is very large in the United States.—Raisins are sometimes employed instead of grapes in making wine, and among the ancient Greeks and Romans some of the best wines were of this character.

RAJAHMUNDRY, or **Rajamahendri**, a town of British India, in the province and 280 m. N. N. E. of the city of Madras, capital of a district formerly of the same name, but now known as the district of Godavery; pop. between 15,000 and 20,000. It is on the N. bank of the Godavery river, here nearly two miles wide. The houses are mainly of mud, but one story high, and roofed with tiles.—The district (pop. in 1872, 1,584,179) includes the rich alluvial delta region of the Godavery, which has been made very prosperous by the existing system of irrigation. The chief products are rice, millet, maize, cotton, indigo, tobacco, and sugar cane. Coringa, at the mouth of the Godavery, is the principal port.

RAJPOOTANA (formerly **RAJASTHAN**), a territory of British India, consisting of 18 native states, principally inhabited by Rajpoots, in subsidiary alliance with the British government. This aggregation of states, which completely encloses the district of Ajmeer, extends E. and W. a distance of 520 m. between lon. 69° 35' and 78° 10' E., and N. and S. 480 m. between lat. 23° 15' and 30° 10' N. It is bounded N. by Bhawalpoor and the Punjaub; E. by the Northwest Provinces, the Chitore hills, and the river Chumbul, a tributary of the Jumna, beyond which lie the dominions of Sindia; S. by Malwa and Guzerat; and W. by Sinde. For purposes of British intervention and control the region is divided into seven political agencies, and the following table exhibits the area and population of the several states in each:

DIVISIONS.	Area in square miles.	Population.
Mewar Agency:		
Odeypoor or Mewar	11,614	1,161,400
Purtabgurb	1,460	150,000
Dongurpoor	1,000	100,000
Banswara	1,500	150,000
Jeympoor Agency:		
Jeympoor	15,000	1,900,000
Kishengurb	720	70,000
Bickaneer	17,676	539,000
Marwar Agency:		
Joodpoor or Marwar	86,672	1,783,600
Jessulmeer	12,252	70,000
Harattee Agency:		
Boondee	2,291	220,000
Kotah	5,000	433,400
Jhalawar	2,500	220,000
Tonk	1,890	182,000
Eastern States Agency:		
Dholepoor	1,626	500,000
Bhurtpoor	1,974	650,000
Kerowlee	1,260	140,000
Alwur (or Ulwur) Agency:		
Alwur	3,000	778,596
Serohee Superintendency:		
Serohee	3,000	55,000
Total	120,345	9,105,996

The Aravulli mountains are for the most part within the limits of Rajpootana, extending from Ajmeer southwesterly between Marwar and Mewar to Mt. Aboo, near the southern frontier of the country in the state of Serohee, where they attain a height of 5,650 ft. The regions of Marwar immediately W. of the range are watered by the river Loonee, which rises on its western slope and flows S. W. more than 200 m. into the runn of Cutch. Westward, beyond this river, a great part of Rajpootana is a sandy expanse of desert, extending from Joodpoor, the capital of Marwar, through Jessulmeer, the westernmost of the Rajpoot states. The towns scattered over this arid tract are situated in oases, and among them are some of the most salubrious and beautiful inhabited places in India. The state of Bickaneer, in the north, bordering upon Bhawalpoor, is also a dry and desolate region. Greater fertility prevails in the states which lie N. E. and E. of Ajmeer and the Aravulli range, and which are watered by the Chumbul and its tributaries, as well as by other affluents of the Jumna. Directly N. of Ajmeer, on the boundary between Jeympoor and Joodpoor, is the Sambhur salt lake, 22 m. long and 6 m. broad, which yields a valuable product of salt, the annual receipts from the Joodpoor portion being about £40,000. There are several smaller lakes in the country.—Of the 18 states of Rajpootana, 15 are occupied principally by Rajpoots; there are two Jat states, Dholepoor and Bhurtpoor; and the population of Tonk is Mohammedan. Each of the seven political agencies is under the charge of a British officer, who maintains constant political relations with the native ministers of state. The chief administrative and diplomatic authority for the entire territory is vested in a political agent of the viceroy, who resides at Ajmeer and on Mt. Aboo. An interjurisdictional court of wakils is held under the presidency of the Marwar agent, for the settlement of all disputes between the several states of Rajpootana. In March, 1873, the military force stationed in Rajpootana comprised 2,919 native infantry, 1,472 native cavalry, and 42 British officers.—The Rajpoots, by far the most numerous portion of the population, who claim to be descendants of the original Kshattriya caste of the Hindoos, appear to have inhabited the country from the earliest historical period. Notwithstanding their formidable resistance to the Mohammedan invasion, they became peaceful subjects of the earlier emperors, who treated their religion with tolerance; but in the time of Aurungzebe his oppressive measures induced them to take part in the war of the Mahrattas against him. Subsequently Rajpootana was invaded by various marauding armies, but in 1761 the Rajpoots had achieved practical independence both of the Mohammedans and of the Mahrattas. In the early part of the present century Sindia and Holkar exacted tribute from the chiefs, and the Pindarrees made re-

peated incursions into the country, which were so destructive that British intervention was necessary to save the people from ruin; and the principal Rajpoot states were transferred to the English, by the consent of their own rulers, in 1818, after the British forces had defeated Holkar and expelled the Pindarree robbers. A few were acquired earlier, and others subsequently. Their present political status is that of subject-allied states.—See Tod's "Annals and Antiquities of Rajasthan" (London, 1829), and Malletson's "Historical Sketch of the Native States of India" (1875).

RÁKÓCZY, a noble family of Transylvania, several members of which were princes of that country. Of these, **GEORGE I.** (1631-'48) made himself conspicuous by his coöperation with the Swedes in the latter years of the thirty years' war, when he succeeded in forcing the emperor Ferdinand III. to restore the liberties of Hungary by the treaty of Linz (1645). (See *Actes et documents pour servir à l'histoire de l'alliance de George Rákóczy avec les Français et les Suédois*, &c., by A. Szilágyi, Pesth, 1875.) His son **GEORGE II.** was less successful in a war with Poland (1657). The most celebrated member of the family, **FRANCIS II.**, grandson of the preceding, born in 1676, died at Rodosto, Turkey, April 8, 1735. After the death of his father, Francis I., and the surrender of Munkács to the Austrians after a heroic defence by his mother, he was brought up under the care of the court of Vienna, and during the insurrection under Tökölyi was placed under the Jesuits in Bohemia, who strove in vain to induce him to abjure Protestantism. Subsequently he received part of the estates of his relatives, and was permitted to reside in Hungary. Accused of being engaged in a conspiracy to excite rebellion, he was taken in May, 1701, to Austria, and confined in a dungeon at Wiener-Neustadt; but he escaped and fled to Poland, and in 1703 suddenly appeared in the vicinity of Munkács, collected an insurrectionary band, and issued a bitter manifesto against Austria. He was subsidized by Louis XIV., then engaged in the war of the Spanish succession, and after a short time had most of Hungary and Transylvania in his power, and even threatened Vienna. The revolted Hungarian districts and cities in 1705 formed a confederation similar to those of Poland, appointing Rákóczy, who had previously been elected prince of Transylvania, their chief with the title of *dux* (Hung. *vezér*). But in August, 1708, while investing Trentschin, he was surprised and badly defeated by the Austrian general Heister, and barely escaped. From this time the arms of Austria were in the ascendant, and her victories in the field were assisted by the dissensions which long before had manifested themselves among the confederates. Rákóczy having gone to Poland, in order to meet with Peter the Great of Russia, a peace was concluded in his absence between Austria and the confederates at Sztatmár in 1711. Af-

ter living several years in France and Spain, Rákóczy went to Turkey, and with other refugees passed the rest of his life at the castle of Rodosto on the sea of Marmora. He wrote a narrative of the struggle in Hungary under the title of *Mémoires sur les révolutions de Hongrie* (the Hague, 1738). He also composed meditations, hymns, soliloquies, and a commentary on the Pentateuch.

RAKOS. See PESTH.

RALE, or **Rasles**, Sébastien, a French missionary to the North American Indians, born in Franche-Comté in 1658, killed at Norridgewock, Maine, Aug. 12, 1724. He was a Jesuit, and taught Greek at a college in Nîmes. He embarked at La Rochelle, July 23, 1689, arrived in Quebec on Oct. 13, and was stationed successively at the Abenaki mission of St. Francis near the falls of the Chaudière, then in the Illinois country, and finally at Norridgewock on the Kennebec. He arrived here at least as early as 1695. The English settlers ascribed their quarrels with the Abenakis to his influence, accused him of instigating the forays of the savages upon the settlements along the coast, and set a price upon his head. A party of New Englanders under Capt. Hilton attacked Norridgewock in 1705, but withdrew after burning the church. A second expedition in 1722 pillaged his cabin and the church, which had been rebuilt, but the missionary escaped to the woods. Among the papers which they carried off was his dictionary of the Abenaki language, now preserved in the library of Harvard college, and printed in the memoirs of the American academy of arts and sciences, with an introduction and notes by John Pickering (4to, Cambridge, 1833). In 1724 a party of 208 men from Fort Richmond surprised Norridgewock, killed a number of the Indians, and shot Father Rale at the foot of the mission cross.—See a memoir of him by Convers Francis, D. D., in Sparks's "American Biography" (2d series, vol. vii.).

RALEIGH, a S. county of West Virginia, bounded E. by the Kanawha or New river, and watered by Coal river and other tributaries of the Kanawha; area, about 380 sq. m.; pop. in 1870, 3,673, of whom 16 were colored. The surface is mountainous. The chief productions in 1870 were 7,509 bushels of wheat, 73,657 of Indian corn, 16,278 of oats, 6,720 of potatoes, 5,769 lbs. of tobacco, 11,338 of wool, and 41,635 of butter. There were 827 horses, 3,357 cattle, 5,462 sheep, and 4,120 swine. Capital, Raleigh Court House.

RALEIGH, a city of Wake co., North Carolina, capital of the county and state, on the Raleigh and Gaston and the Raleigh and Augusta Air Line railroads, and on the North Carolina division of the Richmond and Danville railroad, 6 m. W. of the Neuse river, and 230 m. S. by W. of Washington; lat. 35° 47' N., lon. 78° 48' W.; pop. in 1850, 4,518; in 1860, 4,780; in 1870, 7,790, of whom 4,094 were colored. It is pleasantly situated on

an elevation, and is very regularly laid out. In the centre is a park of ten acres called Union square, from which extend four streets, 99 ft. wide, dividing the city into four parts, in each of which is a square of four acres. The state house is of granite, 166 ft. long and 90 ft. wide, and cost \$531,000. The old state house, containing Canova's statue of Washington, was burned in 1831. Other public buildings are the state geological museum, the state institution for the deaf and dumb and the blind, the state insane asylum, the state penitentiary, the county court house, and the county jail. The United States court house and post office, a fine granite building, is in course of erection (1875). The state supreme court and the United States circuit court for the eastern district of North Carolina are held here. There is a large trade in cotton and dry goods. The city contains the shops of the Raleigh and Gaston and Raleigh and Augusta Air Line railroads, two iron founderies, two cigar manufactories, a manufactory of pumps, two or three marble yards, several printing and binding establishments, and three national banks, with an aggregate capital of \$700,000. There are three hotels, two public halls, separate public schools for white and colored children, three female seminaries, under the management of the Baptists, Episcopalians, and Presbyterians respectively, several private schools, two libraries in the state house (the law library with 4,000 volumes, and the state library with 25,000 volumes), two daily, one semi-weekly, and nine weekly newspapers, and Baptist, Christian, Episcopal, Methodist, Presbyterian, and Roman Catholic churches.—The site of Raleigh having been selected as the seat of government in 1788, it was laid out in 1792 and incorporated as a city in 1794.

RALEIGH, or Raleigh, Sir Walter, an English courtier and navigator, born at Hayes, Devonshire, in 1552, beheaded at Old Palace yard, Westminster, Oct. 29, 1618. At the age of 17 he left Oriel college, Oxford, to join a troop sent to the aid of the Huguenots in France, and afterward served, it is said, in the Netherlands. On his return to England he found that his half brother, Sir Humphrey Gilbert, had just obtained a patent (1578) for establishing a plantation in America, and entered into the scheme. They put to sea in 1579; one of their ships was lost, the remainder, it is said, were crippled in an engagement with a Spanish fleet, and they returned without making land. The next year Raleigh served as captain against the Desmond rebellion in Ireland. On his return, it is said that he met the queen one day as she was walking, and spread his mantle over a miry place in the path for her to tread upon it. Struck by his gallantry, Elizabeth admitted him to court, loaded him with attentions, and employed him to attend the French ambassador Simier on his return to France, and afterward to escort the duke of Anjou to Antwerp. He soon made

use of his influence to promote a second expedition to America. Prevented by an accident from going in person, he left the command of the fleet to Sir Humphrey Gilbert, who sailed from Plymouth with five ships in 1583, and reached Newfoundland, of which he took possession in the name of the queen; but his ships were dispersed, and Gilbert himself on the voyage home was lost. Raleigh, obtaining from Elizabeth an ample patent and the title of lord proprietor over an extensive region, fitted out two vessels under the command of Philip Amidas and Arthur Barlow, who reached Ocracoke inlet on the shore of North Carolina in July, 1584. They explored Pamlico and Albemarle sounds, and returned to England in September with a glowing account of their discoveries. Elizabeth, as a memorial of her state of life, called the newly found region Virginia, and conferred knighthood upon Raleigh, with a lucrative monopoly of wines. Raleigh, now a member of parliament for Devonshire, obtained a bill confirming his patent, raised a company of colonists, and in 1585 sent out under command of Sir Richard Grenville seven vessels with 108 emigrants. The colony landed at Roanoke island about July 1, and Grenville soon returned home with the ships, capturing on his way a rich Spanish prize. In the mean time Raleigh had been appointed seneschal of the duchies of Devon and Cornwall and lord warden of the stannaries, and had obtained a grant of 12,000 acres of forfeited land in Ireland. His favor at court continued to increase, but among the multitude he was one of the most cordially hated persons in England. In 1586 two parties were sent out to Virginia with reinforcements, but they found the settlement abandoned. The disheartened colonists had gone home in Sir Francis Drake's ship, and the fruit of their expedition had been little more than the introduction into England of tobacco and potatoes. Raleigh now determined to found an agricultural state, and in April, 1587, despatched a considerable body of emigrants to make a settlement on Chesapeake bay. He granted them a charter of incorporation, and appointed a municipal government "for the city of Raleigh," intrusting the administration to John White, with 12 assistants. They founded their city not on the bay, but on the site of the former settlement at Roanoke island, and when their ship returned sent Gov. White back to England to expedite reinforcements. But two ships which Raleigh sent out with supplies fell into the hands of the French. His means were now exhausted, and the colonists all perished. Meanwhile Raleigh had exerted himself to assist the preparations for resisting an expected Spanish invasion; in 1587 he was a member of the council of war, and had command of the forces in Cornwall, of which county he was lieutenant general; and in 1588, when the great armada appeared in the channel, he hung upon its rear in a vessel of his

own, annoying it by quick and unexpected movements. He was in Drake's expedition to restore Dom Antonio to the throne of Portugal (1589), and captured some Spanish vessels intended for a fresh invasion of England. Visiting Ireland, he saw Edmund Spenser, with whom he had already contracted a friendship, and brought him to Elizabeth's court to present to her majesty three books of the "Faerie Queen." In the hope of shattering the power of Spain in the West Indies, he collected, mostly at his own expense, and sailed with a fleet of 13 vessels, and with Frobisher captured the largest Spanish prize that had ever been brought to an English port. Soon after this (1591) it was discovered that he had debauched one of the queen's maids of honor, the daughter of Sir Nicholas Throgmorton; and though he married the lady and lived with her happily till his death, such an offence was not to be overlooked. Imprisoned for two months and banished from court, he employed the period of his disgrace in planning an expedition to Guiana. He set sail with five ships in 1595, and returned the same year, after exploring a considerable extent of country about the Orinoco and destroying the Spanish settlement of San José. He published on his return a highly colored account of this voyage, in his "Discovery of the large, rich, and beautiful Empire of Guiana" (4to, 1596). He coöperated in the capture of Cadiz, was wounded, and was restored to the queen's favor. In 1597 he sailed under Essex against the Azores, and took Fayal, but quarrelled with his commander and returned. He had obtained a grant of the manor of Sherborne in Dorsetshire, which he magnificently embellished, was sent with Lord Cobham on a joint embassy to the Netherlands in 1600, and on his return was made governor of Jersey. The execution of Essex, which he was supposed to have had an agency in effecting, added greatly to the public odium with which he was regarded, and the death of Elizabeth in 1603 proved a final blow to his fortunes. On the accession of James he was stripped of his preferments, forbidden the royal presence, and shortly afterward arrested on charge of conspiring to place Lady Arabella Stuart on the throne. He made an attempt, probably feigned, to commit suicide. Convicted on the slightest evidence, after a rancorous speech from Attorney General Coke, he was reprieved and sent to the tower, and his estates were given to Carr, afterward earl of Somerset. During his 13 years' imprisonment he composed his "History of the World" (1614), a work greatly superior both in style and matter to the English historical compositions which had preceded it. For six years his wife was permitted to bear him company. At last, Villiers having supplanted Somerset in the royal favor, Raleigh was liberated in March, 1615, but not pardoned. Obtaining from James a commission as admiral of the fleet with ample privileges, he fitted out 14 ships, and reached Guiana with the loss of

two in November, 1617. Keymis was sent up the Orinoco with 250 men in boats, landed at the Spanish settlement of St. Thomas, and, in defiance of the peaceable instructions of James, killed the governor and set fire to the town. Raleigh's eldest son was killed in the action. Unable either to advance or to maintain their position, they retreated in haste to the ships, a Spanish fleet, which had been informed of their intended movements, hovering near them. Keymis, reproached for his ill success, committed suicide; many of the sailors mutinied; the ships scattered; and Raleigh landed at Plymouth in June, 1618, completely broken in fortune and reputation. He was soon arrested, and failing in an attempt, by feigning madness, to escape to France, was committed to the tower. The Spanish ambassador demanded his punishment, and James was not reluctant to grant it. The judges decided that, being still under judgment of death pronounced in 1603, he could not be tried again, and it was resolved to execute the former sentence.—Raleigh was a man of imposing person, dauntless courage, extensive knowledge, and varied accomplishments. His speeches show a knowledge of the principles of political economy far above his time. His literary productions, besides those already mentioned, include some short poems, "Maxims of State," "The Cabinet Council," "The Sceptic," and "Advice to his Son;" and he is also remembered in the world of letters as the founder of the "Mermaid club." His life has been written by William Oldys, Arthur Cayley (2 vols. 4to, London, 1805-'6), Mrs. A. T. Thomson (8vo, London, 1830), P. F. Tytler (Edinburgh, 1833), and Edward Edwards (2 vols., London, 1868). His poems were collected by Sir E. Brydges (London, 1814), his "Miscellaneous Writings" by Dr. Birch (2 vols., 1751), and his "Complete Works" were published at Oxford (8 vols., 1829).

RALLS, a N. E. county of Missouri, separated from Illinois by the Mississippi river, and intersected by Salt river; area, about 525 sq. m.; pop. in 1870, 10,510, of whom 1,255 were colored. The surface is broken or undulating, comprising prairie and timber land in nearly equal proportion. The soil is very fertile. The chief productions in 1870 were 158,728 bushels of wheat, 292,534 of Indian corn, 125,677 of oats, 15,740 of potatoes, 32,533 lbs. of wool, 127,793 of butter, and 8,962 tons of hay. There were 4,715 horses, 1,150 mules and asses, 3,668 milch cows, 11,470 sheep, and 16,660 swine. Capital, New London.

RALPH, James, an English author, born in Philadelphia, Pa., died in Chiswick, England, Jan. 24, 1762. He was a schoolmaster in Philadelphia, went to England in company with Benjamin Franklin in 1724, wrote "The Fashionable Lady, or Harlequin's Opera," performed in 1730, and altered several old plays. He attached himself to the faction of the prince of Wales, and on the accession of George III. received a pension, but only lived to enjoy it six

months. His only political work now remembered is an octavo volume defending the memory of Queen Mary and Queen Anne, in answer to the duchess of Marlborough's "Account of her Conduct." He continued anonymously Guthrie's history, under the title of a "History of England during the Reigns of King William, Queen Anne, and George I."

RAM, Water. See HYDRAULIC RAM.

RAMADAN, or Ramazan (the hot month, from Arab. *ramida*, to glow with heat), the ninth month of the Mohammedan year, during the whole of which a rigorous fast is commanded by the Koran, in commemoration of the first divine revelations received by the prophet. No one is allowed food or drink from sunrise until the appearance of the stars; and those who are unable to observe the ordinance on account of sickness, must fast during the month immediately succeeding their recovery. The Moslems compensate themselves for this rigor during the day by feasting at its close; and Ramadan is succeeded by three days of feasting called the little Bairam, the two corresponding to the Christian Lent and Easter. (See BAIRAM.)

RAMAYANA. See INDIA, RELIGIONS AND RELIGIOUS LITERATURE OF, vol. ix., p. 223.

RAMBOUILLET, a town of France, in the department of Seine-et-Oise, 30 m. S. W. of Paris; pop. in 1872, 4,725. It contains a palace built in the shape of a horse shoe, protected by ditches and flanked with five strong towers, in one of which Francis I. died. It is surrounded by beautiful gardens planned by Le Nôtre and a large park. The extensive forest adjoining was the favorite sporting ground of Charles X., who after the triumph of the revolution of July, 1830, in Paris, made an ineffectual show of resistance here. A school for daughters of officers was established in the palace in 1852.

RAMBOUILLET, Catherine de Vivonne, marchioness de, a French leader of society, born in Rome in 1588, died in Paris, Dec. 2, 1665. Her father was Jean de Vivonne, marquis of Pisani, French ambassador in Rome, and her mother was a Roman lady. At an early age she married Charles d'Angennes, afterward marquis de Rambouillet. After arriving in Paris she was shocked by the immorality and puerility of the court circles, gathered round her a select society, and fitted up the hôtel Rambouillet with a special view to its convenience for literary reunions. Here she dispensed generous hospitality for half a century alike to authors, wits, and persons of rank, who now for the first time met on a footing of equality. Her daughter Julie, afterward duchess de Montausier, was the idol of her guests, of whom the women were called *les précieuses*, and assumed classical and romantic names. The conversational brilliancy which ever afterward distinguished the great saloons of Paris originated

here, and the French academy took its rise from one of the literary reunions which grew out of those at the hôtel Rambouillet. Voiture, one of the original members of the academy, was the most assiduous and popular habitué of the house; Corneille and Bossuet first came into notice here; Descartes found here warm admirers; Balzac, La Rochefoucault, Malherbe, Mme. de Sévigné, and hosts of other distinguished persons were among the visitors. During the first half of the 17th century these gatherings exerted a noble influence on the French language and literature, but subsequently declined, chiefly owing to the mannerism of Mlle. de Scudéry and other ladies, and never recovered from the effect of Molière's comedy *Les précieuses ridicules* (1659), though this was aimed particularly against numerous extravagant offshoots of the hôtel Rambouillet.—See *Mémoires pour servir à l'histoire de la société polie en France pendant le dix-septième siècle*, by Roederer (Paris, 1835), and *Précieux et précieuses*, by Charles Livet (1859).

RAMEAU, Jean Philippe, a French composer, born in Dijon, Oct. 25, 1683, died in Paris, Sept. 12, 1764. He was the son of an organist, and was educated for the bar, but at the age of 18 went to Italy as a violinist. He returned to Paris in 1717, and was organist in several churches. He composed anthems, cantatas, and pieces for the organ and the harpsichord, published a *Traité de l'harmonie* (1722) and *Nouveau système de musique théorique* (1726), and composed the music for several of Piron's and Voltaire's comedies and other pieces, the best being that to Pellegrin's *Hippolyte et Aricie* (1733). His numerous operas and theoretical writings are now obsolete.

RAMESSES, or Ramses, the name of 14 or 15 Egyptian kings of the 19th and 20th dynasties, called collectively the Ramessids. Rameses I. was the first monarch of the 19th dynasty, beginning, according to Mariette, about 1460 B. C. He was succeeded by Seti I. Rameses II., son of Seti I., was one of the greatest of Egyptian kings, and a detailed account of his reign, as well as of that of Rameses III., in many respects an equally eminent ruler, is given in the article EGYPT, vol. vi., p. 462. Very little is known of the reigns of the others.

RAMIE, one of the East Indian names, and the one generally adopted in this country, for the plant producing the fibre called China grass. Its botanical name is *Bahmeria nivea*, and it is found either cultivated or wild throughout the greater part of tropical and eastern Asia; the genus (named after G. R. Böhmer, a Wittenberg botanist of the last century) belongs to the *urticaceæ* or nettle family, and is nearly related to the true nettles; but the plants are not armed with stings, and the fertile flowers, instead of a two- to five-parted calyx (see NETTLE), have a tubular calyx, which closely surrounds the small nut-like fruit; one species, a coarse nettle-like weed (*B. cylindrica*), is very common in moist shady places in

most parts of the United States. The ramie is a perennial, somewhat shrubby plant, growing 4 ft. high, and throwing up numerous stems as thick as the little finger, which bear opposite, pointed, serrate leaves, 6 in. long by 4 in. broad, on long hairy petioles; their upper surface is

Ramie (*Boehmeria nivea*).

dark green, but underneath they are covered with a very white down, suggesting the specific name *nivea*, snowy, which makes the contrast between the two surfaces very marked. The inconspicuous flowers are in little clusters upon axillary stalks. A variety, *candicans*, which has been called *B. tenacissima*, is cultivated in the same countries as the type, from which it differs in being more robust and in having the under surface of the leaves scarcely whitened. The useful portion is the fibre of the inner bark, which in eastern countries is stripped from the stems in two long pieces, cleared of extraneous matter, dried, and assorted according to the fineness of the fibre, which depends in great measure upon the rapidity with which the plant grew. For weaving, the fibres, after being bleached, are slowly picked apart by the fingers into threads coarser or finer according to the intended fabric. This plant has been used in China and other eastern countries from time immemorial to make a great variety of fabrics, some having the fineness and brilliancy of silk; the woven material was early an article of commerce, and considerable quantities of the fibre are now imported by England and France and used as a substitute for or to mix with silk. In warm countries three crops of stems are obtained in the year, the second affording the finest fibre; it may be raised from seed, but the usual method is to divide up the old plants; the sets are planted in rows, about 5 ft. apart, and very thickly in the rows, as straight stems are obtained only when they are crowded. It needs a rich and well drained soil, and a climate

where there are no hard frosts; in northern China the planters take up the roots and keep them in pits over winter. The proper time for cutting is indicated by the turning brown of the stems at the base. The plant was introduced into Jamaica in 1854, and in 1855 was sent to the botanic garden at Washington; but no serious attempt was made to engage in its culture till 1867, when an excitement like that formerly caused by *morus multicaulis* seemed imminent. On account of the deranged condition of labor southern planters were eager for any crop which could be raised with less manual labor than cotton; great stories were told of the productiveness and profit of ramie, and a lot of plants brought from Mexico, where it had been introduced a few years before, were sold at high prices. For a few years those who raised plants for sale found it profitable, but when the product became considerable the heretofore unconsidered problem of the disposal of the crop came up; to prepare the fibre in the eastern manner by hand was impossible, and the crude material was too bulky for export. Machines were invented for separating the fibre without encouraging success, and the excitement subsided.—The seeds of the wood nettle, *Laportea Canadensis*, a tall, coarse, stinging, nettle-like plant, have been offered as those of the “American ramie.”

RAMILLIES, or **Ramilles**, a village of Belgium, in the province of South Brabant, 16 m. S. by E. of Louvain, noted for a brilliant victory achieved here, May 23, 1706, by Marlborough at the head of English, Dutch, and Danish troops, over the French and Bavarians under Marshal Villeroi. France speedily surrendered almost all her possessions in the Spanish Netherlands, Marlborough expressing astonishment “that the enemy should give up a whole country with so many strong places without the least resistance.”

RAMISSERAM, or **Rameswar**, an island between Ceylon and the continent of India, at the W. extremity of the chain of rocks and sand banks, called Adam's Bridge, that stretch across from Ceylon and separate Palk strait from the gulf of Manaar. The island is of irregular shape, about 12 m. long and 6 m. broad. It is separated from the mainland by the Pamban passage, which has been improved and deepened by the British government, until its depth at low water now ranges from 11 to 14 ft. Several schemes for the construction of a ship canal across the W. end of the island itself are under consideration. The surface is generally low, and there are tracts of considerable extent covered by swamps. It is well watered, and there is a fresh-water lake nearly 3 m. in circumference. It has on its E. side, in lat. 9° 15' N., lon. 79° 20' E., a town of the same name, containing about 1,000 houses and a magnificent pagoda built of immense blocks of granite; its inhabitants are principally Brahmans. The island is looked upon as a place of great sanctity by the Hindoos, and pilgrimages are

undertaken to it from the most distant parts of India, the annual number visiting the great pagoda being estimated at 30,000.

RAM MOHUN ROY, rajah, a Hindoo scholar, born in the district of Burdwan, Bengal, about 1774, died near Bristol, England, Sept. 27, 1833. His family were strict Brahmans, but having studied the Koran he early renounced polytheism. In 1803, after the death of his father, Ram Mohun Roy published several pamphlets in the native and foreign languages, to show that the Brahmans had fallen away from their original faith, for which an attempt was made to deprive him of caste. He translated into Bengalee and Hindostanee the Vedanta, or body of Hindoo theology as contained in the Vedas, afterward prepared an abridgment of it, and in 1816 translated the abridgment into English. In conjunction with two other natives he published the "Bengal Herald," an English newspaper, and in 1820 published in English, Sanskrit, and Bengalee a series of selections from the New Testament, entitled "The Precepts of Jesus the Guide to Peace and Happiness." In this he advanced Unitarian opinions, which involved him for several years in controversy with Dr. Marshman and other missionaries. He believed in the divine mission of Christ, and considered Christianity consistent with Brahmanism. He distinguished himself by his exertions to abolish the practice of suttee, or female immolation. In 1830 he was accredited to the British court by the titular sovereign of Delhi, to make a representation of grievances, and was successful in his mission. He visited England twice, and was buried there.

RAMORINO, Girolamo (according to some, properly GIOVANNI PIETRO REMORINO), a military adventurer, born in Genoa about 1792, executed in Turin, May 22, 1849. He was a natural son of a French officer, entered the ranks of the French army, and in the campaign of 1809 against Austria served as a common soldier, and in that of 1812 against Russia as captain of artillery. In 1815 the emperor appointed him officer of ordnance, and after the second restoration he retired to Savoy. He was one of the leaders of the insurrection in Piedmont in 1821. After the failure of the movement he fled to France, and at the beginning of the Polish insurrection of 1830 hastened to Warsaw to offer his services. He was first made colonel, and then general of a corps with which he gained numerous advantages, and his success alone saved him from the condemnation of a court martial on account of his frequent disobedience of orders. After the fall of Warsaw he went to France. In 1834 he commanded in the invasion of Savoy planned by Mazzini. At the beginning of Charles Albert's second campaign, in 1849, Chrzanowski placed him at the head of the fifth division, with orders to prevent the advance of the enemy from Pavia. Ramorino, mistaking the design of the Austrians, left the N. bank of the Po unde-

fended and the direct road from Pavia to Turin open. The fatal issue of the battle of Novara, March 23, 1849, was the consequence. He was deprived of his command, arrested at Arona by the national guards, tried before a court martial on a charge of insubordination, and sentenced to be shot. He justified his course on the ground of the feebleness of his division, which rendered it impossible for him to prevent the advance of the Austrian army.

RAMSAY. I. Allan, a Scottish poet, born at Leadhills, Lanarkshire, Oct. 15, 1686, died in Edinburgh, Jan. 7, 1758. He was originally a wig maker in Edinburgh, and his first poem was written at the age of 26. He subsequently published on single or half sheets many poems on local or familiar topics. His first poem of considerable length was a continuation of King James's "Christ's Kirk on the Green" (1716). About this time he became a bookseller, being at the same time an industrious editor and author. In 1721 appeared a 4to edition of his collected poems. This was succeeded by his "Fables and Tales," "The Fair Assembly," "Health," a poem inscribed to the earl of Stair, and the "Tea Table Miscellany" (4 vols., 1724), a collection of songs, Scottish and English, which passed through 12 editions in a few years. His most important work was "The Gentle Shepherd" (1725), portions of which had appeared in his first volume of poems. He now removed to a larger shop, which soon became the resort of the wits and literary men of Edinburgh, and in which he established the first circulating library ever opened in Scotland. His last original work of importance was a collection of fables (1730). He retired from business in 1755. A complete edition of his poems, with a biography by George Chalmers, was published in 2 vols. 8vo in 1800 (new ed., with an essay on Ramsay's genius by Lord Woodhouslee, Paisley, 1874). **II. Allan**, a portrait painter, son of the preceding, born in Edinburgh in 1718, died in Dover, Aug. 10, 1784. He was a man of literary culture, settled in London, and was a visitor at the house of Dr. Johnson. Though raised to a momentary rivalry with Sir Joshua Reynolds, his works are not above mediocrity.

RAMSAY, Andrew Crombie, a British geologist, born in Glasgow, Jan. 31, 1814. He was early connected with the geological survey of Great Britain, of which he became a director in 1845, and director general in 1872. He was appointed professor of geology at University college, London, in 1848, and at the royal school of mines in 1851, which latter office he still holds (1875). He was president of the geological society in 1862-'3, and in 1872 succeeded Sir Roderick Murchison as director general of the museum of practical geology. His works include "The Geology of Arran" (1841); "Geology of North Wales" (1858); "Geological Map of England and Wales" (1859); "The Old Glaciers of North Wales and Switzerland"

(1860); "Physical Geology and Geography of Great Britain" (1863; 4th ed., 1875); and vol. v. of the "Geological Survey of Great Britain" (1856-'66), comprising "Geology of Wiltshire and Gloucestershire." He has in preparation (1875) a work on the formation of hills and valleys, to be entitled "Earth Sculpture."

RAMSAY, Andrew Michael, known as the chevalier de Ramsay, a Scottish author, born in Ayr in 1686, died in St. Germain-en-Laye, France, May 6, 1743. He was educated at the university of Edinburgh, afterward resided for six months with Fénelon at Cambrai, became a Roman Catholic, and was appointed tutor to the duke de Château-Thierry and afterward to the prince de Turenne. Subsequently he had charge for a year at Rome of the education of the two sons of the pretender. He revisited Scotland in 1725, and for several years was an inmate of the family of the duke of Argyll. Returning to France, he was intendant of the prince de Turenne till his death. His largest work is "On the Principles of Natural and Revealed Religion" (2 vols. 4to, Glasgow, 1749). His *Voyages de Cyrus* (2 vols. 8vo, Paris and London, 1727), by which he is best known, is a palpable imitation of the *Télémaque* of Fénelon. It was translated into English by Nathaniel Hooke. He also wrote a biography of Fénelon (the Hague, 1723), and one of Marshal Turenne (Paris, 1735), both translated into English.

RAMSAY, David, an American historian, born in Lancaster co., Pa., April 2, 1749, assassinated in Charleston, S. C., May 8, 1815. In 1773 he settled as a physician in Charleston. He took the field as a surgeon at the outbreak of the revolution, was a member of the South Carolina legislature, and of the privy council or council of safety, and after the capture of Charleston he was included among several inhabitants of that place who were held in close confinement at St. Augustine as hostages. From 1782 to 1786 he was a member of congress from the Charleston district, and for a year was president of that body. He was shot in the street by a lunatic, to whose insanity he had testified. In 1785 he published his "History of the Revolution in South Carolina," and in 1789 his "History of the American Revolution." Both were republished in Europe, and were translated into French. In 1801 he published a "Life of Washington," and in 1809 a "History of South Carolina" (2 vols. 8vo). His "History of the United States," from their settlement as English colonies to the close of 1808, was continued to the treaty of Ghent by the Rev. S. S. Smith and others (3 vols. 8vo). This was included in his "Universal History Americanized" (12 vols. 8vo, 1816-'19), purporting to give a historical view of the world from the earliest records to the 19th century. Among his minor works was a "History of the Congregational Church in Charleston" (1815).

RAMSAY, Edward Bannerman, a Scottish author, born at Balmain, Kincardineshire, Jan.

31, 1793, died in Edinburgh, Dec. 27, 1872. He graduated at St. John's college, Cambridge, in 1815, was a curate of the established church in Somersetshire for seven years, became minister of St. John's church in Edinburgh in 1830, and in 1841 dean of the Reformed Episcopal church in Scotland. He delivered in 1862 before the philosophical institute of Edinburgh two lectures on the "Genius and Works of Handel," and in 1866 two lectures on "Preachers and Preaching," which have been published in book form. His best known publication is his "Reminiscences of Scottish Life and Character" (Edinburgh, 1857), which in 1872 had passed through 19 editions. His "Manual of Catechising" (1859) has had 11 editions. He also published memoirs of Sir J. E. Smith (1827) and of Dr. Chalmers (1867); "Advent Sermons" (1850); "Diversities of Christian Character" (1858); "The Christian Life" (1859); "On the Canon Law of the Episcopal Church of Scotland as it stood in 1860" (1860); "Christian Responsibility" (1864); and "Pulpit Table Talk" (1868).

RAMSDEN, Jesse, an English instrument maker, born at Salterhebble, near Halifax, Yorkshire, in 1735, died in Brighton, Nov. 5, 1800. He was at first a cloth dresser, but in 1758 bound himself to an instrument maker in London, and he early opened a shop of his own. He improved the construction of the sextant so as to reduce the limit of error from 5' to 30". He married the daughter of Dollond, and acquired a part of Dollond's patent for achromatic telescopes. The telescopes erected by him at the observatories of Blenheim, Mannheim, Dublin, Paris, and Gotha were remarkable for the superiority of their object glasses. One of his most celebrated productions was a dividing machine of great perfection. By his will a large portion of his fortune was distributed among his workmen. He was a fellow of the royal society, and of the imperial academy of St. Petersburg.

RAMSES. See RAMESES.

RAMSEY. I. An E. county of Minnesota, bordered S. W. and S. by the Mississippi river; area, about 200 sq. m.; pop. in 1870, 22,886. It has an elevated surface, with prairies and forests. It is intersected by several railroads centring in St. Paul. The chief productions in 1870 were 54,321 bushels of wheat, 38,020 of Indian corn, 53,868 of oats, 9,015 of barley, 5,600 tons of hay, 1,500 lbs. of wool, and 91,185 of butter. There were 618 horses, 1,099 milch cows, 298 sheep, and 1,357 swine; 9 manufactories of carriages and wagons, 5 of furniture, 3 of dressed furs, 4 of machinery, 6 of saddlery and harness, 3 of sash, doors, and blinds, 3 of soap and candles, 3 of tin, copper, and sheet-iron ware, 1 tannery, 2 flour mills, 2 saw mills, and 4 distilleries. Capital, St. Paul, which is also the capital of the state.

II. A N. E. county of Dakota, recently formed and not included in the census of 1870; area, about 1,500 sq. m. Stump lake is in the S.

part, and the S. W. corner is occupied by a portion of Miniwakan or Devil's lake. The surface is rolling prairie.

RAMSGATE, a seaport of Kent, England, at the S. E. corner of the isle of Thanet, 67 m. E. by S. of London; pop. in 1871, 14,640. The older part of the town lies in a natural hollow, while the newer portions occupy the high ground on either side, have a fine sea view, and contain many handsome houses. The harbor is artificial, and nearly circular, comprising an area of 48 acres, and including a dry dock and ship railway. Ship building and rope making are carried on. Ramsgate is a dependency of Sandwich, and a fashionable watering place.

RAMUS, Joseph Marius, a French sculptor, born in Aix, June 19, 1805. He studied at the school of fine arts in Paris, and was sent to copy mediæval sculptures in the galleries of Florence. Among his works are statues of Lafontaine, Anne of Austria, St. John, Philippe of Champagne, and Judith. One of his finest is "David fighting Goliath." Many of his works are at Versailles and in the Luxembourg.

RAMUS, Peter (PIERRE DE LA RAMÉE), a French logician, born at Cuth, Picardy, in 1515 or 1502, killed in the massacre of St. Bartholomew at Paris, Aug. 24, 1572. At the age of 12 he entered the college of Navarre at Paris as a servant, and made rapid progress. When he presented himself for examination for the degree of master of arts in 1536, the subject of his exercise was: *Quæcumque ab Aristotele dicta esse commenticia esse* ("All that has been affirmed by Aristotle is a fabrication"), and he maintained it with so much skill that he was admitted to his degree. He afterward taught in the college of Ave Maria, and in 1543 published *Institutiones Dialecticæ et Animadversiones in Dialecticam Aristotelis*. These books were attacked by the officers of the university of Paris, and the author was represented as impious and seditious, and as aiming to destroy all science and religion under the pretence of assailing Aristotle. To settle the quarrel between the advocates of the rival systems of logic, Francis I. ordered a trial in which two of the judges were nominated by Ramus, two by Govea, his chief accuser, and one by the king. After a hearing, Ramus was condemned on March 1, 1544, as having "acted rashly, arrogantly, and impudently;" he was prohibited from teaching and his books were suppressed. Soon after he lectured on rhetoric at the college of Presles, and in 1545 was permitted to resume teaching in Paris. He began a course of mathematics, which was continued till 1551, when Henry II. appointed him professor of philosophy and eloquence. In 1561 he embraced Protestantism, and in July, 1562, he was forced to flee, but was offered by Charles IX. a refuge at Fontainebleau, his house having been pillaged and his library destroyed during his absence. In 1563 he returned to Paris, and for a time occupied the professor's

chair; but in 1568 he received permission to travel. He once more returned in 1571. His followers were called Ramists or Rameans. A catalogue of his works is contained in *Ramus, sa vie, ses écrits et ses opinions*, by Waddington-Kastus (8vo, Paris, 1855).

RAMUSIO, Giambattista, an Italian author, born in Treviso in 1485, died in Padua, July 10, 1557. He was secretary of the council of ten in Venice, travelled as ambassador through France, Switzerland, and Italy, and was author of *Raccolta di navigazioni e viaggi* (3 vols., 1550-'59), a collection of voyages and travels in ancient and modern times. He left materials for a fourth volume, but they were destroyed by fire in 1557. The best edition is that of 1606.

RANCÉ, Armand Jean Le Bouthillier de, reformer of the monastery of La Trappe, born in Paris, Jan. 9, 1626, died Oct. 27, 1700. He was a godson of Cardinal Richelieu, and at the age of 12 published an edition of Anacreon, with notes and comments. Though ordained a priest in 1651, he led a dissipated life, and was an assiduous visitor at the hôtel Rambouillet, where he fell in love with the duchess de Montbazou. After her death he submitted himself to severe penances, gave his property to the poor, and resigned all his benefices except the abbey of La Trappe, to which he retired in 1662. Impressed with the necessity of a reform in monastic life, he went to Rome in 1664 to obtain from the pope permission to enforce in France the rules of the former "strict observance of Cîteaux." He failed in his mission, but on his return in 1666 he introduced the most rigorous regulations into his own community. In 1683 he published a treatise *De la sainteté et des devoirs de la vie monastique*, and in 1690 assumed the spiritual direction of the convent of Les Claires, a female community dependent on that of La Trappe, and composed his *Réflexions sur les quatre évangélistes*. In 1695, having brought on a severe disease by his austerities, he resigned his abbacy and remained a private monk in the convent, redoubling his penances, and finally breathing his last upon a bed of straw and ashes. His life was written by his contemporaries Maupeau, Marsollier, and Lenain de Tillemont, by Chateaubriand (Paris, 1844), and by C. Butler (London, 1814).

RANDALL, Samuel Jackson. See supplement.

RANDOLPH, the name of counties in eight of the United States. **I.** A N. E. county of West Virginia, drained by the sources of the Monongahela river; area, about 1,200 sq. m.; pop. in 1870, 5,563, of whom 103 were colored. A range of the Alleghanies runs along its E. border, and several parallel ranges extend within its limits; the soil in the valleys is fertile. Coal, iron, salt, limestone, and other minerals abound. The chief productions in 1870 were 8,969 bushels of wheat, 59,758 of Indian corn, 33,237 of oats, 7,298 tons of hay, 17,706 lbs. of wool, 90,840 of butter, and 3,603 gallons of

sorghum molasses. There were 1,525 horses, 1,970 milch cows, 6,503 other cattle, 8,523 sheep, and 2,834 swine. Capital, Beverly. **II.** A central county of North Carolina, drained by Deep river and by the Uharie, a tributary of the Yadkin; area, 725 sq. m.; pop. in 1870, 17,551, of whom 2,606 were colored. The surface is rolling and the soil generally fertile. The chief productions in 1870 were 137,427 bushels of wheat, 264,924 of Indian corn, 95,681 of oats, 18,880 of Irish and 23,125 of sweet potatoes, 24,399 lbs. of tobacco, 26,050 of wool, 121,618 of butter, and 4,346 tons of hay. There were 2,844 horses, 772 mules and asses, 4,787 milch cows, 839 working oxen, 6,290 other cattle, 17,101 sheep, and 23,387 swine. Capital, Ashborough. **III.** A S. W. county of Georgia, separated from Alabama by the Chattahoochee, intersected by Pataula creek, and drained by branches of Flint river; area, about 400 sq. m.; pop. in 1870, 10,561, of whom 5,477 were colored. It has a nearly level surface, and a very fertile soil in the river bottoms. It is traversed by the Southwestern railroad of Georgia. The chief productions in 1870 were 184,940 bushels of Indian corn, 25,457 of sweet potatoes, 5,748 bales of cotton, 2,215 lbs. of wool, and 9,165 gallons of molasses. There were 574 horses, 962 mules and asses, 1,553 milch cows, 2,803 other cattle, 1,143 sheep, and 9,540 swine. Capital, Cuthbert. **IV.** An E. county of Alabama, bordering on Georgia, intersected by the Tallapoosa river; area, about 600 sq. m.; pop. in 1870, 12,006, of whom 1,641 were colored. It has an uneven surface and a generally fertile soil. Gold is found. The chief productions in 1870 were 48,587 bushels of wheat, 264,448 of Indian corn, 20,707 of oats, 37,758 of sweet potatoes, 2,246 bales of cotton, 7,667 lbs. of tobacco, 13,262 of wool, 125,066 of butter, and 8,188 gallons of cane and 4,804 of sorghum molasses. There were 1,313 horses, 845 mules and asses, 3,062 milch cows, 1,751 working oxen, 5,047 other cattle, 7,485 sheep, and 14,819 swine. Capital, Wedowee. **V.** A N. E. county of Arkansas, bordering on Missouri and drained by branches of Black river; area, about 850 sq. m.; pop. in 1870, 7,466, of whom 357 were colored. Its surface is generally level and the soil fertile. It is intersected by the Cairo and Fulton railroad. The chief productions in 1870 were 16,733 bushels of wheat, 265,990 of Indian corn, 18,293 of oats, 11,130 lbs. of tobacco, 7,643 of wool, and 57,450 of butter. There were 757 horses, 1,472 milch cows, 2,706 other cattle, 2,507 sheep, and 8,658 swine. Capital, Pochontas. **VI.** An E. county of Indiana, bordering on Ohio, and drained by White, Mississinewa, and Whitewater rivers; area, about 400 sq. m.; pop. in 1870, 22,862. It has an undulating surface and fertile soil. It is intersected by several railroads. The chief productions in 1870 were 535,003 bushels of wheat, 740,051 of Indian corn, 147,992 of

oats, 10,088 of flax seed, 9,208 tons of hay, 73,019 lbs. of wool, 349,327 of butter, and 36,914 gallons of maple molasses. There were 8,485 horses, 6,094 milch cows, 8,571 other cattle, 25,154 sheep, and 32,590 swine; 5 manufactories of carriages and wagons, 9 of furniture, 2 of wagon material, 1 of woollen goods, 4 tanneries, 7 flour mills, and 19 saw mills. Capital, Winchester. **VII.** A S. W. county of Illinois, separated from Missouri by the Mississippi river, intersected by the Kaskaskia, and drained by several small streams; area, about 500 sq. m.; pop. in 1870, 20,859. It has an undulating and hilly surface and a generally fertile soil. It is intersected by the St. Louis, Belleville, and Southern Illinois, and the Chester and Tamaroa railroads. The chief productions in 1870 were 1,031,472 bushels of wheat, 510,080 of Indian corn, 414,487 of oats, 107,049 of Irish and 11,362 of sweet potatoes, 11,097 tons of hay, 3,572 lbs. of tobacco, 35,731 of wool, 109,184 of butter, and 42,345 gallons of sorghum molasses. There were 6,972 horses, 1,209 mules and asses, 4,619 milch cows, 5,351 other cattle, 12,180 sheep, and 24,590 swine; 2 manufactories of agricultural implements, 19 of carriages and wagons, 10 of saddlery and harness, 3 of woollen goods, 3 breweries, 10 flour mills, and 4 saw mills. Capital, Chester. **VIII.** A N. county of Missouri, intersected by the E. fork of Chariton river and drained by several other streams; area, about 450 sq. m.; pop. in 1870, 15,908, of whom 2,134 were colored. It has a nearly level surface and a very fertile soil. It is intersected by the St. Louis, Kansas City, and Northern railroad. The chief productions in 1870 were 82,538 bushels of wheat, 22,361 of rye, 594,372 of Indian corn, 209,013 of oats, 7,929 tons of hay, 873,776 lbs. of tobacco, 63,623 of wool, 150,737 of butter, 22,435 of honey, and 15,169 gallons of sorghum molasses. There were 7,155 horses, 2,203 mules and asses, 4,380 milch cows, 7,133 other cattle, 21,770 sheep, and 25,714 swine; 3 flour mills, and 6 saw mills. Capital, Huntsville.

RANDOLPH, Edmund, an American statesman, son of John and nephew of Peyton Randolph, born in Virginia, Aug. 10, 1753, died in Frederick co., Va., Sept. 12, 1813. He is said to have been disinherited by his father, who was an intense royalist. In 1775 he served on the staff of Washington. He was a delegate to the Virginia convention in May, 1776, and from 1779 to 1783 he was a member of the continental congress. In 1787 he was a member of the constitutional convention, and introduced what was called the "Virginia plan." He refused to sign the constitution, though he afterward advocated its adoption in the Virginia convention. In 1788 he was governor of Virginia, and in 1789 was appointed attorney general of the United States. In January, 1794, he succeeded Jefferson as secretary of state; but having been accused of an intrigue with the French envoy, he resigned in

August, 1795. He published "A Vindication" (Philadelphia, 1795).

RANDOLPH, John, of Roanoke, an American orator, born at Cawsons, Chesterfield co., Va., June 2, 1773, died in Philadelphia, June 24, 1833. He was educated at Princeton, at Columbia college, New York, and at the college of William and Mary, and studied law at Philadelphia, but never practised. In 1799 he was elected a representative in congress, and soon became conspicuous, in the language of Hildreth, as "a singular mixture of the aristocrat and the Jacobin." He was reelected in 1801, and was made chairman of the committee of ways and means. In 1803, as chairman of a committee, he reported against a memorial from Indiana for permission to introduce slaves into that territory in spite of the prohibition of the ordinance of 1787, which he pronounced to be "wisely calculated to promote the happiness and prosperity of the northwestern country." In 1804 he was chief manager in the trial of Judge Chase, impeached before the senate. (See CHASE, SAMUEL.) In 1806 he assailed President Jefferson and his supporters with great virulence. He attacked Madison's administration, and opposed the declaration of war against Great Britain in 1812. His opposition caused his defeat at the next election. He was reelected in 1814, and again in 1818, having declined to be a candidate in 1816. In the congress of 1819-'20 he opposed the Missouri compromise, stigmatizing the northern members by whose coöperation it was carried as "doughfaces," an epithet adopted into the political vocabulary of the United States. In 1822, and again in 1824, he visited England. From 1825 to 1827 he was a senator of the United States, and during that time fought a duel with Mr. Clay. (See CLAY, HENRY.) He supported Gen. Jackson for president in 1828. In 1829 he was a member of the convention to revise the constitution of Virginia, and in 1830 was appointed minister to Russia; but soon after his reception by the emperor Nicholas, he departed abruptly for England, where he remained for nearly a year, and returned home without revisiting Russia. He was again elected to congress, but was too ill to take his seat. Exhausted with consumption, he died in a hotel at Philadelphia, whither he had gone on his way to take passage again across the ocean. During his life his speeches were more fully reported and more generally read than those of any other member of congress. He was tall and slender, with long, skinny fingers, which he was in the habit of pointing and shaking at those against whom he spoke. His voice was shrill and piping, but under perfect command and musical in its lower tones. His invective, sarcasm, and sharp and reckless wit made him a terror to his opponents in the house. At the time of his death he owned 318 slaves, whom by his will he manumitted, bequeathing funds for their settlement and maintenance in a free state. His "Letters

to a Young Relative" appeared in 1834.—See "Life of John Randolph," by Hugh A. Garland (2 vols. 8vo, New York, 1850).

RANDOLPH, Peyton, an American patriot, president of the first congress, born in Virginia in 1723, died in Philadelphia, Oct. 22, 1775. He was the second son of Sir John Randolph, and after graduating at the college of William and Mary went to England and studied law at the Temple. In 1748 he was appointed king's attorney general for the colony, was chosen a member of the house of burgesses, and was chairman of a committee to revise the laws of the colony. In 1764 he drew up the address of the burgesses to the king against the passage of the stamp act. In 1765, after that act became a law, Randolph with other proprietors of large estates opposed Patrick Henry's celebrated five resolutions. (See HENRY, PATRICK.) In the same year Virginia forwarded to England petitions similar to those adopted by the congress, with an address to the king written by Randolph. In 1766 Randolph was made speaker of the house of burgesses, resigning about the same time his office of attorney general. In the measures of opposition to the English government he now took a conspicuous part. He was a member of the committee of vigilance appointed to obtain the most accurate intelligence of all acts of parliament affecting the rights of the colonies, and to open a correspondence with the other colonies. In August, 1774, he presided in the convention at Williamsburg, and was one of the delegates elected to the continental congress. On the assembling of that body in Philadelphia in September, he was unanimously elected its president, but in consequence of ill health held that post only five or six weeks. In 1775 he presided over the second convention of Virginia at Richmond, was elected again as a delegate to congress, and when that body met at Philadelphia on May 10, 1775, was reelected president; but the duties of speaker of the house of burgesses recalling him to Virginia, he was succeeded by John Hancock. He died suddenly of apoplexy.

RANDOLPH MACON COLLEGE, an institution of learning at Ashland, Hanover co., Va., 16 m. N. of Richmond, on the Richmond, Fredericksburg, and Potomac railroad. It was founded by a resolution of the Virginia conference of the Methodist Episcopal church in 1827, the charter was obtained in 1830, and the college began work in Mecklenburg co., Va., near the North Carolina border, in 1832. In 1852 an endowment of \$100,000 was secured, but this was lost for the most part during the civil war. In 1866 the college was removed to its present site. The course of study is distributed into separate schools, of Latin, Greek, English, &c., the principal schools being arranged in four courses of one year each. Degrees are conferred for graduation in each school; for graduation in a certain number of schools the degree of B. S. or A. B. is given, and for gradu-

ation with distinction that of A. M. There is a school of Biblical literature and oriental languages for students preparing for the ministry, to whom instruction in all the schools is free. A diploma is conferred for graduation in Biblical literature. In 1875 the college had 10 professors and tutors and 235 students.

RANGOON, a seaport and the capital of British Burmah, in Pegu, on the left bank of the E. branch of the Irrawaddy, known as the Rangoon, about 26 m. from the sea, in lat. $16^{\circ} 46' N.$, lon. $96^{\circ} 17' E.$; pop. in 1871, 96,952. The houses of the town are somewhat unequally distributed, in narrow but clean and well paved streets, over a space about a mile long, parallel to the river, and extending three quarters of a mile inland. There are several Buddhist pagodas, one Baptist, two Episcopal, and two Roman Catholic churches, and a number of schools. It is the centre of the American Baptist missions in Burmah, connected with which are a theological seminary, college, and printing office. The harbor is capable of receiving vessels of 1,200 tons, and the tide rises 18 to 25 and even 30 ft. Ship building is an important industry. The principal export is rice; next in the order of values come timber, raw cotton, and petroleum. The East Indian trade of Rangoon is mostly with Calcutta, but also extends to Madras ports and the Straits Settlements. There are five lighthouses on the Burmese coast to guide vessels to the port. The town is fortified and garrisoned. It has two markets, a recorder's court, and an English newspaper.—Rangoon was founded by the Burmese conqueror of Pegu in 1755. In 1852 it fell into the hands of the British, who have since retained it. In 1853 and 1855 it was greatly devastated by fire.

RANKE, Leopold von, a German historian, born at Wiehe, near Naumburg, Dec. 21, 1795. In 1818 he became principal teacher of the gymnasium of Frankfort-on-the-Oder. In 1824 appeared at Berlin his *Geschichte der romanischen und germanischen Völker von 1494–1555*. He was made professor of history in Berlin in 1825, and soon after was sent by the Prussian government to search for historical materials in the archives of Vienna, Venice, Rome, and Florence. The first results of his labors appeared in the 1st volume (embracing the history of the Ottomans and the Spanish monarchy) of his *Fürsten und Völker von Südeuropa im 16ten und 17ten Jahrhundert* (1827). In 1829 he published *Die serbische Revolution*, in 1831 *Ueber die Verschwörung zu Venedig im Jahre 1688*, and in 1837 *Vorlesungen zur Geschichte der italienischen Poesie*. His work *Die römischen Päpste, ihre Kirche und ihr Staat* ("The Popes of Rome, their Church and State," 3 vols., Berlin, 1834-'6), forming the 2d, 3d, and 4th volumes of the *Fürsten und Völker von Südeuropa*, &c., was translated into English by Mrs. Austin in 1840; by Scott, with an introductory essay by Merle d'Aubigné, in 1846; and by E. Foster in 1848.

A sixth edition of it was published in 1874 with the title *Die römischen Päpste in den letzten vier Jahrhunderten* (3 vols., Leipsic), and a seventh in 1875. In 1832 he began the *Historisch-politische Zeitschrift* (vol. i., Hamburg, 1832; vol. ii., Berlin, 1833-'6), which, being decried as illiberal, was discontinued in 1836. His *Deutsche Geschichte im Zeitalter der Reformation* ("History of Germany in the Time of the Reformation," 6 vols., Berlin, 1839-'47), in which he gave an account of the rise of Protestantism, was translated into English by Mrs. Austin (5th ed., 1874). It was followed by *Neun Bücher preussischer Geschichten* (3 vols., 1847-'8), for aid in writing which the Prussian archives were for the first time opened. This work has been translated by Sir A. and Lady Duff Gordon, under the title of "Memoirs of the House of Brandenburg, and History of Prussia during the 17th and 18th Centuries" (1849). He has also written *Jahrbücher des deutschen Reichs unter dem sächsischen Hause* (3 vols., 1837-'40); *Französische Geschichte, vornehmlich im 16ten und 17ten Jahrhundert* (5 vols., Stuttgart, 1852-'5), which contains an account of Protestant struggles in France; *Englische Geschichte im 16ten und 17ten Jahrhundert* (7 vols., Berlin and Leipsic, 1859-'68; English translation, "A History of England, principally in the Seventeenth Century," 6 vols., Oxford, 1875); *Geschichte Wallensteins* (Leipsic, 1869); *Ursprung des siebenjährigen Krieges* (1871); and *Genesis des preussischen Staats, und Aus dem Briefwechsel Friedrich Wilhelm's IV. mit Bunsen* (1873). An edition of his complete works, to comprise 36 vols., is in progress (29 vols., 1867-'74).—His brother **FRIEDRICH HEINRICH**, born in 1797, from 1842 chief councillor of the Protestant consistory of Munich, is the author of *Untersuchungen über den Pentateuch* (2 vols., Erlangen, 1834-'40), *Zeugnis von Christo* (2 vols., 1845-'8), *Das Leben in Christo* (Frankfort, 1852), &c.

RANKIN, a central county of Mississippi, bordered W. and N. W. by Pearl river and drained by its branches; area, about 800 sq. m.; pop. in 1870, 12,977, of whom 7,273 were colored. Its surface is covered with pine forests, and its soil is generally fertile. It is intersected by the Vicksburg and Meridian railroad. The chief productions in 1870 were 217,708 bushels of Indian corn, 5,996 of oats, 13,360 lbs. of rice, 3,279 of wool, and 8,705 bales of cotton. There were 1,327 horses, 1,083 mules and asses, 3,088 milch cows, 1,315 working oxen, 5,023 other cattle, 4,799 sheep, and 13,239 swine. Capital, Brandon.

RANKINE, William John Macquorn, a Scottish physicist, born in Edinburgh, July 5, 1820, died in Glasgow, Dec. 24, 1872. He attended scientific classes in the university of Edinburgh, and when 22 years of age published "An Experimental Inquiry into the Advantages attending the Use of Cylindrical Wheels." In 1843 he was elected an associate of the institution of civil engineers. In 1849 he pub-

lished an investigation of the theory of molecular vortices, and was elected a fellow of the royal society of Edinburgh, to which in 1850 he presented a paper on the mechanical action of heat, especially in gases and vapors, published in 1851. In the winter of 1850-'51 he took up his residence in Glasgow, and in 1852 read to the philosophical society a paper on transformation of energy. In 1855 he was chosen a fellow of the royal society of London, and delivered a course of lectures on the mechanical action of heat in the university of Glasgow, and was elected regius professor of civil engineering there. He published "Manual of Applied Mechanics" (1858); "Manual of the Steam Engine and other Prime Movers" (1859); "Civil Engineering" (1862); "Useful Rules and Tables" (1866); "Cyclopædia of Machine and Hand Tools" (1869); and "Manual of Machinery and Millwork" (1869).

RANSOM, an E. county of Dakota, recently formed and not included in the census of 1870; area, about 1,800 sq. m. The N. part is watered by the Sheyenne river, a tributary of the Red, and the S. W. corner by the Dakota. The surface consists of rolling prairies.

RANTOUL, Robert, jr., an American statesman, born in Beverly, Mass., May 13, 1805, died in Washington, D. C., Aug. 7, 1852. He graduated at Harvard college in 1826, was admitted to the Essex bar in 1827, and practised in South Reading till 1832, when he removed to Gloucester, which town he represented in the legislature in 1834-'7. He exerted himself for the abolition of capital punishment, and his report on that subject is still one of the standard authorities of the opponents of the practice. In 1837 he was appointed a member of the Massachusetts board of education. In 1838 he removed to Boston, in 1843 was appointed by President Tyler collector of the port, and in 1845 United States district attorney. In 1851 he filled a part of the unexpired term of Daniel Webster in the United States senate; and in the session of 1851-'2 he sat in the house of representatives, having been elected as a freesoiler. His speeches and writings, with a memoir, appeared in 1854.

RANUNCULUS (Lat., a little frog, some of the species growing in wet places where frogs abound), the botanical name of a large genus of plants, the common species of which are popularly known as buttercup, kingcup, or crowfoot. The genus gives its name to a large family, the *ranunculaceæ*, which comprises plants widely differing in their external appearance, many of which are among the best known and most showy wild and garden plants; the anemones, columbines, larkspurs, aconites, peonies, and others belong here. In modern systematic works upon botany this family is placed at the head of the list, and is the one with which the student first makes acquaintance, examples being found almost everywhere; the flowers are usually rather large and the structure distinct and easily made out. The

ranunculaceæ consist mainly of herbs (rarely undershrubs or woody climbers) with a colorless, acrid juice; they are polypetalous, or when the petals are absent the calyx is colored like, and is often mistaken for, the corolla; the stamens numerous, and the pistils (usually more than one) distinct (rarely somewhat united), one-celled, and one- to many-ovuled. The leaves when not radical are alternate, or in a few genera opposite, often much divided,

Ranunculus—Section of Flower.

and have sheathing petioles. In *ranunculus* itself there are five sepals and five flat petals, each with a little scale or pit at its base; numerous pistils, which ripen into a head of mostly flattened, one-seeded fruits or akenes; sometimes the sepals and petals are only three, or the petals more than five, and sometimes white instead of the usual yellow. There are about 160 species, which are distributed all over the world; in the eastern states there are some 20 species, including four introduced from Europe, and in the far west several others. Some are truly aquatic, others abound in muddy and swampy places; one is found only at the seaside or by the shores of the great lakes, and others are common weeds. All have an acrid juice, which in some is so powerful as to blister readily, and was formerly used as a vesicant; the leaves are said to be used by the professional beggars of London to keep up ulcers with which to excite sympathy. This acidity is dissipated in drying; one of the most active, very common in the meadows in the older states, is cut in large quantities with the grass, and is eaten with the hay, though animals at pasture avoid it in the fresh state. The species common as meadow weeds are the bulbous and the tall buttercups; the first named (*R. bulbosus*), more abundant in New England than elsewhere, is readily distinguished by the bulb-like base to the stem, and its very large flowers, more than an inch broad, and of a very deep shining yellow, blooming from May to July. Tall buttercup (*R. acris*) is more widely distributed and grows twice as high as the preceding, in rich soil being 3 ft. or more tall; its stem is not bulbous, and its smaller and paler flowers appear in June and continue till August and later. There are double varieties of both these species, common in gardens as double buttercups, the *boutons d'or* of the French. The creeping crowfoot or buttercup (*R. repens*) is a very common species, forming long runners which root at every joint; it is extremely variable, and often found without runners; it is a native, and somewhat troublesome in moist meadows and pastures. The yellow water buttercup (*R. multifidus* or *R. Purshii* of the older books) has its leaves very much dissected into filiform divisions, and bears

a large bright yellow flower; its handsome foliage makes it an excellent plant for an aquarium. The remaining natives are only of botanical interest.—Among the exotic species cultivated in gardens is *R. aconitifolius*, which grows 2 ft. or more high, and has large white

Garden Ranunculus (*Ranunculus Asiaticus*).

flowers; there is a double form of it, with flowers like minute camellias, which bears the fanciful name of "fair maids of France." Some other hardy species are grown in European gardens, but rarely in ours.—The Asiatic ranunculus (*R. Asiaticus*) ranks as a florist's flower. The roots, which are imported in autumn by the seedsmen with Holland bulbs, are in small clusters, fleshy, an inch or more long, and apparently without signs of life; they are not hardy generally in the northern

states, and if planted in the garden must be well covered; they are often cultivated in pots, in the same manner as bulbs, and give large very double flowers, 2 in. across, and of a great variety of colors.

RANZANI, Camillo, an Italian naturalist, born in Bologna, June 22, 1775, died there, April 23, 1841. He was educated at Bologna, and at the age of 22 became professor of philosophy in the university of Fano, where he received holy orders, and taught till 1798. Political disturbances compelling him to return to Bologna, he was appointed keeper of the botanic garden, and in 1803 professor of natural history in the university, of which he became rector in 1824. His chief work is his uncompleted *Elementi di zoologia* (10 vols., 1819 et seq.).

RANZ DES VACHES, the name applied to certain simple melodies played by the mountaineers of Switzerland upon the Alpine horn, which are identified with the scenes and pursuits of pastoral life. The term (in German *Kuhreigen* or *Kuhreihen*) means literally cow rows, and the musical call of the herdsman is so named from the fact that the cattle in answering it move toward him in a row, preceded by those wearing bells. The character of these melodies, which are scarcely such in fact, as they are not governed by the ordinary rules of music, varies in different parts of Switzerland. They are in general without words. A collection of the various *Ranz des Vaches* and other Swiss airs was published at Bern in 1818 under the title of *Sammlung von schweizer Kuhreihen und Volksliedern*. They are also incorporated in the *Allgemeines schweizer Liederbuch* (1851).

RAOUL-ROCHETTE. See **ROCHETTE**.

RAPE (law French, *rapt*; law Latin, *raptus*), the violation or carnal knowledge of a woman, forcibly and against her will. Early English statutes, which have perhaps in some of the United States the force of common law, extend this to the case of a woman child under the age of 10 years carnally known either with or against her will. Every civilized nation, ancient and modern, has declared by its criminal code its abhorrence of this offence, and affixed to its commission the severest punishments. By the Mosaic law, to ravish a damsel who was betrothed to another was a crime punishable with death; and in case of one not betrothed the offender was compelled to take the damsel to wife and pay her father a fine of 50 shekels. By the civil law rape was punishable with death and confiscation of goods. Unlike our law, however, the civilians made no distinction between rape as defined by us, of which force is the characteristic element, and seduction without force, of which the common law takes no cognizance; and by the civil law the unlawful carnal knowledge of a woman with her consent was subject to the same severity of punishment as if obtained forcibly and against her will. This, we are told, was because the Roman law entertained so high an opinion of the virtue and chastity of woman, that it would not presume her to be capable of a violation of those qualities, unless induced thereto by the evil arts and solicitations of man; and in order to secure her the more effectually from the danger of these, it made such a violation of chastity, however consummated, equally a crime in him, and visited its penalties upon him alone. By the Saxons rape was also esteemed a felony and punished with death, though the woman ravished (if single) might redeem the offender from execution if she were willing to accept him as her husband, and he were willing to be so redeemed. But William the Conqueror, probably deeming the punishment of death too severe, altered it to castration and loss of the eyes. In the reign of Edward I. the law was still further modified, and rape was declared to be, and was punished as, a misdemeanor only; but the consequences of this amelioration proving disastrous and inducing a fearful increase of the crime, 10 years afterward, during the same reign, it was restored to the rank of felony and punished as before with death. By 9 George IV. it was made a non-capital felony, and is now punishable by imprisonment with hard labor for not less than two years. In the United States, although by statute the punishment varies somewhat in different states, it is by all treated as felony and punished with imprisonment for life or for a term of years.—It was for a long time an unsettled question what was requisite to constitute this offence, and proof of the full accomplishment of the act was once considered indispensable in order to secure a conviction. As far as the wrong and outrage to the individual is concerned,

the crime is perhaps equally entire where the offence is imperfectly committed. But the physical completion of the offence is not now necessary, in law, to complete the guilt of the offender; for it is not the degree of gratification to the lust of the ravisher which gauges the degree of criminality, but the injury done to the person and feelings of the victim, and the dastardly violation of that modesty and sense of delicacy which nature has implanted in the female heart. Force is a necessary element, and the offence must be perpetrated against the will of the party ravished. Though the woman at first consent, yet if she is afterward forced, or if her consent is obtained through duress or fear of death, it is equally a rape; and so careful is our law of the rights and safety of all classes and persons, that even a common prostitute may be the subject of a rape, though by the civil law she could not be. But fraud is not equivalent to force, and in the case of Jackson, who accomplished his purpose by personating the woman's husband during his absence, it was held, after careful consideration by the judges, that he could not be convicted of rape, but simply of an assault. It has been made a question whether sexual intercourse with a female *non compos mentis* should not be held to be rape, on the ground of her inability to give consent; but the authorities are to the contrary where no force is employed and such consent as she is capable of is given. A husband cannot commit a rape upon his wife, for by the marriage contract she yields herself to him, and she cannot afterward retract her assent; but if he is present, and aids in prostituting her to another against her will, he becomes thereby equally guilty with the principal, and is liable to the same punishment as the actual perpetrator of the outrage. An infant under 14 years of age is presumed in law, on the ground of a supposed imbecility of body if not of mind, to be incapable of committing a rape; and though as to other felonies the maxim *malitia supplet aetatem* holds, it is not so as regards this offence. An infant may, however, where the mischievous intention and capacity are evident, become a principal in the second degree, or suffer conviction for an assault with intent.—The party ravished is a competent witness against the accused; but her credibility is a matter for the consideration of the jury. If unsupported by other direct testimony, it must depend on concurrent circumstances for confirmation; as “for instance,” says Sir Matthew Hale, “if the witness be of good fame, if she presently discovered the offence, made pursuit after the offender, showed circumstances and signs of the injury, whereof many are of that nature that only women are the most proper examiners and inspectors, if the place where the fact was done was remote from people, inhabitants, or passengers, if the offender fled for it; these and the like are concurring evidences to give greater probability to her testimony, when

proved by others as well as herself.” In charges of this nature the courts are compelled to proceed with the utmost caution and care and to require convincing evidence of guilt before convicting the accused; for, as Sir Matthew Hale further remarks: “It is true rape is a most detestable crime, and therefore ought severely and impartially to be punished with death; but it must be remembered that it is an accusation easily made and hard to be proved, and harder to be defended by the party accused, though never so innocent;” and he then proceeds to state several singular cases which came under his own judicial observation, and in which innocent men falsely and maliciously accused of this crime narrowly escaped conviction. The defendant may impeach the character of the prosecutrix by general evidence, but particular acts of misconduct or immorality are inadmissible. As regards the testimony of children under 10 years of age, upon whom this offence has been committed, it is admissible where the witness is old enough and has sufficient instruction and intelligence to understand the relations of good and evil, and the nature of an oath; but, like that of older complainants, its credibility depends upon similar supporting circumstances.—As in other felonies, there may be accessories before and after the fact; but all persons actually present, aiding and abetting its commission, are principals, and are liable to the same punishment as that awarded to the actual perpetrator of the outrage. An attempt to commit a rape, which is usually indicted as “an assault with an attempt,” &c., is a high misdemeanor, and is severely punished by the laws of the various United States.

RAPE (Lat. *rapum*), a cruciferous plant cultivated from very early times for the oil contained in its seeds, and as a forage plant. It belongs in the genus *brassica*, sufficiently described under **MUSTARD**; some botanists place the turnip and rape as distinct species (*B. napus* and *B. rapa*), but the best authors now regard both as varieties of *B. campestris*, a variable plant found throughout Europe and Russian Asia, and differing from others of the genus in having its stem leaves sessile and auricled, or produced at base into two rounded lobes; the lower leaves pinnately divided, slightly glaucous, and usually rough with stiff hairs; flowers bright yellow. Though not botanically distinct from the turnip, the two are quite unlike in their uses; the turnip having been cultivated for centuries with a view to the development of the root to the neglect of all other parts, while in the rape, the greatest amount of seeds being desirable, no regard has been had to the root, which remains small and in its natural condition. The plant is an annual, but some of the forms of it are treated like biennials, being sown in autumn to perfect itself the following summer. It is an important plant in English agriculture, where it is cultivated for its herbage, of which on rich

land it yields an enormous amount, the plant standing 4 ft. high; domestic animals generally are fond of it, and it is especially useful for sheep, which are allowed to feed it off, and thus enrich the land; it is sometimes ploughed under as a green fertilizer. In this country

Rape (*Brassica campestris*, var. *rapa*).

rape has been but little cultivated; the winters in the northern states are too severe for the fall-planted kinds, but the early or German rape, sown in May, has been satisfactorily tried by some sheep raisers. In Europe it is grown in gardens as a salad plant and pot herb, being eaten young in the same manner as mustard. As a forage plant it is sown broadcast, the stems being more succulent if the plants are crowded; but when grown for its seeds, the young plants are raised in a seed bed, and when large enough are set in the field in rows the same as cabbages; the yield of seed varies from 20 to 40 bushels to the acre. The seeds closely resemble those of the turnip, but are somewhat larger; they yield about 33 per cent. of oil, which, when freed from the mucilage it contains, is used as a lubricator, for illumination, for dressing leather, in the manufacture of woollen cloths, for soap making, and for other purposes; it is also called colza oil, a name more especially given to that derived from a sub-variety called *B. campestris oleifera*. The mass left after the expression of the oil, known as rape cake, is a considerable article of commerce in Europe; its composition is, in 100 parts, water 15, ash 7.4, albuminoids 18.3, carbohydrates 33.5, crude fibre 15.8, fat, &c., 10; it is a powerful manure, which acts promptly, and is used either in compost, or ground fine and drilled in with the seed; it is especially valuable for turnips and wheat.

RAPHAEL (RAFFAELLE SANZIO, or SANTI D'URBINO), an Italian painter, born in Urbino, April 6, 1483, died in Rome, April 6, 1520. He belonged to a family of artists, and his father, Giovanni Santi (whose life has been written

by Count Pompeo Gherardi, 1875), was his first instructor. At the age of 12 he was placed in the school of Perugino, and remained with him until near his 20th year, assisting him, but attempting nothing which can be authenticated as his own until about 1500. After leaving the school of Perugino, he worked for about a year in Perugia, producing the "Marriage of the Virgin," now in the Brera at Milan, and well known by Longhi's engraving; "The Knight's Dream," now in the British national gallery; the "Agony in the Garden," and "St. Michael and St. George," all executed in what is known as his first or Peruginian manner. In 1504 Raphael visited Florence for the first time. The compositions by Leonardo da Vinci and Michel Angelo, known as the "Battle for the Standard" and the "Cartoon of Pisa," had recently been opened to public inspection, and to their influence may be attributed the new era which thenceforth commences in his development. He returned in the same year to Perugia, and for several months was employed in painting altarpieces, after which he revisited Florence, where he remained until the middle of 1508. During this period he painted about 30 pictures, the latest essentially after the style of the Florentines, and particularly of Leonardo da Vinci. Preëminent among them were those testifying his devotion for the Virgin, to whom in after life he dedicated a chapel in Rome. "The mere collection of all the Virgins painted or even designed by Raphael," says Quatremère de Quincy, "and the detail of the variations which he introduced into his compositions, would form an abridged history of his genius." The *Madonna del granduca*, now in the Pitti palace, painted either during his first visit to Florence or in the early part of his longer sojourn there, represents the highest perfection of which Perugino's type was capable. Immediately succeeding this in date were the "Madonna of the Palm Tree," now in the Ellesmere collection; the *Madonna del cardellino* (of the goldfinch), in the Florentine gallery, so called because the little St. John is presenting a goldfinch to the infant Christ; and the picture in the Louvre known as *La belle jardinière*, in which the Madonna is sitting with the two children in the midst of a beautiful landscape. To this Florentine period belong also the "St. Catharine" in the British national gallery, the two little "St. Georges" in St. Petersburg and the Louvre, the "Entombment" in the Borghese gallery, and the well known portrait of himself in the Uffizi at Florence. The production of works like these made Raphael's name famous over all Italy, and Pope Julius II. invited him to complete the frescoes of those halls of the Vatican which had been left unfinished by Nicholas V. and Pius II. In the middle of the year 1508 Raphael arrived at the papal court, and began that grand series of works which develop his third or Roman manner. His frescoes, cover-

ing the ceilings and walls of three chambers or *camere* and a large saloon, known collectively as the "Stanze of Raphael," were intended to glorify the power of the church, and to represent Rome as the centre of spiritual culture. The first saloon, called the *camera della segnatura*, he dedicated to representations of theology, poetry, philosophy, and jurisprudence, each of which is personified by an allegorical figure on the ceiling, while beneath, on the four sides of the apartment, are painted the principal subjects. "Theology," sometimes called the "Dispute of the Sacrament," consists of an assemblage of doctors and dignitaries of the church seated in council, above whom is represented, in the symmetrical and conventional manner of the early painters, a heavenly glory, with Christ throned on clouds and presiding over a host of patriarchs, saints, and angels. This, the first work executed by Raphael in Rome, is also the last of his large compositions which contains traces of his early religious, Peruginesque manner. The influence of the antique, which he here first felt in its fulness, the proximity of Michel Angelo, who was then painting his sublime frescoes in the Sistine chapel, and the importance and grandeur of the subjects upon which he was engaged, gave a new impulse to his genius, and he reached almost at a single step the limit of his style. His next work in point of date, "Poetry" or "Parnassus," representing an assembly of Greek, Roman, and Italian poets on Mount Parnassus, with Apollo and the Muses in the centre, marks perhaps the transition period; but in "Philosophy" or the "School of Athens," which followed, the Roman style is matured. The composition represents a grand hall or portico, in which are characteristically grouped the great philosophers and sages of antiquity. The remaining fresco in this *stanza*, "Jurisprudence," owing to the peculiar construction of the wall, is divided into three compositions, Gregory delivering the ecclesiastical law, and Justinian promulgating his code of civil law, above which are female personifications of prudence, fortitude, and temperance. These frescoes were finished in 1511, and appear to have been immediately succeeded by those in the *stanza* of Heliodorus, so called from the story of the expulsion of Heliodorus from the temple, as related in the second book of Maccabees, which is painted on one of its walls. In this composition the group of Heliodorus and the pursuing angels is especially noticeable for its supernatural power. The "Mass at Bolsena," "Attila terrified by a Celestial Vision," and "St. Peter delivered from Prison" occupy the remaining walls of this *stanza*; and on the ceiling are representations of the promises of God to the four patriarchs, Abraham, Isaac, Jacob, and Moses. Julius II. died during the progress of the work, but his successor, Leo X., directed its completion, as also that of the other works in the Vatican on which Raphael was engaged, besides intrusting him with new ones.

Before this time, however, commissions multiplied so greatly upon the painter's hands, that he was obliged to commit to the best of the numerous scholars who now resorted to him from all parts of Italy the execution of portions of the frescoes in the remaining *stanze* from his cartoons and designs. In this manner was painted the *stanza dell'incendio*, which takes its name from the principal subject illustrated, the "Fire in the Borgo," and in which are represented the prominent events in the lives of Popes Leo III. and IV. The frescoes in the *sala di Constantino*, the last of the series, were executed after his death under the direction of Giulio Romano, his most eminent pupil. They all suffered from neglect after the removal of the popes to the Quirinal palace, and were cleaned and in some instances restored by Carlo Maratti in the 18th century. While engaged on these works Raphael executed in fresco for Agostino Chigi, a banker of Rome, the four grand figures of the Sibyls in the Chigi chapel of Santa Maria della Pace, and the well known "Triumph of Galatea," besides many Madonnas and other easel pictures. His fortune kept pace with his celebrity, and he lived in princely magnificence, admired and beloved by all contemporary artists, excepting Michel Angelo, who ill endured the fame of his young rival. During the progress of the later works in the *stanze* Leo X. employed Raphael on the decoration of the *loggie*, or open galleries round three sides of the court of St. Damasus (the older portion of the Vatican), and the designs for the tapestries of the Sistine chapel. For the *loggie* he furnished a series of designs from the Old Testament, known as "Raphael's Bible," which were executed in 13 small cupolas on the gallery on the second story by Giulio Romano, Francesco Penni, Pellegrino da Modena, Perino del Vaga, and others of his pupils. A variety of beautiful arabesque ornaments and stuccoes in the same gallery were executed from his designs by Giovanni da Udine. The cartoons for tapestries, prepared probably between 1513 and 1516, represent the highest efforts of Raphael's genius in historical composition. They are from 14 to 18 ft. long by 12 high, and are colored in distemper. The subjects are "The Death of Ananias," "Elymas the Sorcerer struck with Blindness," "The Healing of the Lame Man at the Beautiful Gate of the Temple," "The Miraculous Draught of Fishes," "Paul and Barnabas at Lystra," "Paul preaching at Athens," and "The Charge to Peter." These cartoons, at the suggestion of Rubens, were purchased by Charles I. of England, and are now deposited in the South Kensington museum. The remaining cartoons of the series, representing "The Stoning of Stephen," "The Conversion of St. Paul," and "Paul in the Prison of Philippi," are lost. The original tapestries, for which the pope paid the manufacturers in Arras 50,000 gold ducats, after various mutations of fortune, are now in the

Vatican, but are so injured and faded that the general effect of the coloring is destroyed. Raphael also furnished the designs, but not the cartoons, for a second series of ten tapestries which are now in the Vatican. Amid these great undertakings he did not neglect the subjects which had first inspired his pencil, and the numerous Madonnas and holy families produced during his residence in Rome include some of the most characteristic and admirable of his works. Distinguished among them is the wonderful *Madonna di San Sisto* (painted between 1517 and 1520) in the Dresden gallery, representing the Virgin standing in a majestic attitude with the child in her arms. It is said to have been painted at once on the canvas, without any preliminary study, and has been engraved in a style not unworthy of the original by Friedrich Müller. Other celebrated Madonnas of this period are the *Aldobrandini Madonna*, in the possession of Lord Garvagh, that known as the *Bridgewater*, the *Vierge au diadème* in the Louvre, the lovely *Madonna della sedia* or *seggia* in the Pitti palace, the *Madonna di Foligno* in the Vatican, that called the "Pearl" at Madrid, and the *Madonna del pesce* in the Escorial, the two last mentioned being altarpieces with saints assembled around the Virgin. Of several of these duplicates exist, and all of them have been repeatedly engraved. Among his remaining easel pictures are the *St. Cecilia*, now in Bologna; the "Archangel Michael overcoming the Devil," in the Louvre; "Christ bearing the Cross," known as *Lo spasimo di Sicilia*, in Madrid; and his last, and by many considered his grandest work, the "Transfiguration," in the Vatican, painted in competition with Sebastian del Piombo's "Raising of Lazarus," of which Michel Angelo is said to have furnished the design. He executed upward of 80 portraits, the most famous being those of Julius II. and Leo X., the originals of both of which are in Florence, Cardinals Bibbiena, Bembo, de' Medici, and de' Rossi, Joanna of Aragon, and the "Fornarina," which was long supposed to represent one of his mistresses, but which Passavant considers to be the portrait of a celebrated improvisatrice named Beatrice Pio. The last named picture is in the Barberini palace in Rome. To this list of works must be added the fresco of "Cupid and Psyche" in the villa Farnesina, and numerous drawings in chalk, from which the engraver, Marc' Antonio Raimondi, executed several of his finest plates. Raphael also directed the construction of St. Peter's from his own plans subsequent to the death of Bramante in 1514, besides executing several other architectural works; and he made at least one statue in marble, besides designing others. He died of a fever caught in superintending some subterranean excavations, and was buried in the Pantheon, near the remains of Maria di Bibbiena, niece of the cardinal of that name, to whom he had been betrothed. Through some doubt as to the place of his

sepulture, his remains were exhumed in September, 1833, and on Oct. 18 reinterred with great ceremony. Of his private character Mrs. Jameson says: "There was a vulgar idea at one time prevalent that Raphael was a man of vicious and depraved habits, and even died a victim to his excesses; this slander has been silenced for ever by indisputable evidence to the contrary, and we may now reflect with pleasure that nothing rests on surer evidence than the admirable qualities of Raphael; that no earthly renown was ever so unsullied by reproach, so justified by merit, so confirmed by concurrent opinion, so established by time."—His life has been written by Quatremère de Quincy (Paris, 1824); by Passavant (3 vols., Leipsic, 1839-'58); by Baron von Wollzogen (1865; English translation by F. E. Bunnett, London, 1866); and more briefly by Mrs. Jameson in her "Memoirs of the early Italian Painters." See also Kugler's "Handbook of Italian Schools." The house in Urbino where Raphael was born was purchased in 1873, restored, and used as a museum.

RAPHALL, Morris Jacob. See supplement.

RAPIDAN, a river of Virginia, rising in the Blue Ridge mountains. It flows first S. and then E., forming the boundary between Greene and Orange counties on the right and Madison and Culpeper counties on the left, and empties into the Rappahannock about 10 m. above Fredericksburg. Its length is about 80 m.

RAPIDES, a W. parish of Louisiana, bounded N. E. by Little river, and intersected by the Red and Calcasieu rivers; area, about 2,000 sq. m.; pop. in 1870, 18,015, of whom 10,267 were colored, since which a portion has been taken to form Vernon parish. The surface is nearly level and the soil generally fertile. The chief productions in 1870 were 261,579 bushels of Indian corn, 54,276 of sweet potatoes, 9,133 bales of cotton, 8,868 lbs. of wool, 3,324 hhds. of sugar, and 212,860 galls. of molasses. There were 2,225 horses, 1,976 mules and asses, 3,748 milch cows, 1,218 working oxen, 9,259 other cattle, 3,848 sheep, and 14,724 swine; 18 establishments for the manufacture of sugar, and 1 saw mill. Capital, Alexandria.

RAPIN, Paul de, sieur de Thoyras, a French historian, born in Castres, March 25, 1661, died in Wesel, May 16, 1725. He became an advocate, but turned his attention to arms and literature. Being a Protestant, he went to England on the revocation of the edict of Nantes (1685), and afterward to Holland, where he joined a company of French cadets, and followed the prince of Orange (William III.) to England. He was at the battle of the Boyne, and was wounded in the siege of Limerick. He afterward became tutor of the young duke of Portland, and in 1707 settled in Wesel on the Rhine. His most important work is his *Histoire d'Angleterre* (9 vols. 4to, the Hague, 1724), in which the narration of events is carried down to the death of Charles I. It was translated and continued by N. Tindal, and has

been often printed (2 vols. fol., 1732-'3; 5 vols. fol., 1743-'7; 21 vols. 8vo, 1757-'9).

RAPOPORT. See **RAPPAPORT**.

RAPP, Georg, founder of the sect of Harmonists, born in Württemberg in 1770, died at Economy, Pa., Aug. 7, 1847. Believing that he had a divine call, and was charged with the restoration of the Christian religion to its original purity, he organized a community on the model of the primitive church, with goods in common. A difficulty with the government in regard to worship impelled Rapp to transplant his community in 1803 from Württemberg to the United States. They settled first on Connequenessing creek, in Butler co., Pa., where they founded the village of Harmony, and employed themselves in agriculture and manufactures. They acquired considerable wealth, and in 1815 removed to the territory of Indiana, where they had purchased a tract of 27,000 acres on the Wabash. The settlement of New Harmony here was even more prosperous than their former establishment, but in 1824 they sold the property to Robert Owen, and emigrated to Beaver co., Pa., where the town of Economy was laid out on the right bank of the Ohio, 17 m. N. W. of Pittsburgh. It is an agricultural and manufacturing community. Members of both sexes are admitted, but they do not marry; they profess Protestantism, observe strict morality, and pay much attention to education. There was a secession of about 200 members in 1832. The village of Harmony (pop. in 1870, 225) was in 1851 set off from the township of Economy (pop. in 1870, 1,324).

RAPP, Jean, a French general, born in Colmar in April, 1772, died in Paris, Nov. 8, 1821. He entered the French army as a private in 1788, distinguished himself during the wars of the revolution, and was an aide-de-camp of Desaix in Italy and Egypt. After the battle of Marengo Napoleon attached him to his staff, and when he became emperor Rapp was promoted to brigadier general. At Austerlitz he decided the victory by precipitating his force upon the Russian imperial guard, and was made general of division. He distinguished himself in the succeeding campaigns, especially at Golymin (1806), where he was wounded for the ninth time. To enable him to recruit his health he was intrusted with the government of Thorn, and subsequently with that of Dantzic. He was in the campaign of 1812 against Russia, receiving at the Moskva his 23d wound; and after the disastrous result of that invasion he withdrew to Dantzic, where he was blockaded by the Prussians and Russians. He held out 12 months, but finally surrendered, and was carried to Russia as prisoner of war. Returning to France on the restoration, he was sent to oppose the return of Napoleon, but went over to his old leader, who appointed him commander-in-chief of the army of the Rhine. But being pressed by an Austrian army superior to his, he retired to Strasburg, and after the second restoration

went to Switzerland. In 1818 he returned to France, was reinstated in the army, and in 1819 was made a peer. He left a volume of "Memoirs," published in 1823.

RAPPAHANNOCK, a river in the E. part of Virginia, formed by the confluence of the North fork and other small streams, which rise in the Blue Ridge and unite on the N. E. border of Culpeper co. At the S. E. extremity of that county it receives the waters of the Rapidan, its largest tributary; thence flowing in a devious course, it reaches tide water at Fredericksburg, where by a fall it supplies valuable power; thence it becomes navigable, and enters Chesapeake bay by an estuary about 60 m. long. The whole length in a straight line from its sources to Chesapeake bay is about 140 m., but with its numerous and intricate windings its real length must be nearly twice as much. Its general course is S. E.

RAPPAHANNOCK, a N. E. county of Virginia, bordered N. E. by the North fork of the Rappahannock, and drained by others of its head waters; area, about 250 sq. m.; pop. in 1870, 8,261, of whom 3,066 were colored. It is bordered N. W. by the Blue Ridge, and has a generally fertile soil. The chief productions in 1870 were 103,112 bushels of wheat, 10,755 of rye, 304,040 of Indian corn, 44,297 of oats, 2,058 tons of hay, 23,918 lbs. of tobacco, 15,036 of wool, 87,426 of butter, and 3,319 gallons of sorghum molasses. There were 2,087 horses, 1,904 milch cows, 5,192 other cattle, 3,655 sheep, and 5,615 swine. Capital, Washington.

RAPPAPORT, or **Rapoport**, Solomon Judah, a Jewish antiquary, born in Lemberg in June, 1790, died in Prague, Oct. 16, 1867. He published critico-biographical and other essays in the Hebrew periodicals *Bikkurei ha'ittim* (Vienna, 1820-'31) and *Kerem 'hemed* (Vienna and Prague, 1833-'45), which raised him to the highest rank among the Hebrew scholars of the age. The most important of his numerous writings, including the posthumous *Na'halath Yehudah* (Cracow, 1869), is the first volume of a Talmudo-rabbinical encyclopædia entitled *Erekh millin* (Prague, 1852). He was elected rabbi of Tarnopol in 1837, and of Prague in 1840, and held the latter position till his death.

RARATONGA, or **Rarotonga**. See **Cook's ISLANDS**.

RARITAN, a river of New Jersey, formed by the confluence in Somerset co. of two branches, both having their sources in the mountains of Morris co.; the North branch flows mainly due S., and the South branch makes a curve S. W. through Hunterdon co., and then forms a circuit to the north. From the junction the course of the Raritan is nearly E. It passes by New Brunswick, whence it is navigable to Raritan bay, which it enters at Perth Amboy. The main stream is about 33 m. long.

RASCIA, in the middle ages, the name of southern Servia, derived from Rasa (now Novi-Bazar), on the Rashka, and subsequently ex-

tended to the whole of the Servian kingdom. The name Rascians, variously modified, is still used in Hungary, Roumania, and other countries, to designate various Serb populations living outside of Servia.

RASHI. See SOLOMON BEN ISAAC.

RASK, Rasmus Christian, a Danish philologist, born at Brendekilde, on the island of Fünen, Nov. 22, 1787, died in Copenhagen, Nov. 14, 1832. He graduated at the university of Copenhagen, was appointed an assistant in the university library in 1808, and in 1811 published in Danish his "Introduction to the Study of the Icelandic or Old Norse Language." In 1812 he went to Sweden, and in 1813 to Iceland, where he remained three years studying its history and literature. In 1817 he was in Stockholm, and in 1818 and 1819 in Finland and St. Petersburg, occupied with the study of Finnish, Russian, Armenian, Persian, and Arabic. From St. Petersburg he went to Persia, thence to India and Ceylon, and returned to Copenhagen in 1823. He was appointed professor of literary history in the university in 1825, of oriental languages in 1828, and first librarian in 1829. According to Bunsen, Rask anticipated some of the greatest discoveries of Grimm, Bopp, and Burnouf. He published Icelandic, Anglo-Saxon, Spanish, Frisian, Danish, and Lappish grammars, and works on the ancient Egyptian chronology, on the oldest Hebrew chronology, and on the Thracian and Zend languages. After his death his contributions to various journals were collected, with a life by Petersen (3 vols., Copenhagen, 1834-'8).

RASKOLNIKS, or **Roskolniks**, the principal class of Russian dissidents. See RUSSIA.

RASPAIL, François Vincent, a French naturalist and revolutionist, born in Carpentras, Jan. 29, 1794, died June 8, 1878. He studied at Avignon, settled in Paris in 1815 as a scientific writer, and was wounded in the revolution of 1830. He was subsequently a journalist, spending many years in prison on account of his revolutionary writings. He led the populace in 1848 to proclaim the republic, and was afterward again imprisoned till 1854, although elected in 1849 to the national assembly. In the interval he had also been imprisoned for illegal practice of medicine. He had sold camphor in the form of cigarettes as the best remedy against internal and external parasites, and written much on the subject. In 1869 he was elected to the legislative body, and joined Rochefort in editing the *Marseillaise*. In 1870-'71 he was identified with the commune movement. His principal works are: *Nouveau système de chimie organique* (new ed., 3 vols., 1838); *Nouveau système de physiologie végétale*, &c. (2 vols., 1837); *Histoire naturelle des ammonites et des térébratules* (3 vols., 1842; new ed., 1866); *Histoire naturelle de la santé et de la maladie* (3 vols., 1839-'43; 3d ed., enlarged, 1857); *Manuel de la santé* (annual, 1846-'65); and *Nouvelles études scientifiques et philologiques* (1865).

RASPBERRY, the name (of very doubtful derivation) of fruit-bearing shrubs of the genus *rubus*, of the order *rosaceæ* or rose family. The genus consists of shrubs or half-shrubby (and a few herbaceous) perennial plants, with mostly compound leaves; the lobes of the bractless calyx persistent; petals five; stamens and pistils numerous; the ovaries containing two ovules, and in fruit becoming one-seeded pulpy drupes, which cohere in a head or cluster above the open calyx. It is one of those genera in which the species are so variable that their number has been unduly increased by local botanists; over 500 have been described, but there are probably not more than 100 good species. The genus *rubus* includes both the raspberries and the blackberries; in the former the drupes cohere, and when ripe fall away from the dry receptacle, or in some species there are only a few grains which fall separately, while in the latter the drupes remain attached to the receptacle. Our native raspberries are divided into three sections: 1. With simple leaves, large flowers, plant without prickles, and the fruit very flat and broad. To this section belongs what is called in this country the rose-flowering, and in England the Virginia raspberry, *R. odoratus*; it is about 5 ft. high, with ample three- to five-lobed leaves, which as well as the young shoots are viscid with glandular bristly hairs; the flowers, of a rich rose-purple color, are about 2 in. across; the fruit, which is variable, is sometimes an inch broad, very flat, reddish, with a rather pleasant flavor, though dry. This is found in rocky places from Canada to the mountains of Georgia, and is sometimes seen in cultivation, though not so often as it deserves; its large flowers, varying in depth of color, appear much like single roses, and it blooms at midsummer, when but few shrubs are in flower. The white-flowering raspberry, *R. Nutkanus*, was first discovered at Nootka on the N. W. coast, but has later been found to extend as far east as upper Michigan; among other differences from the foregoing, it is not bristly and has white flowers. The Rocky mountain bramble, *R. deliciosus*, is hairy, and has smaller leaves and larger flowers than either of the preceding; it has recently been introduced into gardens, and will be popular on account of its abundant flowers, which are pure white, and have a peculiarly delicate texture; the specific name was given it by Torrey, from the accounts of the fruit given by the discoverer Dr. James; but it proves to be very indifferent. Belonging to the same section is the cloudberry, *R. chamæmorus*, a low, creeping, nearly herbaceous, dioecious, subalpine species, with white flowers, and a few amber-colored, very large grains; it is also a European species, and is found throughout arctic America, on the White mountains above the tree line, and at Mount Desert and other points on the eastern coast, where its fruit is called the baked-apple berry. 2. The second section comprises low, mostly

herbaceous, and unimportant species. 3. Species with biennial, woody, and prickly stems, and three to five foliolate compound leaves. The common wild red raspberry is found from Newfoundland to Oregon, and as far south as the middle states. The upright stems are bristly and prickly; the leaves, with three to five oblong-ovate, serrate leaflets, are covered on the under side with a white down; the petals as long as the sepals, the fruit light red. This species is abundant northward, especially on recently cleared lands, where it produces fruit in great profusion all summer. The garden raspberry of Europe, *R. Idæus*, is so very near this that it is difficult to find good botanical characters to separate them; this species has been improved by raising seedlings under cultivation; varieties derived from it are the Allen, Kirtland, scarlet, and others. The plant propagates itself abundantly by underground stems, which run beneath the surface for several feet and appear above ground as suckers; these stems grow to their full height, 5 or 6 ft., in one season, bear their fruit the next summer, and then die; the European raspberry has a similar manner of growth, and the cultivation of the varieties of this species is the same as given below for that.—The black raspberry, *R. occidentalis*, also called blackcaps and thimbleberry, is more widely distributed than the red, extending as far south as Georgia; it has prickly stems with a glaucous bloom; leaflets mostly three and white underneath; the petals shorter than the sepals; the fruit black, with whitish varieties, ripe in July, drier than the red, and with a distinct and peculiar flavor. In manner of growth this is very different from the red raspberry; it makes no distant suckers, but new shoots spring up from the base of the old plant, and late in summer the branches, which grow very long, become recurved, until finally their tips reach the ground, where they take root and form new plants; in cultivation this process is aided by covering the ends of the branches with a little earth. Within the past 20 years much attention has been given to cultivating varieties of this species, and they are now very popular. Among the cultivated sorts are Doolittle's, Seneca, Davidson's thornless, Miami or Mammoth cluster, and the whitecap. In cultivating for fruit, the stems are stopped by pinching when about 3 ft high, and the side branches are also stopped, forming a compact branched bush, which will bear a great quantity of fruit; but if it is desired to multiply plants, the branches are allowed to grow, bend over, and reach the ground as described above.—There is a set of native raspberries which appear to have escaped the attention of botanists, but are well known to cultivators as the purple-cane family; the plants have the habit of growth of the black, but the fruit, though dark-colored, resembles in form and flavor the red raspberry; it has been suggested that these have originated by hybridizing the black and

red species. They are not so high-flavored as the red kinds, but as they bear profusely and do not sucker, they are better adapted to small gardens; the varieties are purple cane, Catawissa, Ellisdale, and a few others.—The garden raspberry, *R. Idæus*, so named from Mount Ida, is found all over Europe and in Russian Asia; it only differs from our native red species in being a taller plant, with thicker leaves and firmer, larger, and better fruit. This species was cultivated by the Romans in the 4th century, and the oldest English writers on rural matters mention it, some giving both a red and a white kind. There are over 50 varieties in the fruit lists, very few of which are generally cultivated; among the most popular kinds are those which have been raised in this country from seed. The berry with which the New York market is mainly supplied is the Hudson River Antwerp, a red variety of unknown (though supposed English) origin; immense quantities are brought from various lo-

European Raspberry (*Rubus Idæus*).

calities along the Hudson, and it has not yet been superseded by any other; among the other popular varieties of this class are Belle de Fontenay (with many synonymes), Clarke, Downing, Fastolf, Franconia, Hornet, Brinckle's orange, and Philadelphia. The last named is by some regarded as a native; it is a great bearer even on poor soils, and, though not of first quality, is one of the most profitable. These varieties are propagated by suckers, which most of them produce in abundance; after the sucker has grown a year it is separated from the parent plant, and, its stem being cut back to a few inches, is taken up for planting. A plantation is made in autumn or very early in the spring, setting the plants, according to the vigor of the variety, 4 to 6 ft. apart each way; two or three shoots are allowed to grow from the plant the first season, and not more than six thereafter; they are supported by tying to stakes, or to wires stretched along the rows; the shoots bear fruit the second

year, and at the same time new shoots are produced, which will fruit the following year; as soon as the fruit is gathered the old canes are cut out, and all surplus shoots are removed. All the foreign varieties in the northern states (and they do not succeed in the southern) need to be covered in winter.

RASSAM, Hormuzd. See supplement.

RASSE. See CIVET.

RASTADT, a fortified town of Baden, on the Murg, 14 m. S. W. of Carlsruhe; pop. in 1871, 11,559. It has a fine palace, a Protestant and several Catholic churches, a Catholic normal school, a lyceum, and a museum. A congress met here in November, 1713, and a treaty of peace was signed March 6, 1714, ending the Spanish war of succession. The treaty of peace of Campo Formio and the secret Rastadt convention of Dec. 1, 1797, gave to France all German fortresses on the Rhine. At the second congress of Rastadt for peace between France and Germany, which opened Dec. 9, 1797, the extravagant demands of the French were granted; but war being renewed, the congress broke up in April, 1799, and the French ambassadors, on leaving, were murdered near the town by Austrian hussars (April 28). By the treaty of Vienna of 1815 Rastadt became a fortress of the Germanic confederation. The Baden revolution of 1849 began here May 11, with a mutiny of the Badenese troops, which was followed by a rising in Carlsruhe. A few days later the Austrian garrison abandoned the fortress, which was occupied in June by the insurgent troops under Mieroslawski, a provisional government having replaced that of the grand duke. The rising extended to the Rhenish Palatinate, but was suppressed by Prussian intervention under the command of the crown prince (the present emperor William). Rastadt was blockaded at the end of June, and bombarded on July 6 and 7, and surrendered on July 23. It was occupied by the Prussians from that time till 1866.

RAT, a well known rodent, the type of the subfamily *murinae*. In the murine tribe of this

body 8 to 10 in. long, and the tail 6 to 8 in., scantily covered with hair and with about 200 rings; the color above is grayish brown mixed with rusty, grayer on the sides, and ashy white below; the upper surface of the feet dirty white. This species, originally from India and Persia, entered Europe through Russia, appearing in the central countries about the middle of the 18th century; it was brought to America about 1775, and has since greatly increased in numbers, driving out here as in Europe the black rat which had been previously introduced; it is now generally distributed over the world, having been transported in ships, and most abundantly near the seacoasts. Its haunts are cellars, sewers, canal docks, and similar dirty places, wherever it can make a burrow or find abundant food; it is a great household pest, and so prolific that its devastations are sometimes very great; it breeds from three to five

Black Rat (*Mus rattus*).

times a year, having 12 to 15 at a birth, the males always being the most numerous. Not only the black rat, but other species indigenous to the old world, are driven off or destroyed by it; the dead and even living persons are attacked by it when hard pressed; it is not only pursued by man, dogs, and cats, but the stronger will kill and devour the weaker of its own species. The black rat (*M. rattus*, Linn.) is 7 or 8 in. long, with a tail of $8\frac{1}{2}$ in.; the color is very dark, often nearly black, with numerous long hairs projecting from the short and soft fur, plumbeous beneath, and the feet brown; it has a slighter form than the brown rat, with the upper jaw more projecting, the ears larger, and the tail much longer in proportion. It is not very strong, but exceedingly active; being rather timid, it is exterminated by the larger and fiercer brown rat; the habits of the two species are much the same, but the black rat is less a burrowing animal, and prefers the upper parts of houses to cellars and low dirty places. It used to be the common house rat in Europe and warm countries, until driven off by its congener; it appears to have been brought to the new world about the middle of the 16th century; it came originally from central

Norway Rat (*Mus decumanus*).

subfamily, confined originally to the old world, belong the common house rats. The brown or Norway rat (*mus decumanus*, Pall.) has a

Asia; like the preceding species, it is omnivorous. The roof or white-bellied rat (*M. tectorum*, Savi) is about $6\frac{1}{2}$ in. long, and the tail about 8 in. with 240 rings; it is colored above like the brown rat, the lower parts and upper surface of feet yellowish white; the head is rather blunt, the eyes large, whiskers long and black, ears very large, and the thumb rudimentary. It came originally from Egypt and Nubia, thence passed to Italy and Spain, and from the last to America in the 15th century; it is common in Mexico and Brazil, and in the southern states, but is rarely found above North Carolina; it is fond of inhabiting the thatched roofs of houses, whence its name; it is the same as the *M. Alexandrinus* (Geoffr.) and *M. Americanus* (Seba). Some of the East Indian rats are far larger than any of these; the giant rat of Bengal and the Coromandel coast (*M. giganteus*, Raffles) has a body 13 in. long and a tail as much more; this is very destructive in gardens and granaries, devouring chickens and ducks, undermining houses, and piercing the mud walls; it is the largest of the subfamily, a male weighing as much as 3 lbs.; it is often eaten by the lower caste Hindoos.—All these rats are very fond of fighting, and with their omnivorous habits are decidedly murine cannibals, eating not only their conquered brethren but their young. Though living in the filthiest places and in the foulest air, they always have a sleek coat, and take the greatest pains to clean themselves, licking the paws in the manner of a cat; during mastication the jaws move very rapidly; they drink by lapping; when asleep the body is coiled in a ball, with the nose between the hind legs, and the tail curled around the outside, leaving only the ears out ready to catch the least sound of danger; as food fails they migrate in companies from one place to another. There are more muscles in a rat's tail than in the human hand; this most useful appendage, with its chain of movable bones and numerous muscles, is covered with minute scales and short stiff hairs, rendering it prehensile, and capable of being employed as a hand, balancer, or projecting spring. The teeth are long and sharp, but there is nothing specially dangerous in wounds made by them; their strength enables them to gnaw ivory, as dealers in this article well know; in fact, even in Africa, elephants' tusks are found gnawed by rats, squirrels, porcupines, and perhaps other rodents, as long as any gelatine is contained in them. They are very subject to tumors of the skin, which often end fatally; they also perish soon without water. These animals have their uses, especially for devouring refuse matters which would otherwise engender disease, as in tropical climates or in large cities, in the sewers of which they live in legions; their skins are employed for various purposes, as in the manufacture of the thumbs of gloves, but are too delicate for any article requiring much strength. The Chinese and other Asiatic nations, and

many African tribes, eat the flesh of rats; and arctic travellers have often found them a welcome addition to their bill of fare.—In the sigmodont tribe of the *murinae*, belonging entirely to the new world, besides the genera

Florida Rat (*Neotoma floridana*).

noticed under Mouse, may be mentioned *neotoma* (Say and Ord); in this the fur is soft and full, the form rat-like, the tail long and more or less hairy; ears very large and nearly naked; molars rooted; heels hairy. It is peculiar to North America, and found in the United States except New England; some of the species are much larger than house rats, and are rather handsome. The Florida or wood rat (*N. floridana*, Say and Ord) is about 8 in. and the tail 6 in. long, the short stiff hair of the latter not concealing the scaly rings; the color above is plumbeous mixed with dark and yellowish brown, lighter on the sides, beneath and the feet white; tail dusky above, white below; the head is sharp. It is abundant in the southern Atlantic and gulf states, and is found occasionally in the west; the habits vary much in different localities, living in some places in the woods, in others under stones or in the ruins of buildings; in swampy districts it heaps up mounds, 2 or 3 ft. high, of grasses, leaves, and sticks cemented with mud; sometimes the nest is in the fork or the hollow of a tree. It is crepuscular, very active and an excellent climber; the food consists of corn, nuts, cacti, crustaceans, mollusks, and various roots and fruits; the disposition is mild and docile; from three to six young are produced twice a year. Larger species are found west of the Rocky mountains, very destructive to the furs, blankets, and stores of the trappers; for an account of these see vol. viii. of the "Reports of the Pacific Railroad Expedition." In the bone caves of Pennsylvania have been found the remains of a species whose body must have been at least 12 in. long.—In the genus *sigmodon* (Say and Ord) the general appearance is that of a

large field mouse; the body is stout, the hair long, the muzzle blunt and hairy except on the septum; the upper lip slightly notched; thumb rudimentary; soles naked, with six granular tubercles; incisors stout, the upper much rounded; ears and tail moderate; molars rooted, with a plane surface, the last two lower with the enamel in the form of an S, whence the name. The genus is confined to the southern parts of the United States. The best known species is the cotton rat (*S. hispidus*, Say and Ord), about 5 in. long with a tail of 4 in.; the color above is reddish brown, brightest on the sides, lined with dark brown, and under parts grayish white; the hair is long and coarse, and the claws very strong. It is more abundant in the southern states than the meadow mice in the north, living in hedges, ditches, and deserted fields, and consequently doing but little damage to the planter. It is gregarious, feeding on seeds of grasses and

Cotton Rat (*Sigmodon hispidus*).

leguminous plants, and also on flesh; it picks up wounded birds and small mammals, crawfish, and crabs; it is very fierce and pugnacious, the stronger killing and devouring the weaker, and the males often eating the young; it is also very fond of sucking eggs. Nocturnal in habit, it is seen by day in retired places; it digs very extensive galleries not far from the surface, a family in each hole; it breeds several times a year, having four to eight in a litter; it swims and dives well. It received its name from its lining the nest with cotton. It is preyed upon by foxes, wild cats, hawks, and owls. It is not found north of Virginia.

RATAZZI. See RATAZZI.

RATIBOR, a town of Prussian Silesia, on the Oder, which is here navigable, 90 m. S. E. of Breslau; pop. in 1871, 15,323, chiefly Roman Catholics. It has one Protestant and several Catholic churches, and a Protestant gymnasium attended by about 500 students. The principal trade is in grain and timber; tobacco is manufactured. It was formerly the capital of a principality, which belonged to the house

of Hapsburg from 1532 to 1742, when it was taken by the Prussians. From 1822 to 1834 it belonged with its castle (burned in 1858) and domains to the landgrave Victor Amadeus of Hesse-Rothenburg, and it is now held as a dukedom by Prince Victor of Hohenlohe-Waldenburg-Schillingsfürst.

RATISBON (Ger. *Regensburg*; anc. *Reginum*; mediæval Lat. *Ratisbona*), a city of Bavaria, capital of the united district of the Upper Palatinate and Ratisbon, on the right bank of the Danube, opposite its junction with the Regen, 65 m. N. N. E. of Munich; pop. in 1871, 29,224, including about 6,000 Protestants, the rest being chiefly Catholics. It is a city of great antiquity, having crooked streets and tall, quaint houses with gable roofs, and intervening lofty towers. The restoration of the cathedral, founded about 1275, was completed in 1875; it has a richly sculptured portal, and is one of the grandest Gothic structures in Germany. The abbey of Emmeran, dating from 652, and improved by Charlemagne, consists of a vast pile of buildings, including the half ruined church with the shrine of St. Emmeran, the patron saint of the city; the cloisters have been embellished and enlarged by their present owner, Prince Thurn and Taxis. The Bischofshof, once the residence of German emperors, and where Maximilian II. died, is now a brewery. The city has a town hall with interesting historical associations, an observatory, a lyceum, a gymnasium, an ecclesiastical seminary, an institution for the deaf and dumb, a public library, a well endowed hospital, and a fine promenade (*Fürstengarten*) at the rear of the Thurn and Taxis palace, with a monument of Kepler, who is buried in the Protestant cemetery. The most celebrated building in the vicinity of Ratisbon is the Walhalla, the Bavarian pantheon, at Donaustauf; it consists of a Doric marble temple after the model of the Parthenon of Athens, begun in 1816 by Klenze for the crown prince, afterward King Louis I., and opened in 1841. The Danube is spanned in Ratisbon by a stone bridge nearly 1,500 ft. long. The shipping trade chiefly consists of timber, grain, and salt, of which Ratisbon is the principal depot. Gold, silver, steel, tin, and other wares are made, and there are many breweries and distilleries.—Under the Romans Ratisbon was an important frontier fortress of Vindelicia. Subsequently it became a commercial centre, and in the 6th century the capital of Bavarian dukes. The important bishopric of Ratisbon was established in the 8th century. In the 12th century it was made a free imperial city. In 1633-'4 it was successively taken by Maximilian of Bavaria, Bernard of Weimar, and the imperial troops. From 1663 to 1806 it was almost continually the seat of the German imperial diet. Under Charles Dalberg, elector of Mentz, the city and the see of Ratisbon formed together a principality from 1803 to 1810, when both were incorporated with the kingdom of Bavaria.

RATTAN. See PALM, vol. xiii., p. 18.

RATTAZZI. I. Urbano, an Italian statesman, born in Alessandria, June 29, 1808, died in Frosinone, June 5, 1873. He became an advocate, and in 1848 was elected a member of the Sardinian parliament. For a short time in July he was minister of instruction. A steady opponent of peace with Austria, he joined in December Gioberti's cabinet as minister of justice, and succeeded him in February, 1849, as its virtual head, with the portfolio of the interior. He retired on the abdication of Charles Albert after the disastrous battle of Novara at the end of March. His continued parliamentary opposition to Austrian domination in Italy resulted in the election of a new parliament, in which he formed a middle party (*il connubio*) acting in concert with Cavour and the liberal conservatives. In Cavour's cabinet Rattazzi became minister of justice in October, 1853, and at the end of May, 1855, minister of the interior. Early in 1858 he withdrew on account of a considerable accession to the ranks of the clerical party in the chamber, after having carried through the partial suppression of monasteries and other religious bodies. In January, 1859, he was elected president of the chamber, and after the peace of Villafranca replaced Cavour as head of the cabinet, but again gave way to the latter on Jan. 20, 1860. His unpopularity was increased by his refraining from voting on the question of the annexation of Nice and Savoy to France, and it was only in February, 1861, that Cavour could prevail upon the chamber to accept him again as president. After the death of Cavour he opposed Ricasoli, and took his place as premier in March, 1862. Against his former policy, he was obliged to combat the revolutionists at Sarnico, Aspromonte, and other places, without gaining any advantage in the Roman question, and had to resign in December. In 1863 he fought a duel with his political adversary Minghetti. From April to October, 1867, he was for the last time prime minister. By the Garibaldians, who were soon afterward defeated at Mentana owing to the measures which he had taken, he was accused of subserviency to Napoleon III., while the clerical party charged him with encouraging the Garibaldians; but in parliament he vindicated his course (Dec. 18, 19) by pleading the international obligations which the government was bound to observe. II. Marie Studolmine, a French writer, wife of the preceding, born in London about 1830. Her mother was the princess Lætitia, a daughter of Lucien Bonaparte, and her father was Sir Thomas Wyse, English minister at Athens. The separation of her parents left her without resources, and Louis Philippe placed her in a royal school at St. Denis. In 1850 she married M. Frédéric Solms, a rich Alsatian, from whom she separated in 1852. Louis Napoleon objected to her residing in Paris on account of her political intrigues, and she afterward lived in Savoy and at Nice under the name of the prin-

cess Marie de Solms, engaged in literary labor, and intimately associating and corresponding with many eminent men. In 1860 she returned to Paris, and subsequently went to Florence, where in 1862 she married Rattazzi. Lately she has resided in Paris. The best known of her many novels are *Les mariages de la créole* (1866) and *Si j'étais reine* (1868). She has also published poems and dramas (often acting in the latter), and edited several journals.

RATTLESNAKE, an American venomous serpent, the type of the family *crotalidæ*, which includes several species, all characterized by a deep pit lined with small plates on each side, beneath and usually a little behind the nostrils. In the genus *crotalus* (Linn.) the head is very

Head of Rattlesnake, showing Poison Fangs.

large, flattened above and triangular, scaly on the crown, with small shields on its sides and the nose; eyes large and brilliant; teeth very small, but the true maxillaries, which are small and attached to the cranium by a small pedicel and by ligamentary union, have a single pair of long curved fangs, laid flat during inaction, but erected when the mouth is opened; these fangs are channelled for the conveyance of the poison secreted by a gland on each side of the head, beneath and behind the eyes; behind the fangs are the rudiments of others, which are developed as occasion requires; there are also two rows of small fixed teeth on the palate; the belly is covered with broad shields; the trunk and tail are scaly above, and nearly all the subcaudal scutes simple. The last three to eight caudal vertebræ coalesce to form a

Rattle and Section of Rattle.

single terminal conical and compressed bone, covered by muscle and a thick spongy skin which secretes the pieces of the rattle, an appendage of loosely articulated horny segments, whose rattling noise has given the popular name to this genus; the rattle may consist of 20 or 30 pieces, the smallest at the end; they

are securely strung together, each consisting of three annular portions, the basal ring of one grasping the second of the preceding, and this again enclosing the third of the joint next but one preceding; the first only has a vital connection with the skin; this apparatus is made to vibrate by the muscles of the tail, with a sound like that of peas in a dry pod. The sound of the rattle closely resembles that made by the 17-year locust (*cicada*) and grasshoppers. It is popularly but erroneously believed that the age of the snake can be estimated by the number of the rattles; though these may increase with age, their fragility is such that many may be lost from accident; and moreover, more than one may be added annually, according to the vigor, food, state of captivity, &c., of the animal; 20 are not unfrequently seen in large specimens, but it would be incorrect to conclude from these that the snake was neither more nor less than 20 years old. As the bite of these reptiles is speedily fatal to small animals, it has been generally believed that the use of the rattles is to warn animals and man of its vicinity; but, as other equally and even more dangerous species have no such apparatus, it is more likely that its use is to startle the squirrels, birds, and other creatures upon which it preys from their retreats, or for some other purpose for its own welfare rather than the safety of man. It may serve for its own protection by alarming its enemies and drawing attention to its menacing attitude; yet were this the case we should expect the young to be best provided with this apparatus, whereas it increases in size with age; it has been suggested that it is to call the sexes together. (See vol. vi. of "American Naturalist," 1872.) Rattlesnakes rarely attack man unless provoked, and are sluggish in their movements, unable to spring except from a coil, and are disabled by slight blows. They are ovo-viviparous, the eggs being retained until hatched, and the young expelled alive; in winter they retire to holes in the ground, and there remain torpid, several interlaced with each other; they are unable to climb trees, and do not follow a retreating animal which has escaped their spring. They are said to be fond of music, like many other serpents. Some Indians are afraid to kill them, lest the spirit of the slaughtered animal should excite its living relatives to avenge its death. They are capable of attaining to a considerable age, and are tenacious of life under circumstances speedily fatal to most other animals.—The most common is the banded rattlesnake (*C. [urotophus] durissus*, Linn.), 4 to 5 ft. long, ash-colored above with irregular transverse dusky bars, confluent near the tail; vertebral line yellowish, the sides tinged with the same; the body is thick and robust and the tail short and thick; in a specimen about 4 ft. long the head was 2 in., the body 40, the tail $3\frac{1}{2}$, and nine rattles 2 in., the greatest circumference being 6 in.; there were 177 broad abdominal plates, and 25 under the tail; in the

young the tail is black. It is generally distributed throughout the United States, from lat. 45° to the gulf of Mexico, and from the Atlantic to the Mississippi and Red rivers; it preys

Rattlesnake (*Crotalus durissus*).

principally on rabbits, squirrels, rats, and small birds, quietly waiting for them to come within its reach, its bite proving fatal to animals of this size in less than a minute when the snake is in full vigor. It is now rarely met with in the northern states, except in uncultivated and rocky places, remote from dwellings; it is more common in the western states, where its fat is highly prized as an antidote to its bite, and also for rheumatic and neuralgic pains; cattle are often bitten by it, and it is the custom there to cast them and bury the wounded part in the mud, recovery taking place rapidly; this shows the comparatively little danger for a large animal, as there can be nothing curative in the application made. The diamond or water rattlesnake (*C. adamanteus*, Beauv.) is dark brown or dusky above, with a series of large rhomboidal spots continuous from head to tail; abdomen dirty yellowish white; the mouth is large, the neck small and contracted, and the body long and thick; it is the largest of the genus, and may attain a length of 8 ft.; in one about 6 ft. long the head was $2\frac{1}{2}$ in., the body 60, the tail $2\frac{1}{2}$, and the rattles 3 in.; abdominal plates 172, and 25 subcaudal. It frequents damp and dark places, always near water, though not living in it; it is one of the most hideous and sullenly ferocious serpents of the family; its range is very limited, from North Carolina to East Florida, on the seacoast. The *C. horridus* (Linn.) is a native of the warm parts of South America; it

attains a length of 5 or 6 ft. and the thickness of a man's wrist; the color is yellowish brown varied with darker, on the lower parts lighter; there are wide lozenge-shaped spots along the back edged with white, with light stripes and other smaller and less distinct spots on the sides; brownish black bands between the eyes, and from the top of the head along the neck. It is found only in dry, rocky, elevated regions, covered with thorns and bushes; the negroes esteem its flesh a delicacy; it often bites and destroys cattle coming near its retreat, the poison being more virulent in tropical climates. —The genus *crotalophorus* (Gray) seems to connect *crotalus* with *trigonocephalus* (copper-head), having the rattles of the former and the plates on the head of the latter. The small or ground rattlesnake (*C. miliarius*, Gray) is dark gray above, with a brownish red vertebral line interrupted by a row of subquadrate black spots margined with yellow; a double series of black spots on each side, the upper larger but less distinct, and a white streak backward from the eyes. It is generally from 16 to 18 in. long, and is common in the United States as far N. as lat. 35°, in dry places among leaves, preying on field mice and small birds; its bite is fatal to small animals, but not to man. The prairie rattlesnake (*C. tergeminus*, Say) is a little over 2 ft. long; it is cinereous above, with a triple series of dark brown spots, and a double series of dusky spots below; it is fond of hiding in the holes of the prairie dog (*cynomys*), on the young of which it chiefly feeds; it occurs in the country near the Rocky mountains and the sources of the Missouri. Other species are described by Dr. Holbrook, and by Baird and Girard. —The poison gland is compressed by the temporal muscle during the act of striking; there is a very extensive communication of the glandular tissue with the vascular system, the blood vessels surrounding the secreting tubes in a capsular manner. Microscopically the poison appears as a limpid hyaline serum, with crystals of ammonio-magnesian phosphate, according to Dr. W. I. Burnett. According to Dr. Mitchell it is yellow, acid, glutinous, of a specific gravity of 1.04; devoid of taste, smell, and acidity; beginning to coagulate at 140° F., and soluble in water. It consists: 1, of an albuminoid substance, coagulable by pure alcohol but not by a heat of 212° F., called by him crotaline, the poisonous element; 2, of a non-poisonous albuminoid compound, coagulable both by heat and alcohol; 3, of a yellow coloring matter and an undetermined substance, both soluble in alcohol, traces of fatty matter and free acid-saline bodies, chlorine, and phosphates. No temperature from zero to 212°, nor acids and alkalis at moderate temperatures, nor alcohol, chlorine, nor iodine, destroy the poisonous property of the venom. This fluid is fatal even to the bitten snake; it destroys the vitality of the blood and its power of coagulation, as by a lightning stroke; it probably acts as a powerful sedative through

the blood on the nervous centres; hence the best antidotes are active stimulants, especially alcohol in some form; and, *vice versa*, intoxication may be neutralized by taking this poison into the stomach in the form of pills. The poison varies in intensity according to season, climate, and vigor of the animal, being most active in tropical regions and in warm weather, when it has been long retained or the animal is greatly irritated; cold-blooded animals generally suffer little from its bite, and pigs kill and devour it with impunity and avidity, their covering of fat preventing the introduction of the poison into the circulation; its virulence is soon exhausted by rapidly succeeding bites, as has been proved by experiments on chickens and rats; as its secretion goes on for some time after death, experimenters should be careful in their manipulations about the fangs and poison apparatus. Many plants and other substances are reputed to be efficacious against the bite of the rattlesnake; but none have been proved to be so when the poison fangs have actually entered the tissues. —For details on the habits of these serpents, on the anatomy of the parts concerned in the secretion and expulsion of the poison, and in the infliction of the wound, and for a full enumeration of genera and species, with illustrations and copious bibliography, see a memoir in vol. xii. of the "Smithsonian Contributions to Knowledge" (1860), by S. Weir Mitchell, M. D., and an abstract of the same in the secretary's report for 1860 (8vo, Washington, 1861).

RAUCH, Christian Daniel, a German sculptor, born in Arolsen, Jan. 2, 1777, died in Dresden, Dec. 3, 1857. He studied in Cassel, and in 1797 went to Berlin, where he was attached to the royal household till 1804, when Queen Louisa enabled him to study in Dresden and in Rome. He early became known by his bust of a daughter of Wilhelm von Humboldt and bass reliefs of "Hippolytus and Phædra," "Mars," and "Venus wounded by Diomedes." In 1813 he finished his celebrated statue of Queen Louisa, and subsequently executed hundreds of works, of which almost every considerable German city has one or more. The principal are statues of King Maximilian at Munich, Blücher at Berlin and at Breslau, Dürer at Nuremberg, Luther at Wittenberg, Kant at Königsberg, six large Victories in the Walhalla, and especially his colossal equestrian statue of Frederick the Great at Berlin, finished in 1851. His last model, that of "Moses praying together with Aaron and Hur," has been cut in marble by Albert Wolf. He held the posts of court sculptor and professor of sculpture in the academy of Berlin.

RAUCH, Friedrich August, a German philosopher, born at Kirchbracht, Hesse-Darmstadt, July 27, 1806, died in Mercersburg, Pa., March 2, 1841. He graduated at the university of Marburg in 1827, afterward studied at Gießen and Heidelberg, and in his 24th year became extraordinary professor in the univer-

sity of Giessen, and soon afterward ordinary professor at Heidelberg. Before assuming the duties of the latter appointment, he incurred the displeasure of the government by too free an expression of his political sentiments, and fled. He arrived in America in 1831, and in June, 1832, was ordained to the ministry, and called to York, Pa., to take charge of a classical school in connection with the theological seminary of the German Reformed church. In 1835 he was chosen president of Marshall college, Mercersburg, acting at the same time as professor of Biblical literature in the theological seminary, which had been removed to that place. He continued in this double office up to the time of his death. He published "Psychology, or a View of the Human Soul" (1840), and left unfinished a work entitled "Christian Ethics." A volume of his sermons was edited by the Rev. Dr. Gerhart, entitled "The Inner Life of the Christian" (Philadelphia, 1856).

RAUMER. I. Friedrich Ludwig Georg von, a German historian, born at Wörlitz, near Dessau, May 14, 1781, died in Berlin, June 13, 1873. He completed his studies at Halle and Göttingen, and was employed in the civil service from 1801 to 1811, when he became professor at Breslau, and in 1819 at Berlin, where he remained till 1853. At various periods he visited England, the United States, and other countries. In 1848 he was a member of the Frankfurt parliament, and was employed on a diplomatic mission to Paris; and he was afterward a member of the Prussian upper house till 1871. His principal works are *Geschichte der Hohenstaufen und ihrer Zeit* (6 vols., Leipsic, 1823-'5; 4th ed., 1871), and *Geschichte Europa's seit dem Ende des 15. Jahrhunderts* (8 vols., 1832-'50). His other publications include *Herbstreise nach Venedig* (2 vols., 1816); *Vorlesungen über die alte Geschichte* (2 vols., 1821; 3d ed., 1861); *Briefe aus Paris und Frankreich*, 1830 (2 vols., 1831); *Briefe aus Paris zur Erläuterung der Geschichte des 16. und 17. Jahrhunderts* (2 vols., 1831); *England im Jahr 1835* (2 vols., 1836; enlarged ed., 3 vols., 1842; English translation by Sarah Austin and H. E. Lloyd, 1836-'42); *Beiträge zur neuern Geschichte aus dem Britischen Museum und Reichsarchive* (5 vols., 1836-'9); *Italien* (2 vols., 1840); *Die Vereinigten Staaten von Nordamerika* (2 vols., 1845; English translation by W. W. Turner, "America and the American People," New York, 1846); *Briefe aus Frankfurt und Paris* (2 vols., 1849); *Antiquarische Briefe* (1851); *Vermischte Schriften* (3 vols., 1852-'4); *Lebenserinnerungen und Briefwechsel* (2 vols., 1861); *Handbuch zur Geschichte der deutschen Literatur* (4 vols., 1864-'6); and *Literarischer Nachlass* (2 vols., 1869). In 1830 he began the publication of the yearly *Historisches Taschenbuch*, which he edited till his death, and which is now continued by Riehl. **II. Karl Georg von**, a German geographer, brother of the preceding,

born at Wörlitz, April 9, 1783, died in Erlangen, June 2, 1865. He studied at Göttingen, Halle, and Freiberg. In 1810 he received an appointment in the mineralogical bureau at Berlin, and in 1811 at Breslau. In 1813-'14 he fought against the French as aide-de-camp of Gneisenau. From 1819 to 1823 he was employed both in the mining bureau and the university of Halle, and subsequently at Nuremberg till 1827, when he became professor of natural history and mineralogy at Erlangen. His chief works are: *Lehrbuch der allgemeinen Geographie* (Berlin, 1832; 3d ed., Leipsic, 1848); *Beschreibung der Erdoberfläche* (6th ed., 1866); *Palästina* (1835; 4th ed., 1860); *Kreuzzüge* (2 vols., Stuttgart, 1840 and 1864); *Geschichte der Pädagogik* (3d ed., 4 vols., 1857-'61); and his autobiography (1866). **III. Rudolf von**, a German philologist, son of the preceding, born in Breslau, April 14, 1815, died Aug. 30, 1876. He studied at Erlangen, Göttingen, and Munich, and in 1840 began to teach at Erlangen, where in 1852 he became professor of philology. Among his works are: *Gesammelte sprachwissenschaftliche Schriften* (Frankfurt, 1863); *Untersuchungen über die Urvorwandtschaft der semitischen und indoeuropäischen Sprachen* (1868 et seq.); and *Geschichte der germanischen Philosophie, vorzugsweise in Deutschland* (Munich, 1870).

RAUSCHER, Joseph Othmar von, an Austrian cardinal, born in Vienna, Oct. 6, 1797, died in November, 1875. He became successively professor of canon law and church history at Salzburg, rector of the oriental academy of Vienna, preceptor to the present emperor and the archdukes Maximilian and Charles Louis, prince-bishop of Seckau in 1849, prince-archbishop of Vienna in 1853, and cardinal Dec. 17, 1855. This last dignity was bestowed in acknowledgment of his services in bringing about the concordat of Aug. 18, 1855, between Austria and the holy see. He was foremost among the German episcopate in opposing the introduction of the question of papal infallibility, and in April, 1870, published a pamphlet arguing strongly the dangers of such a discussion. When the general debate on infallibility was closed by the presiding legates in the beginning of June, a meeting of prelates was called at his residence, at which a protest was drawn up against the act of the legates. His last speech in the council warned the fathers that fatal consequences would ensue from a declaration. He was one of the 83 bishops who voted *non placet* on July 13, and one of the 55 who signed a formal protest against the manner of proceeding. He afterward acquiesced in the decision of the majority, and promulgated the dogma for acceptance by his flock. After 1870 Cardinal Rauscher strenuously opposed the Old Catholic movement.

RAVAILLAC, François, the assassin of Henry IV. of France, born in Angoulême about 1573, executed May 27, 1610. He was first a lawyer's clerk, and then a schoolmaster. Having

been cast into prison for some offence, he fell into a gloomy fanaticism. He went to Paris, and joined the Feuillants, but was expelled as a fanatic and fool, and returned to Angoulême, where he manifested the most intense hatred of Protestantism. He determined to undertake the murder of Henry IV., whom he was taught to consider the great enemy of the Catholic faith, and went to Paris. On May 14, 1610, about 4 P. M., the king drove to the arsenal to visit Sully, who was sick. In the narrow street La Ferrière the carriage was obliged to stop, as the way was blocked up by market wagons. The king was sitting on the left side next to the duke d'Épernon, when Ravaillac, throwing himself upon the right hind wheel, struck twice at him with a dagger, the second time plunging the knife into the heart of the king. He was immediately caught with the knife in his hand, acknowledged his deed, and after a trial before the parliament of Paris was torn to pieces by horses with unexampled tortures.

RAVEE, a river of India, an eastern affluent of the Chenaub, and one of the five rivers to which the Punjaub owes its name. It rises in the Mid-Himalaya range, in the state of Kooloo, W. of the Rotang pass, about lat. $32^{\circ} 30' N.$, lon. $77^{\circ} E.$, at an elevation of about 16,000 ft. It flows S. W. about 450 m., passing the towns of Chamba, Lahore, and Tulumba. It is the main feeder of the great Baree doab canal. The railway from Lahore to Mooltan, about 40 m. below its junction with the Chenaub, almost skirts its left bank. Its width varies between 50 and 500 yards, and it attains when fullest in some places a depth of 12 ft., but it is generally fordable three fourths of the year. Its ancient Sanskrit name was Iravati, which is still preserved in the local dialect as Iraotee. Ancient Greek writers call it the Hydraotes or Hyarotis, while Ptolemy gives it the name of Adris.

RAVEN, the largest of the *corvidæ* or crow family, and the type of the genus *corvus* (Linn.). In this genus the bill is long and very strong, and arched; the nasal feathers are lengthened and reach about to the middle of the bill, and the nostrils are large, circular, and overhung behind by membrane; the gape without bristles; wings long and pointed, when closed reaching nearly to the tip of the tail and far beyond the under coverts; the second quill longer than the first, and the third and fourth the longest; primaries ten, the outer four sinuated on the inner edge; tail short and nearly even; tarsi longer than middle toe, scaled in front. The American raven (*C. carinivorus*, Bartram) is about 25 in. long with an alar extent of 50, and the bill 3 in.; the female is a little smaller, but in other respects like the male. The plumage is compact, glossy black, with violet and greenish reflections; the feathers of the chin and throat, as in all ravens, are elongated, stiffened, narrow, lanceolate, and with very distinct outlines. It is found over

the entire continent of North America from Labrador to the gulf of Mexico, in some places migratory, but in others (as at Lake Superior and in Canada) braving the cold of the severest winters; it is most abundant in rocky districts, near the banks of lakes and rivers, and in thinly peopled regions. It is generally seen alone or in pairs, but sometimes in small flocks after the breeding season; the flight is rapid, elevated, and protracted, the bird often sailing for hours at a time at a great height; on the ground the gait is grave and dignified, with frequent opening of the wings. It is truly omnivorous, but by preference carnivorous, eating small animals of all kinds, eggs and young birds, carrion, dead fish, mollusks, crustaceans, insects, nuts, and berries. It is very wary and cunning, and is rarely caught in traps or shot, but it often falls a victim to the poisoned baits set by the trappers for the fur-bearing animals. It breeds, according to latitude, between January and June, making a rude nest on inaccessible cliffs, repairing the same for years in succession; the eggs are four to six, 2 in. long, light greenish blue with numerous light purple and yellowish brown blotches, especially at the larger end; incubation lasts about three weeks, and the young remain in the nest several weeks before they are able to fly, fed at first on the half digested food disgorged by the parents; only one brood is raised in a year, and this is bravely and successfully defended against the largest birds of prey. It is easily domesticated by kindness, and becomes much attached to its master, following him like a dog; it can be taught to imitate the human voice and to pronounce a few words with great distinctness; when irritated or wounded, it strikes savagely with bill and claws. Its flesh is tough and unfit for food; it disgorges indigestible substances, as bones, hair, and feathers, like birds of prey. Like others of the genus, this species varies much in size and proportions, according to locality, those of the south, contrary to the general rule, being larger than the northern individuals of the same species; this fact has led some to think that the Colorado raven (*C. cacalotl*, Wagl.) is only a southern variety of the *C. carinivorus*, the chief differences being a slightly greater size, longer wings and tail, and a western and southern habitat exclusively. The white-necked raven (*C. cryptoleucus*, Couch), from Mexico and Texas, is about 21 in. long, with the feathers of the neck all round, back, and breast, snow-white at the base.—The European raven (*C. corax*, Linn.) very much resembles the American in size and proportions, and the two have been regarded by Audubon and others as the same, but most modern naturalists consider them distinct; it is about 26 in. long and 52 in alar extent. It is very interesting on account of its habits, and its historical, economical, and superstitious relations; it is very grave and dignified, sagacious, courageous, and powerful; its beak is as

well adapted for tearing flesh as is that of rapacious birds; though wary and distrustful, it is docile and affectionate when domesticated; it has an excellent memory, and a decidedly thievish disposition. The color is black, with steel-blue and purplish or violet reflections;

Raven (*Corvus corax*).

its form is symmetrical and its proportions are fine. It is proverbially long-lived, and has been known to attain the age of about 100 years; it is spread extensively over Europe, and allied species are found in Africa and Asia. It is voracious and omnivorous, but particularly fond of carrion, whether of flesh, fish, or fowl, dead from disease or accident; it will attack an animal of the size of a sheep if it is helpless or dying; it is said to destroy young lambs, and certainly makes great havoc among half-grown hares and rabbits, young and full-fledged birds, and eggs; when it finds a carcass the first attack is upon the eyes and tongue, and then upon the abdomen to drag out the intestines; in autumn it sometimes commits serious depredations upon barley fields. The flight is at times very high, which enables them to follow any companions which have chanced to spy their favorite food; this explains the rapid collecting of a large number in a short time; they have no special acuteness of smell, but are guided to their food by the sense of sight; the voice is a harsh and disagreeable croak. They are usually seen alone or in pairs, except when drawn together by a large carcass in the field or on the shore; the nest is made in lofty trees or in holes of inaccessible cliffs, and the same one is used year after year; a fetid odor issues from the body, probably on account of their carrion food. Farmers and shepherds like to have them breed on their premises, as they keep off eagles, cats, dogs, &c. This was considered a bird of ill omen by the ancients, and its movements were watched by the augurs with great attention;

and it has been generally looked upon with superstitious fears, on account of its black hue, mournful croak, fetid odor, and disgusting habits. It by preference inhabits the most desolate places. In America, where the crow abounds, as about Lake Superior, the raven is very rarely seen, and *vice versa*.

RAVENNA. I. A N. E. province of Italy, in Emilia, bordering on the Adriatic, Ferrara, Bologna, Florence, and Forli; area, 742 sq. m.; pop. in 1872, 221,115. It is mountainous, especially in the south, and is traversed by the Savio, Santerno, and many other streams. The principal products are rice, grain, hemp, flax, and pine, anise, and coriander seeds. It comprises the former papal legation of Ravenna, excepting the district of Imola, which has been added to Bologna, but including that of Lugo, taken from Ferrara; the other two districts are Ravenna and Faenza. II. A city, capital of the province, in a marshy plain on the river Montone, near the Adriatic, and 173 m. N. of Rome; pop. in 1872, 58,904. The principal buildings are the cathedral, of the 4th century, with fine pictures by Guido Reni; the church of Santa Maria della Rotonda, formerly the mausoleum of Theodoric, king of the Ostrogoths, N. of the city proper; the basilica of San Vitale, remarkable chiefly for its splendid mosaics; the churches of St. John the Baptist and St. John the Evangelist, built early in the 5th century by the empress Galla Placidia; and the remains of the palace of Theodosius, occupied after him by the exarchs. Among the many historical curiosities is the tomb of Dante, who died here. (See DANTE, vol. v., p. 672.) Ravenna is the seat of an archbishop, and has many convents, a museum, library, and academy of fine arts. The chief pursuits are the culture of the vine and the rearing of silkworms, with the spinning and weaving of silk. The town was once situated on the Adriatic in the midst of marshes, but it is now some distance from the sea, and separated from it by the Pineta, a remarkable forest of pines extending for many miles along the coast.—The city appears to have been founded by the Umbrians. It is not mentioned in history until a late period of the Roman republic, but during the later civil wars it held a prominent position. Augustus raised it to still greater importance by building a new port called Portus Classis, or simply Classis, capable of containing 250 ships of war, and making it the station of the fleet guarding the Adriatic. Its natural strength contributed to render it an important military post, and in A. D. 404 Honorius made it the imperial abode. On the fall of the western empire it became the capital of the Gothic kings, and it was subsequently the residence of the exarchs of the Byzantine emperors, and the whole province under their jurisdiction was called the exarchate of Ravenna. The city itself remained in the possession of the Greek emperors until taken by Luitprand, king of the Lombards, in 728, and again, after a re-

capture, by Astolphus, one of his successors, in 752. Luitprand destroyed the ancient port of Classis. When Pepin had conquered the Lombards he made a present of Ravenna to the pope, and with occasional interruptions it belonged to the Papal States till 1860. From 1441 to 1508 it was in the hands of the Venetians, but the league of Cambrai placed it again under the pope. It is celebrated for the great victory gained under its walls by the French under Gaston de Foix, who fell in the action, over the Spaniards and the troops of Pope Julius II., April 11, 1512. (See GASTON DE FOIX.)

RAVIGNAN, Gustave Xavier Delacroix de, a French preacher, born in Bayonne, Dec. 2, 1795, died in Paris, Feb. 26, 1858. He studied law, and in 1821 became counsellor to the royal court of Paris, and deputy attorney general near the tribunal of the Seine. He resigned and entered the Jesuit novitiate at Montrouge in 1822, was ordained priest in 1828, and taught theology at St. Acheul till 1830, and afterward at Brigrin the Valais till 1833. His Lenten sermon in the cathedral of Amiens in 1831 laid the foundation of his fame as a preacher. In 1836 he preached a Lenten sermon in Paris, and shortly after succeeded Lacordaire in the pulpit of Notre Dame, which he occupied till 1848. In 1844 the attacks made on the Jesuits in the public press and the legislature induced him to publish an apologetic work entitled *De l'existence et de l'institut des Jésuites* (7th ed., 1855). In 1837 he founded a house of his order in Bordeaux, which he governed for four years; and in 1848 he became superior of the Parisian residence in the rue de Sèvres, the interval being filled up by charity sermons, and the foundation and direction of various charitable and pious associations, all aiming at the improvement of the common people. In 1851 he visited London during the universal exhibition, and gave a course of lectures. In 1852 he wrote at the instigation of Pius IX. his *Clément XIII. et Clément XIV.*, a history of the suppression of the Jesuits, designed to counteract the extreme views of Theiner and Crétineau-Joly. His life was written by Poujoulat (1858) and by Père de Ponlevoy (2 vols., 1860; English translation, New York, 1873).

RAWDON, Lord. See HASTINGS, FRANCIS.

RAWLE, William, an American lawyer, born in Philadelphia, April 28, 1759, died April 12, 1836. He studied law in New York, London, and Paris, and commenced practice in Philadelphia in 1783. He was United States district attorney under Washington, was president of the Pennsylvania historical society, and chancellor of the associate members of the bar of Philadelphia. He published "A View of the Constitution of the United States" (1829).

RAWLINS, a N. W. county of Kansas, formed since 1870; area, 900 sq. m. It borders on Nebraska, and is drained by Beaver and Sappa creeks, affluents of the Republican river.

RAWLINSON. I. Sir Henry Creswicke, an English archæologist, born at Chadlington, Oxford-

shire, in 1810. In 1826 he entered the military service of the East India company, and served in Bombay till 1833, and subsequently in the Persian army. In 1835, while stationed at Kermanshah, he began to study the cuneiform inscriptions at Mt. Elvend. In 1837 he copied the first column of the great Behistun inscription and four minor inscriptions, and on Jan. 1, 1838, submitted a report to the Asiatic society in London. The outbreak of the war in Afghanistan interrupted his labors. After exploring various regions of central Asia, he was for some time political agent at Candahar, and returned in the same capacity to Bagdad. In 1844 he forwarded to London complete copies of the Persian portion of the Behistun inscription, of which the Asiatic society published facsimiles in 1846, and which included more of the cuneiform writing of the first kind than the aggregate of all other inscriptions then known in Europe. (See CUNEIFORM INSCRIPTIONS.) He was consul at Bagdad from 1844 to 1851, and consul general till 1855. After returning to England he was knighted and appointed a director of the East India company. In 1858 he was elected to parliament for Reigate, and from 1859 to 1860 he was minister at Teheran with the rank of major general. He represented Frome in parliament from 1865 to 1868, when he was reappointed member of the council for India. In 1871-'3 he was president of the royal geographical society, which office he again holds (1875); and he also presides over the society of Biblical archæology. Besides his numerous contributions to the journals of Asiatic societies and other learned periodicals, he has published "On the Inscriptions of Assyria and Babylonia" (London, 1850); "Outline of the History of Assyria, as collected from the Inscriptions discovered by A. H. Layard in the Ruins of Nineveh" (1852); "Memorandum on the Publication of the Cuneiform Inscriptions" (1855); contributions to his brother's "Herodotus" (4 vols., 1858-'60); "A Selection from the Historical Inscriptions of Chaldaa, Assyria, and Babylonia" (fol., 1861); in conjunction with Norris, "The Cuneiform Inscriptions of Western Asia" (3 vols., 1861-'70, lithographed for the British museum); and jointly with George Smith, "A Selection from the Miscellaneous Inscriptions of Assyria" (fol., 1870). In 1874-'5 appeared his "England and Russia in the East," a series of papers on the political and geographical condition of central Asia.

II. George, an English historian and orientalist, brother of the preceding, born at Chadlington in 1815. He graduated at Oxford in 1838, became a fellow and tutor of Exeter college, and was Bampton lecturer from 1859 to 1861, and Camden professor of ancient history from 1861 to 1874, when he became canon of Canterbury cathedral. He has published "Historical Evidences of the Truth of the Scripture Records" (London, 1860); "The Contrasts of Christianity with the Heathen and Jewish

Systems" (1861); in conjunction with his brother Henry and Sir J. G. Wilkinson, an annotated translation of "Herodotus" (4 vols., 1858-'60); and "Historical Illustrations of the Old Testament" (1871). His most celebrated works are "The Five Great Monarchies of the Ancient Eastern World, or the History, Geography, and Antiquities of Chaldæa, Assyria, Babylonia, Media, and Persia" (4 vols., 1862-'7; 2d ed., republished in New York, 1871), "A Manual of Ancient History" (1869), and "The Sixth Great Oriental Monarchy, or the Geography, the History, and the Antiquities of Parthia" (1873).

RAY, the name of the plagiostome, chondropterygian, or cartilaginous fishes of the suborder *raia*, popularly called skates. The numerous families are characterized by great flatness and width of the body, the latter arising principally from the extreme expansion of the pectoral fins; the skull is flat, the upper wall generally membranous, and movably articulated, as in sharks, by two condyles and an intervening space with the spine; anteriorly the head ends in a tapering cartilage which supports the snout; spout holes or spiracles for respiration and eyes on the dorsal aspect, the latter without lids or with an upper adherent one; on the ventral surface are five slit-like gill openings, before the ventrals and under the pectorals; the scapular arch is complete above and below, supporting the long, jointed, cartilaginous rays of the pectorals; between this and the pelvic arch, supporting the ventral, lie the abdominal viscera, and between it and the narrow skull are the branchial apparatus and the vascular centres. The spiracles are openings by which the water may pass from the upper surface of the head into the mouth cavity, and are found in perfection only in those species which live upon the bottom; the eyes being above, and the fins feeble, they seek their prey by the sense of touch in the snout, stirring up the mud and sand while feeding; their gills would thus be injured by gritty materials were the water taken in from below by the mouth; in the rays the comparatively pure water enters from above by the spiracles, and passes out at the branchial openings, or *vice versa*. The development of these openings is in direct proportion to that of the sense of smell, and in inverse proportion to that of sight. (See "Proceedings of the Boston Society of Natural History," vol. xvii., November, 1874.) In the torpedoes the cellular galvanic batteries occupy the spaces between the skull and the pectorals; and a homologous rudimentary apparatus has been found in the tail of common skates, showing the adherence to a general plan of structure irrespective of function. The tail in some is fleshy and tapering, in others slender and cartilaginous, in others elongated like a whip lash, and in others armed with lancet-shaped spines on the upper surface, making a very formidable weapon. The gills consist of membranous folds on plane surfaces, and the arterial bulb

has from two to five transverse rows of semilunar valves. The reproductive secreting organs are compact and oblong, the efferent tubes communicating with the ureters and ending in a rudimentary organ in the cloaca; the claspers are present in the males, as appendages to the posterior edge of the anal fin, fissured toward the end, leading to a blind subcutaneous sac well lubricated with mucus and the secretion of a glandular body; the ovaria are comparatively small, and the ova are larger and fewer than in common fishes, and more as in birds; most of the genera are viviparous, but some of the genus *raia* are oviparous. The claspers are not mere organs of prehension; they may be so rotated as to bring an opening in them opposite to the spermatic duct, and may, according to Agassiz ("Proceedings of the Boston Society of Natural History," vol. vi., p. 377, May, 1858), be introduced into the oviducts, and reach the glands there situated for the formation of the egg case. They are true intromittent or copulatory organs. The egg cases of the skate are often seen on our beaches after a storm; they are quadrangular, about two inches by one, brown and leathery, each corner prolonged into a tubular process; they look somewhat like pillow cases, and are often called sailors' purses and skates' barrows. The young within the egg has no investing membrane, and the yolk seems to bear no relation in size to that of the embryo; water for respiration is admitted and ejected through the corner prolongations, and the young fish escapes through a transverse fissure at one end. The horny egg case may be formed in each oviduct, and is surrounded by a glandular enlargement which secretes its materials; it is formed before the egg descends into it, in the shape of a pocket open above for the reception of the egg, which must be impregnated in the ovary, contrary to the usual order of things, in which the yolk is enclosed before the shell is formed; as the eggs are found to be of different sizes and various degrees of development in the ovary, it is probable that several years are required for their maturity; these peculiarities show the propriety of placing the skates (with the sharks forming the division of selachians of Aristotle and Agassiz) in a class by themselves. The teeth of the rays are generally tubercular, in close quincunx order like a mosaic pavement. Disgusting as is the form of the rays, their flesh is esteemed a delicacy in England and France, though it is rarely eaten in America except by those of European origin; it is tough when first caught, but becomes tender by being kept several days; with us it is most commonly used as bait for lobster pots, or for manure. Of the families of rays, the *pristidæ* and *torpedinidæ* will be described under **SAWFISH** and **TORPEDO** respectively; the *cephalopteridæ* have been noticed under **DEVIL FISH**.—The family *rhinobatidæ* are intermediate between sharks and rays, having the form of body, position of fins, thick, fleshy tail, and smallness of pectorals of the

former; the anterior part of the body forms a disk by the union of the pectoral fins with the snout, the latter divided from the former by a furrow, whence these have been called beaked rays; the first dorsal is over the ventrals; the caudal bilobed, with the upper lobe the larger, and the keel of the sides continued along it; margins of mouth generally undulated, three protuberances of the under jaw fitting into corresponding indentations in the upper; nostrils longitudinal near the mouth, with flaps.—In the family *raiidæ* or the typical rays, the

Smooth Skate (*Raia levis*).

snout is more or less pointed, the disk of the body and pectorals usually rhombic; tail slender, with two small dorsals near the end and sometimes a caudal; spiracles near the eyes; mouth curved, with the convexity forward; teeth of males with a central cusp in spawning time; skin either smooth or studded with prickles pointing backward, sometimes with spines on the dorsal ridge and sides of tail. This family includes the genus *raia* (Cuv.), with about 30 species, embracing the best known in America and in Europe, and such as are commonly eaten in the latter. The smooth ray or common skate of the northern coast of America is the *raia levis* (Mitch.); it is of a uniform light brownish color above, and dingy white below; the female is marked above with blackish spots; it attains a length of from 3 to 5 ft., and a weight of 200 lbs.; it is found from New York to the British provinces; the body is generally smooth, but there are small spines about the orbits, on the anterior edge of the pectorals, and on the tail; the snout is blunt, and the teeth in compact rows, six-sided and nearly smooth. Its flat form is peculiarly adapted for life on or near the bottom; the usual mode of progression is by a gentle undulating movement of the pectorals, intermediate between flying and swimming; when in pursuit of prey or escaping from its enemies, the motions are rapid. The young are produced twice a year, in spring and in autumn, deposited in thin, horny, nearly quadrangular cases. Its flesh is said by Mr. Perley to be extensively consumed, and the fleshy part of the pectorals to be beautifully white and delicate; it is usually dressed in long thin slips, rolled like ribbon. On the coast of New England, Nova Scotia, and New

Brunswick it is frequently taken by the cod fishers, being generally hooked by its pectorals; it is pulled up like a dead weight to near the surface, unless caught by the mouth or head, and struggles violently on being drawn out. It feeds on fish, crustaceans, and mollusks, and is very voracious; it digs up clams with its powerful spade-like snout, crushing them easily with its rolling flattened teeth. The skin is covered with an abundant tenacious slime. There are eight or nine species in European waters, some attaining a weight of 200 lbs. The sharp-nosed ray (*R. oxyrhyncha*, Linn.) attains a length of 6 ft.; this is the favorite species in the French markets. The common skate or ray (*R. batis*, Linn.) is a large species, with a granulated skin above; the color is brown above, cinereous below or grayish white with black specks. Several species are common in the London market, where the females are known as maids.—In the family *trygonidæ* or sting rays the tail is slender, often whip-like, naked or bearing one or more barbed spines; no caudal fin; pectorals large, uniting in front of the head; spiracles large and close behind the eyes; teeth small, transversely elliptical, and ridged; skin either smooth or prickly, but without prickles on the pectorals. The American whip sting ray (*pastinaca hastata*, De Kay) occurs on the coast of the middle states, in Long Island sound, and sometimes on

American Sting Ray (*Pastinaca hastata*), under surface.

the coast of Massachusetts; it is olive brown above, and white below; it attains a length of from 5 to 8 ft., including the tail. It is not uncommon on the shores of New Jersey, where it is caught both by hook and seine, varying in size from a breakfast plate to a width of 4 ft. and a tail of 5 ft.; the fishermen always cut off the tail at once, to prevent wounds from its spines, which, being serrated, produce extensive lacerations accompanied by severe inflammation. The principal use made of this species, and indeed of all the rays in

this country, is to extract the oil from the liver, which, with that from this organ in sharks, is employed for various domestic and medicinal purposes. The European sting ray is common in the Mediterranean and on the southern Atlantic coast; it was well known to the ancients, who thought it capable of inflicting poisoned wounds; it twists its long tail around its prey or its enemies, causing very severe lacerated wounds; its flesh is not eatable. The spines of some of the species of this genus are used by savages as arrow and spear heads.—In the family *myliobatidæ* or eagle rays, the head is more elevated than in the other families, projecting as far as the gills, without fin rays on its sides, but with a kind of cephalic fin in front of the skull making the point of the disk; the pectorals are very large and wing-like; the tail is long and slender, with a small dorsal and strong spine; the mouth is transverse, with the dental plates reaching far back into the cavity of the mouth; the teeth are like a mosaic pavement, large and even, in several rows forming a convex surface; the eyes and spiracles are on the sides of the head, and a broad ridge runs between the two; the interrupted pectorals on the sides of the head are a family character. In the genus *myliobatis* (Cuv.) the nasal membrane is square, and the pectorals end in an angular projection; the teeth form long hexagonal plates in the middle, with two or three short or equal rows on the sides. The *M. acuta* (Ayres) is found on the Massachusetts coast and in Long Island sound, and attains a length of about 4 ft.; the body is smooth and reddish brown above, whitish below; tail very slender and armed with spines. The eagle ray of the Mediterranean (*M. aquila*, Risso) grows large; the wounds made by its spines are much dreaded by fishermen. Several species are found in the seas of the warm parts of the globe. In *rhinoptera* (Kuhl) the nasal membrane is notched; the central teeth are the largest, the three lateral rows growing smaller and smaller externally. In *ætobatis* (Müll.) the nasal membrane is lobed, which would embrace many species of *rhinoptera* as usually defined, and the pectorals are rounded; the teeth form a single row of simple arched plates, without lateral rows. In *zygobatis* (Ag.) the nasal lobes and the pectorals are as in the preceding genus; the central rows of teeth are much the largest, the first lateral about half as large, and the two external very much smaller. In *goniobatis* (Ag.) the palate is broadest behind, and the plates are obtusely angular, with their rounded edges forward.—There is hardly a family of fishes in the classification of which more confusion reigns than that of the rays; naturalists see them only in rare instances, and almost always single specimens at a time; there can be little doubt that the two sexes of the same species have in some instances been made into distinct species. Even our most common rays are very imperfectly known, and

the genus *raia* embraces many species which are not congeners.—For details on the embryology of the rays, see Prof. J. Wyman's paper in "Memoirs of the American Academy," vol. ix., 1867, and Mr. Putnam's in the "American Naturalist," vol. iii., 1870.

RAY, a N. W. county of Missouri, bordered S. by the Missouri river; area, about 570 sq. m.; pop. in 1870, 18,700, of whom 1,833 were colored. It has an undulating surface, covered with forests and prairies, and a generally fertile soil. It is intersected by the St. Louis, Kansas City, and Northern railroad. The chief productions in 1870 were 187,736 bushels of wheat, 1,245,233 of Indian corn, 177,461 of oats, 39,114 of potatoes, 6,610 tons of hay, 190,355 lbs. of tobacco, 42,374 of wool, 122,774 of butter, and 11,085 gallons of sorghum molasses. There were 9,009 horses, 2,155 mules and asses, 5,469 milch cows, 11,176 other cattle, 20,580 sheep, and 38,523 swine; 2 flour mills, and 13 saw mills. Capital, Richmond.

RAY, Isaac, an American physician, born in Beverly, Mass., in January, 1807. He graduated at the Harvard medical school, and began the practice of medicine in Portland, Me., in 1827. In 1829 he removed to Eastport, Me., in 1841 was appointed superintendent of the state insane hospital at Augusta, and in 1845 superintendent of the Butler hospital for the insane at Providence, R. I., which office he filled till 1866. He subsequently removed to Philadelphia. He has published "Conversations on Animal Economy" (Portland, 1829); "Medical Jurisprudence of Insanity" (Boston, 1838; 5th ed., enlarged, 1872); "Education in relation to the Health of the Brain" (1851); and "Mental Hygiene" (1863).

RAY, John (or WRAY, as he at one time spelled his name), an English naturalist, born near Braintree, Essex, in 1628, died in 1705. He graduated at Trinity college, Cambridge, became a fellow in 1649, professor of Greek in 1650, and mathematical tutor in 1652. His health being impaired, he travelled over the greater part of England, Wales, and Scotland, studying their botany and zoölogy. At the restoration he took orders, but never held any church preferment, and two years later resigned his fellowship, as he could not conscientiously subscribe to the act of uniformity. After this he resided chiefly at Middleton hall, in Warwickshire. From 1663 to 1666 he travelled with Mr. Willughby on the continent, and he published an account of this tour in 1673. In 1667 he was elected a fellow of the royal society. Among his most important works are: *Catalogus Plantarum Angliæ* (1670), the foundation of all English floras; *Methodus Plantarum Nova* (1682), in which he proposed a new method of classification, which, altered and amended by himself, formed the basis of the method of Jussieu; and *Historia Plantarum* (3 vols., 1686-1704). He edited Willughby's works on the animal king-

dom, and published several of his own. His "Collection of English Proverbs" (1672) has passed through many editions, and was reprinted with additions by H. G. Bohn (London, 1850). A revised edition of his "Glossaries of North and South Country Words," by Skeat, was published in 1874 by the English dialect society. The Ray society of London, formed in 1844 for the publication of works on natural history, took its name from him, and has published "Memorials of John Ray," edited by E. Lankester, M. D. (1844).

RAYER, Pierre François Olive, a French physician, born at St. Sylvain, Normandy, March 8, 1793, died Sept. 10, 1867. He graduated in medicine at Paris in 1818, and soon acquired an extensive reputation both as a scientific man and as a practitioner. In 1832 he was appointed physician-in-chief to the hospital of La Charité, and in 1852 was attached to the medical service of the imperial household. He published *Sommaire d'une histoire abrégée de l'anatomie pathologique* (1818); *Mémoire sur le delirium tremens* (1819); *Histoire de l'épidémie de suette miliaire qui a régné en 1821 dans l'Oise et le Seine-et-Oise* (1822); *De la morve et du farcin chez l'homme* (1837); *Traité théorique et pratique des maladies de la peau* (2 vols., 1826-'7; new ed., 3 vols., 1835); and *Traité des maladies des reins et des altérations de la sécrétion urinaire* (3 vols., 1837-'41). The last two were his most important works.

RAYMOND, Henry Jarvis, an American journalist, born in Lima, Livingston co., N. Y., Jan. 24, 1820, died in New York, June 18, 1869. He worked on his father's farm, at the age of 16 taught a country school, and graduated at the university of Vermont in 1840. He then studied law for a year in New York, and became assistant editor of the "Tribune" on its establishment by Mr. Greeley in 1841, having previously contributed to the "New Yorker," edited by the same journalist. He was remarkably accurate and successful as a reporter, and in 1843 joined the staff of the "Courier and Enquirer," in which journal he had a controversy with Greeley on Fourierism, which was published in a pamphlet. He was elected by the whigs to the state assembly in 1849, was reelected in 1850, and became speaker. In 1851 he severed his connection with the "Courier and Enquirer," and founded (Sept. 18) the "New York Times." In the whig national convention at Baltimore in 1852, in the face of violent opposition, he delivered a long address setting forth the northern views of the public questions then at issue. In 1854 he was elected lieutenant governor of New York. He was prominent in organizing the republican party, and wrote its "Address to the People" issued by the convention at Pittsburgh in February, 1856. He warmly supported the government in the civil war, and in 1864 was elected to congress, where he advocated the reconstruction policy of President Johnson. He published "History of the Administration

of President Lincoln" (12mo, 1864; enlarged, "Life and Public Services of Abraham Lincoln," 8vo, 1865), and numerous addresses.

RAYMOND, John T. See supplement.

RAYMOND, Rossiter Worthington, an American mining engineer, born in Cincinnati, April 27, 1840. He graduated at the Brooklyn polytechnic institute in 1858, and afterward spent three years in study at Heidelberg, Munich, and Freiberg. In 1864 he began practice in New York as a consulting engineer, and he has been since 1867 editor of the "American Journal of Mining" (afterward the "Engineering and Mining Journal"), since 1868 United States commissioner of mining statistics, and since 1870 lecturer on economic geology in Lafayette college, Easton, Pa. He was elected a vice president of the American institute of mining engineers in 1871, and president in 1872, '73, and '74. He has published annual reports of mining statistics from 1869 to 1875 inclusive, several of which have been republished as separate works; "The Children's Week," a volume of short stories (1871); "Brave Hearts," a novel (1873); and "The Man in the Moon and other Stories" (1874).

RAYMOND VI., of Toulouse. See ALBIGENSES.

RAYNAL, Guillaume Thomas François, a French historian, born at St. Geniez, Guienne, April 12, 1713, died near Paris, March 6, 1796. He was educated at a college of the Jesuits, became a priest, and for some time taught theology and preached. He went to Paris in 1747, and became an assistant clergyman at the church of St. Sulpice; but he soon gave up the ministry, associated with the "philosophers," and became director of the *Mercur de France*. He published various historical works, and, with the assistance of Diderot and others, prepared anonymously an *Histoire philosophique et politique des établissements et du commerce des Européens dans les deux Indes* (4 vols. 8vo, 1770). A second edition, containing attacks upon religion and government, was interdicted on Dec. 19, 1779; and when it appeared under his name at Geneva (5 vols. 4to, with atlas, 1780), a warrant was issued for his arrest, which he avoided by leaving France, and the parliament ordered his book to be burned by the executioner (May 25, 1781). In the same year he published his *Tableau et révolutions des colonies anglaises dans l'Amérique Septentrionale* (2 vols. 12mo), which was immediately translated into English, and the blunders of which were pointed out in a pamphlet by Thomas Paine. For several years Raynal wandered in foreign countries, and was finally permitted to return home in 1788; in 1790 the sentence of the parliament against his *Histoire philosophique* was reversed. The next year Raynal addressed to the president of the constituent assembly a letter denouncing the disorders committed in France in the name of liberty, and regretting that he "was one of those who, by expressing in their works a generous indignation against arbitrary power, had

been perhaps the means of putting weapons into the hands of licentiousness and tyranny."

RAYNOUARD, François Juste Marie, a French author, born in Brignolles, Provence, Sept. 18, 1761, died at Passy, near Paris, Oct. 27, 1836. Elected an assistant deputy to the convention, he sided with the Girondists, and after their fall was detained in prison till the revolution of Thermidor (July 27, 1794). In 1803 he obtained a prize at the French academy for a poem entitled *La vertu nécessaire dans les républiques*; and in the following year another for his *Socrate dans le temple d'Aglauré*. In 1805 his tragedy *Les templiers* was very successful. He was a member of the corps législatif from 1806 to 1813, and was elected a member of the French academy in 1807. During the hundred days Raynouard was offered the title of councillor of the university and the post of minister of justice, both of which he declined. He published *Choix de poésies originales des troubadours* (6 vols. 8vo, Paris, 1816-'21). His *Lexique roman, ou Dictionnaire de la langue des troubadours, comparée aux autres langues de l'Europe latine*, was posthumously published (6 vols. 8vo, 1838-'44). He was elected perpetual secretary of the French academy in 1817, but declined the usual salary attached to this office. Soon afterward, to save his brother from bankruptcy, he voluntarily gave up all his property.

RAZOR FISH (*xyrichthys*, Val.), an acanthopterygian genus belonging to the family of *cyclo-labridæ*. The body is compressed and covered with large scales, the lateral line interrupted; the profile is almost vertical, the forehead trenchant, and the eyes high up; the sharpness of the head is not owing to the interparietal crest as in *coryphæna* (the dolphin of sailors), but to the ethmoid and intermaxillaries growing directly downward, the lower jaw being

Mediterranean Razor Fish (*Xyrichthys cultratus*).

horizontal and of ordinary length; the cheeks are scaleless, and the snout smooth and blunt; the dorsal is long and of uniform height; the teeth are in one row, conical, largest in the middle; the palate and tongue are smooth, but the pharynx is furnished with small and pavement-like teeth; the intestinal tube is simple, without stomachal dilatation and pancreatic cæca; the air bladder is large, pointed in front. The type of the genus is the razor fish of the Mediterranean (*X. cultratus*, Val.); it is about 8 in. long, reddish, variously striped with blu-

ish; its flesh is highly esteemed as a delicate food; it lives solitary, on sandy bottoms near the shores, feeding on such fish and mollusks as its very small mouth enables it to swallow. About a dozen other species, of the same size, are found in the East and West Indies, among the Pacific islands, and on the coast of South America, where their flesh is eaten; in some the three anterior rays of the dorsal are detached and far forward, forming two dorsals.

RAZOR SHELL (*solen*, Linn.), the type of the lamellibranchiate family of *solenidæ*. The genus is characterized by two adductor muscles, the mantle open anteriorly and produced into two short united siphons, the branchiæ attached to the lower; the foot is long and club-shaped; the shells are elongated, equivalve, and gaping at both ends; the hinge has two or three compressed teeth in each valve, and is nearly terminal; the ligament is long and external. The common razor shell of our

Common Razor Shell (*Solen ensis*).

coast is the *S. ensis* (Linn.), of a scabbard shape, about 6 in. long and an inch high, with rounded ends, white within and covered outside by a glossy yellowish or brownish green epidermis. It is found on sandy beaches near low-water mark, where it burrows beneath the surface, whence it is sometimes displaced by storms; it descends into the sand with astonishing rapidity; the animal is cylindrical, longer than the shell, and is often used as food under the names of long claw, knife handle, and razor fish. The *S. siliqua* and *S. curtus* of Europe have similar habits, sinking vertically in the sand, foot downward; their burrows are sometimes 2 ft. deep, and they ascend and descend in them very quickly by widening or narrowing the foot. They are used as food, and as bait for cod and haddock; their burrows may be known by small orifices like keyholes, into which the fishermen put a little salt; this so irritates the tubes that the animal ascends near the surface, and is dragged out with an iron hook. They are found in almost all seas.

RAZZI, Giovanni Antonio, called IL SODOMA, an Italian painter, born in Vercelli, Piedmont, about 1479, died in Siena, Feb. 14, 1554. He formed his style on that of Leonardo da Vinci, and was early employed by Pope Julius II. to execute a series of works in the Vatican, afterward in part obliterated to make room for frescoes of Raphael. In the Chigi palace, now Farnesina, he painted in fresco the "Marriage of Alexander and Roxana" and the "Family of Darius." His best works are at Siena, including the "Adoration of the Magi" in the church of S. Agostino, and the "Flagellation" in the convent of S. Francisco.

RÉ, or **Rhé**, an island of France, in the bay of Biscay, forming part of the department of Charente-Inférieure, and separated from La Rochelle by a channel about 2 m. wide; area, about 30 sq. m.; pop. about 18,000. The island is inaccessible on the S. W., but the N. E. coast is strongly indented and forms several harbors. The inhabitants are engaged in commerce and the fisheries, the production of salt, and the manufacture of wine, brandy, and vinegar. The chief town, St. Martin de Ré, on the N. E. coast (pop. in 1872, 2,740), is strongly fortified. From its commanding position near La Rochelle, the isle of Ré was of great military importance in Richelieu's final struggle with the Huguenots. In 1627 the duke of Buckingham led a powerful expedition against it. He landed on July 20, and continued the attack for more than three months, but was finally forced to abandon it.

REACH, **Angus Bethune**, a British author, born in Inverness, Scotland, Jan. 23, 1821, died Nov. 25, 1856. He became about 1850 a reporter on the staff of the London "Morning Chronicle," composed much for the stage, and published "Claret and Olives: from the Garonne to the Rhône" (1852); two romances, "Clement Lorimer" (1849), and "Leonard Lindsay," a story of a buccaneer (1850); "Men of the Hour, in three Parts: Bores, Tuft Hunters, the Bal Masqué" (1856), &c.

READ, **George**, a signer of the Declaration of Independence, born in Cecil co., Md., Sept. 18, 1733, died in New Castle, Del., Sept. 21, 1798. He studied law at Philadelphia, was admitted to the bar at the age of 19, began practice at New Castle, and in 1763 was appointed attorney general for the three lower counties on the Delaware, the designation by which the present state of Delaware was then known. In 1774 he was elected to congress, of which he continued to be a member, with a brief interval, till near the close of the revolution. When the question of independence was first agitated, Mr. Read opposed it as premature, but was afterward among its most zealous supporters. In 1776 he was president of the convention that formed the first constitution of Delaware, of which he was the author, and under which he was chosen vice president, and served for a short time as president during the captivity of the regular incumbent. In 1782 he was made judge of the United States court of appeals in admiralty cases. He represented Delaware in the convention that framed the constitution of the United States, was the first senator chosen under it for that state, and retained his seat till 1793, when he was made chief justice of Delaware.

READ, **Nathan**, an American inventor, born at Warren, Worcester co., Mass., July 2, 1759, died near Belfast, Me., Jan. 20, 1849. He graduated at Harvard college in 1781, and was tutor there for four years. In 1796 he established, with others, the Salem iron foundry,

and invented a machine, patented in January, 1798, for cutting and heading nails at one operation. From 1800 to 1803 he was a member of congress. In 1807 he removed to Belfast, Me., and for many years was chief justice in the court of Hancock co. He was the author of many inventions, was one of the first to experiment with steam for navigation, and invented multitubular boilers and high-pressure engines. He also invented a method of equalizing the action of windmills, by accumulating the force of the wind by winding up a weight; a plan of using the force of the tide by means of reservoirs alternately filled and emptied in such a way as to produce a constant stream; different forms of pumping engines and threshing machines; and a plan for using the expansion and contraction of metals, multiplied by levers, for winding up clocks and other purposes. He was a member of the academy of arts and sciences.—See "Nathan Read, his Inventions," &c., by his nephew David Read (1870).

READ, **Thomas Buchanan**, an American artist and poet, born in Chester co., Pa., March 12, 1822, died in New York, May 11, 1872. At the age of 17 he entered the studio of a sculptor in Cincinnati. In 1841 he removed to New York, and after a few months to Boston, where he began his career as a painter. He contributed poems to the Boston "Courier" in 1843 and 1844, and in 1846 settled in Philadelphia. In 1850 he went to Florence, and with occasional visits to America resided in Italy till the spring of 1872, when he returned to America, but died soon after his arrival. His most popular pictures are portraits. He published "Lays and Ballads" (Philadelphia, 1848); "The New Pastoral" (1855); "The House by the Sea" (1856); "The Wagoner of the Alleghanies" (1862); "A Summer Story, and other Poems" (1865); and "Poetical Works" (3 vols., Philadelphia, 1866).

READE, **J. Charles**, an English novelist, born at Ipsden, Oxfordshire, in 1814. He graduated in 1835 at Magdalen college, Oxford, where he was elected to one of the Vinerian fellowships in 1842. In 1843 he was called to the bar by the society of Lincoln's Inn, but soon after gave his attention wholly to literature. In 1847 he received the degree of D. C. L. from his university. Among his earliest literary efforts was a drama in five acts, entitled "Gold," which appeared in 1850. In 1852 he published his first story, "Peg Woffington," which immediately gave him rank as a writer of fiction, and in the following year "Christie Johnstone," which met with still greater favor. These stories are simple in plot and unpretentious in design, but are full of dramatic force, rich in incident, and marked by a peculiar tenderness and pathos. In 1854, in conjunction with Mr. Tom Taylor, he published a volume of plays, containing "Masks and Faces," the plot of which is identical with that of "Peg Woffington," "Two Loves and a Life,"

and "The King's Rival." "Clouds and Sunshine" and "Art, a Dramatic Tale," two novellettes, appeared in 1855. All these works were received with a flattering welcome, and in 1856 he published a more ambitious novel, entitled "It is Never too Late to Mend," in which he aimed to show the possibility of the reformation of a criminal. This, which was the first of a series of romances, each written to illustrate some social or public wrong, aroused attention to the brutalities of the English prison system, and was instrumental in effecting their amelioration. His later works are: "The Double Marriage, or White Lies," "The Course of True Love never did run Smooth," "Propria Quæ Maribus, and the Box Tunnel" (1857); "Cream: Jack of all Trades," and the "Autobiography of a Thief" (1858); "Love me Little, Love me Long," and "A Good Fight and other Tales" (1859); "The Eighth Commandment" (1860); "The Cloister and the Hearth, or Maid, Wife, and Widow" (1861); "Hard Cash" (1863); "Griffith Gaunt, or Jealousy" (1866); "Foul Play," in connection with Dion Boucicault (1868); "Put Yourself in his Place" (1870); "A Terrible Temptation" (1871); "The Wandering Heir" (1872); "A Simpleton: a Story of a Day" (1874); and "A Hero and a Martyr" (1875). Of these, "The Cloister and the Hearth" incorporates the greater part of a previous story, "A Good Fight," but the plot soon changes and justifies the secondary title of "Maid, Wife, and Widow." The chief characters, Gerard and Margaret, are the parents of Erasmus. "Hard Cash" was written with the object of calling attention to the abuses of lunatic asylums; and so forcibly did he put the facts which he had gathered that it awakened official investigation and led to a change in the English lunacy laws. "Put Yourself in his Place" is an exposure of the system of terrorism, vulgarly called "rattening," practised by the trades unions in English manufacturing towns for the intimidation of independent workmen. Many of Mr. Reade's stories have been successfully dramatized, and nearly all of them have been translated into the different languages of Europe. Mr. Reade's style is characterized by great terseness and vigor, and by a wealth of incident which few writers of fiction have possessed; and though marred by occasional peculiarities, which in some instances degenerate into literary trickery, it has won him great popularity and a place among the foremost novelists of the age. **II. William Winwood**, an English traveller, nephew of the preceding, born at Ipsden, Oxfordshire, in 1839, died at Wimbledon, April 24, 1875. He visited the west coast of Africa first in 1862-'3, and on his return published "Savage Africa: a Narrative of a Tour in Equatorial, Southwestern, and Northwestern Africa" (1863). In 1868-'70 he again visited the west coast, penetrated inland by a new route from Sierra Leone to the source of the Niger, established friendly relations be-

tween that colony and the native powers 450 m. from the coast, and proved that the Niger has its rise in the same range of mountains as the Senegal and the Gambia. (See NIGER.) He soon after published "The Martyrdom of Man" (1872) and "The African Sketch Book" (1873). In 1873-'4 he accompanied the Ashantee expedition as special correspondent of the London "Times," and incurred the disease which resulted in his death. His "Story of the Ashantee Campaign" was published in 1875. Mr. Reade was also the author of several novels: "Charlotte and Myra" and "Liberty Hall, Oxon." (1859); "The Veil of Isis, or the Mysteries of the Druids" (1861); "See-Saw, by Francesco Abati, edited by W. W. Reade" (1865); and "The Outcast" (1875).

READING, a city and the capital of Berks co., Pennsylvania, on the E. bank of the Schuylkill river, here crossed by three bridges, and on the Schuylkill and Union canals, at the intersection of several branches of the Philadelphia and Reading railroad with the Wilmington and Reading line, 54 m. E. of Harrisburg and 58 m. N. W. of Philadelphia; pop. in 1800, 2,385; in 1810, 3,463; in 1820, 4,352; in 1830, 5,859; in 1840, 8,410; in 1850, 15,743; in 1860, 23,162; in 1870, 33,930, of whom 3,871 were foreigners. It is very pleasantly situated on an elevated and ascending plain, backed on the east by Penn's Mount, and on the south by the Neversink mountain, from both of which flow streams of pure water, abundantly supplying the city. It is regularly laid out, well built, and kept neat and cleanly. The streets cross each other at right angles, and in the centre is a square on which are the chief hotels and stores. The court house is a very handsome edifice with a fine portico, sustained by six columns of red sandstone. Other public buildings are the city hall, county jail, opera house, and academy of music. Of the churches the most conspicuous are Trinity (German Lutheran), an antique building with a spire 210 ft. high, and Christ (Episcopal), an imposing Gothic edifice of red sandstone with a spire 202 ft. high. Reading is surrounded by a rich farming country, with which it has a very important trade. The inhabitants of this district are chiefly of German origin, and a dialect of German, known as Pennsylvania Dutch, prevails extensively among them. The city is especially noted for its manufactures, among which the production and working of iron hold the first rank. Much of the ore is obtained from Penn's Mount. The chief establishments are 6 furnaces, 2 forges, 7 founderies, 5 rolling mills, a nail factory, 15 machine shops, 3 manufactories of iron ware of various sorts, 3 of steam boilers, 2 of nuts and bolts, and 3 of iron pipe. There are also a cotton mill, 13 shoe factories, 8 tanneries, 6 breweries, 9 brick factories, 9 manufactories of furniture, 80 of cigars, one of spokes, one of rope, one of carpets, one of spectacles, 10 of wool hats, 6 of cooperage, 2 distilleries, 3 paper mills, and 5

planing mills. The shops of the Philadelphia and Reading railroad employ 2,800 men. Reading contains three national banks with an aggregate capital of \$700,000, a savings bank with \$100,000 capital, and four fire insurance companies. It is divided into nine wards, and is governed by a mayor, a select council of nine members (one from each ward), and a common council of 28. There are an efficient fire department and a police force. The principal charitable associations are a dispensary and a female orphan asylum. The public schools and departments comprise 1 normal school, 1 high school, 11 grammar, 18 secondary, and 33 primary departments, and 1 colored school. The number of teachers in 1874 was 121; pupils enrolled, 6,457; average attendance, 5,326. The Reading library contains 3,000 volumes. Three daily (one German) and eight weekly (six German) newspapers, and one semi-monthly (German) periodical are published. There are 31 churches, viz.: 2 Baptist, 1 Church of God, 2 Episcopal, 3 Evangelical Association, 1 Friends', 5 Lutheran, 4 Methodist, 3 Presbyterian, 5 Reformed, 2 Roman Catholic, 1 United Brethren, 1 United Brethren in Christ, and 1 Universalist.—Reading was laid out in 1748. It was incorporated as a borough in 1783, and as a city in 1847.

READING, a borough of England, county town of Berkshire, on the Kennet, near its junction with the Thames, 39 m. W. by S. of London; pop. in 1871, 32,324. It has greatly improved within the past 20 years, and is now an important centre of railways and of trade. There are several fine churches. A working men's hall was opened in 1862, the town hall was enlarged in 1863, and the elegant station of the Great Western railway was completed in 1868. Flour and grain are largely exported to London. Silk and agricultural implements are manufactured, and there are iron foundries, breweries, and extensive biscuit bakeries.—Reading is very ancient, has returned two members to parliament since the time of Edward I., and has been the scene of important historical events.

REALTY (law Lat. *realitas*, from *res*, a thing), in law, property in lands, tenements, and hereditaments. The common law of real property is distinctively and almost entirely English, founded on the rules and customs which in the feudal period governed the tenure of lands. It is the theory of the English law that no occupant of lands, not even a freeholder, has absolute ownership of them; he has only an estate. The king is lord paramount, and all the land in the realm is holden mediately or immediately of him. The chief estates in lands of the present time originated no doubt in the various forms of feudal tenure. Life feuds were probably earlier than feuds of inheritance; for as feuds were granted in consideration of a return of military services, and as this consideration was to be furnished by a certain individual whose already known valor or fidelity

induced the gift, lands were without doubt primarily limited to the first donee; that is to say, they could neither be aliened by him to a stranger nor transmitted to his heirs. But as the lords became strong in their possessions, or when the times were more secure, it became safe and possible to grant estates of inheritance in feuds; namely, to the first taker and certain of his heirs or to his heirs in general. From these modes of tenure came the modern estates respectively, for life, in tail, and in fee. Each of these is a freehold and a real interest, but no estate less than one for life (and a lease to A for 1,000 years is, in the contemplation of the law, a smaller interest than a grant for the term of his life) is a freehold or an estate in realty. But besides lands, things real, as the tautological phrase of the law is, comprise also tenements and hereditaments; and these are embraced in this term, because they possess some of the characteristic qualities of lands, as they may be holden on tenure or are inheritable. These terms may include things incorporate. Land includes only tangible or corporeal property: the ground or soil, and everything which is attached to it naturally, as trees, stones, or herbage, or by art, as houses or other structures. Growing timber, therefore, and standing grass or grain, so long as they are rooted in and supported by the soil, are parts of the realty, though they become personalty immediately on severance. But when corn or any other annual product of the soil is ripe and fit to be gathered, though not yet severed, it is personal property. A permanent building erected on one's land becomes his property, even though the materials for it were wrongfully taken from another. But a building erected on another's land, by his permission, may remain the personal property of the builder. (See **FIXTURE**.)—Besides the incidents and elements of land which we have already mentioned, and which are examples of corporeal hereditament, there may be also incorporeal hereditaments, that is, rights annexed to and issuing out of lands, as rights of common and of way, easements, and rents. These rank next in dignity and extent to lands. (See **COMMON**, **RIGHTS OF**, **EASEMENT**, **LEASE**, and **LICENSE**.) A right of way is the right of passage over another man's ground. It may be founded in an actual grant by the owner of the soil, or may be claimed by prescription, which supposes a grant, or it may arise immediately from necessity; as where one sells a lot surrounded by other land of his, here, as a right of passage is necessary to the enjoyment of the lot granted, the grantor is conclusively presumed to have granted it to the purchaser. If the way thus granted and ordinarily used become impassable, it seems just that the purchaser shall have the right, founded on the same presumption, of passing over the adjacent lands of the grantor. Not so, however, if the way be a private one, lying in actual grant, for here the grantor presumptively bound himself to repair. The right

of the public in the highway is, ordinarily, only an easement. The fee in the soil belongs to the abutters, and the complete use of the ground returns to them whenever it becomes discharged of the easement. The road bed of railways is generally subject to the same rules. The right of soil in land bounded by navigable rivers where the tide ebbs and flows, belongs to the owner of the land as far as low-water mark. The right to navigate such waters belongs, in all states of the tide, to the public. Grants upon streams above the flow of the tide convey not only the banks but the beds of the streams and the islands in them to the middle line of the water (*ad filum medium aquæ*). But the right of the grantee is qualified by the right of the public to use the stream as a highway if it be navigable.

REAPING MACHINES. See **MOWING AND REAPING MACHINES.**

RÉAUMUR, René Antoine Ferchault de, a French natural philosopher, born in La Rochelle, Feb. 28, 1683, died Oct. 18, 1757. He studied law at Bourges, but went to Paris in 1703, gained distinction by his philosophical researches, and in 1708 was admitted to the academy of sciences. In his *L'Art de convertir le fer forgé en acier, et l'art d'adoucir le fer fondu* (1722), he first made known in France the process of manufacturing steel. For this he received a pension of 12,000 livres, which he applied to the encouragement of the industrial arts. He invented a process for tinning iron, and made experiments in the manufacture of porcelain; an opaque white glass which he made is known as "Réaumur's porcelain." He also discovered the means of preserving eggs, and made experiments in artificial incubation. In 1731 he invented the thermometer which is called after him, and is still largely used in Germany and other parts of the European continent, taking as the extremes the freezing and boiling points of water, and dividing the interval into 80 degrees. He investigated many curious topics in natural history, especially the mode of formation and growth of the scales of fishes, the development of the shells of testaceous animals, the reproduction of the claws of lobsters and crabs, and the mode of motion of star fishes and various mollusks and zoöphytes. He discovered a species of mollusk that furnishes a purple dye nearly equal to that used by the ancients. His most thorough investigations were in the department of entomology, to which he devoted several years. He published *Mémoires pour servir à l'histoire naturelle des insectes* (6 vols. 4to, 1734-42), and a variety of papers in the transactions of the academy of sciences.

REBEKAH. See **ISAAC**, and **JACOB**.

REBOLLEDO, Bernardino, count de, a Spanish author, born in Leon in 1597, died in Madrid in 1676. He served in Italy and against the Turks, took part in the thirty years' war, was created by Ferdinand II. a count of the German empire, and received the government of

the Lower Palatinate. He was several years ambassador to Denmark, and from 1662 till his death was president of the board of war at Madrid. He wrote *Ocios* ("Leisure Hours," Antwerp, 1650); *Selas militares y politicas*, poems on the arts of war and civil government (Copenhagen, 1652); *Selas dñicas* (4to, 1665), a compendium in verse of the history and geography of Denmark; and some minor writings. The best edition of his works is that of Madrid (4 vols. 8vo, 1778).

RÉCAMIER, Jeanne Françoise Julie Adelaïde, a French leader of society, born in Lyons, Dec. 4, 1777, died in Paris, May 11, 1849. Her father was M. Bernard, a banker, connected with the postal service; his receptions were attended by distinguished people, who greatly admired her extraordinary beauty, modesty, and accomplishments. In 1793 she married M. Récamier, a rich banker of middle age, for whom she felt only respect. He purchased in 1798 the hôtel Necker, which led to her lifelong intimacy with Mme. de Staël. This displeased Napoleon, and she gave him further offence by declining in 1803 to become a lady attendant on the empress Josephine. The bankruptcy of her husband made her in 1804 accept the hospitality of Mme. de Staël at Coppet, where she met Prince Augustus of Prussia. She had accepted with indifference the homage, though not the friendship, of the brothers Montmorency, Lucien Bonaparte, Benjamin Constant, and other celebrities; the only man whose affection she seems to have returned was the Prussian prince, but she refrained from urging a divorce to enable her to accept his proposal of marriage. Napoleon objecting in 1811 to her residing in Paris, she spent some years in Burgundy, Lyons, and Italy. Her patriotism remained, however, unabated, and when in 1815 the duke of Wellington paid his respects to her and exulted over Waterloo, she forbade him her house. New reverses obliged her to occupy modest apartments in the abbaye aux Bois, formerly a convent, in the faubourg St. Germain. In 1817, at the death of Mme. de Staël, she first met Chateaubriand, in whose enthusiastic admiration she took great pride. His wife dying in 1846, he offered to marry Mme. Récamier, whose husband had died in 1830; she declined, but he remained to the last her faithful friend and correspondent. (See Chateaubriand's *Mémoires d'outre tombe*.) Her partiality for royalists and for ultramontane writers of the romantic school, and the occasionally intolerant character of her brilliant receptions, did not escape criticism amid the general admiration which she inspired to the last.—See *Souvenirs et correspondance tirés des papiers de Madame Récamier*, edited by her niece and adopted daughter, Mme. Lenormant (2 vols., Paris, 3d ed., 1860; English translation by Isaphene M. Luyster, Boston, 1867), and *Madame Récamier, les amis de sa jeunesse*, by the same (1872; English translation by I. M. Luyster, Boston, 1875).

RECIFE, or **Pernambuco**, a maritime city of Brazil, capital of the province of Pernambuco, 1,150 m. N. E. of Rio de Janeiro; lat. $8^{\circ} 4' S.$, lon. $34^{\circ} 50' W.$; pop. about 100,000. It is at the common mouth of the rivers Beberibe and Capibaribe, which form a delta comprising several islands, and is divided into three quarters, Boa Vista, São Antonio, and Recife proper, united by bridges. Many of the streets are regular, particularly in Boa Vista, well paved, and lighted with gas; and the houses are partly of brick, with three and four stories. Besides handsome parish churches, there are several others, mostly attached to convents; the remaining edifices of note are the governor's and bishop's palaces, the city hall and provincial government buildings, the arsenal, custom house, lazaretto and other hospitals, and benevolent institutions. There are a lyceum, a law school, and a provincial gymnasium. The port, defended by several forts, is protected by a reef (whence the name Recife), to which masonry has been added. A breach in the reef forms the entrance to the river port, which, though very commodious, is inaccessible to craft of over 700 tons, owing to a sand bank. Recife has three banks, flourishing tobacco, soap, and paper factories, and two machine shops. The total value of the exports in the year 1872-'3 was \$12,808,788, the staples being cotton, sugar, molasses, rum, and hides. The Pernambuco and São Francisco railway extends S. E. from the city. The town is the western terminus of the submarine cable from Lisbon, completed in June, 1874. It was founded about 1530, by Duarte Coelho, and erected into a bishopric in 1676. The English occupied it in 1595; it was seized by the Dutch in 1629; and it has repeatedly been the scene of insurrections, particularly in 1661 and 1710.

RECITATIVE (Lat. *recitare*, to recite; called by the Italians *musica parlante*, speaking music), a species of artificial declamation adapted to musical notes, imitating the inflections of natural speech, and forming a medium between ordinary recitation or speaking, which it nearly resembles, and measured air or song. It was first introduced at Rome by Emilio del Cavaliere in 1600, and is now a recognized and indeed an essential form of vocal composition in the grand Italian opera, oratorios, and cantatas, serving to express some action or passion, to relate a story, or to connect scenes and situations, without injuring the effect of the performance by resorting to spoken words. Although written in common time, the recitative may be delivered by the singer according to his fancy, subject of course to the laws of prosody, the lengths of the notes as given by the composer being mere approximations. The accompaniment generally consists of a few occasional chords struck by the pianoforte to indicate the harmony, although sometimes the violoncellos take the chords in *arpeggio*. This, the simplest form of recitative, is called *reci-*

tativo secco; when besides the bass the recitative is accompanied by other instruments of the orchestra, it is *recitativo instrumentato*; when interrupted by interjected passages performed by the orchestra, it is said to be *obbligato*. The more modern composers have given great attention to elaborating the recitative, Wagner having gone so far as to banish the *aria* and substitute in its place a kind of musical recitation, between recitative and song.

RECLUS, Jean Jacques Elisée, a French geographer, born at Ste. Foy la Grande, department of Gironde, March 15, 1830. He studied under Carl Ritter in Berlin, and travelled in Great Britain and North and South America from 1851 to 1857, when he returned to France and published a series of books of travel. For continuing to serve in the national guard of Paris after the establishment of the commune he was sentenced to death (1871); but the sentence was commuted to banishment, and he was finally pardoned. His principal works are: *La terre* (2 vols., 1867-'8; English translation, "The Earth," edited by B. B. Woodward, 2 vols., New York, 1871); *Les phénomènes terrestres, les mers et les météores* (1872; English translation, "The Ocean, Atmosphere, and Life," by B. B. Woodward, edited by Henry Woodward, New York, 1872); *Voyage aux régions minières de la Transylvanie occidentale* (1873); and *Nouvelle géographie universelle* (part i., 1875).

RECOGNIZANCE (law Fr. *reconnaissance*; law Lat. *recognitio*), an obligation of record entered into before a court of record or magistrate duly authorized to take it, with condition to perform some specified act; as to appear at the assizes or criminal court, to keep the peace, to pay a debt, or some other thing of a like description, upon the performance of which condition the obligation is to become null and void. The state or person in whose favor or to whom the recognizance is made is called the cognizee, and the person who enters into it the cognizor. The word recognizance is given to this kind of obligation, because, generally, the form of it is this: the clerk or other proper officer says to the cognizor: "You acknowledge yourself bound to," &c.; to which the cognizor assents; and it is then made matter of record.—Recognizances are of several kinds and descriptions, and are used for various purposes both civil and criminal. Of the former kind was a recognizance of debt at common law, in the nature of a deed to charge or encumber lands. This was very similar in form and effect to an ordinary bond, the main distinction being that while a bond is the creation of a fresh debt or obligation, a recognizance was the acknowledgment of a debt already existing upon record. It was certified to or taken by the officer of some court, and witnessed only by the record of such court, instead of having the cognizor's seal affixed to it. It was not strictly a deed, though in effect it was of greater force and obligation, and was

allowed a priority of payment, and bound the lands of the cognizor from the time of its enrolment on record. It operated as a lien upon all the lands which the cognizor possessed at the time he acknowledged it, and also upon all those which he afterward acquired, so that no alienation of them made by him while his recognizance remained in force would defeat the claim of the cognizee or prevent his extending such lands. Recognizances for debt may still be taken in this country under statutory provisions, but they operate merely as evidences of debt in the nature of a judgment, upon which execution may issue, and do not generally create a lien upon the cognizor's land or other property.—There were also, at common law, two other recognizances of a private sort, said to be in the nature of a statute staple and a statute merchant. The undertaking of special bail in a civil action, of which the bail piece (a slip of parchment so called, on which it was transmitted to court) was a memorandum, was a recognizance entered into by the cognizors before the court or judge for a sum equal (or in some cases double) to that which the plaintiff had sworn to, by which they undertook that if the defendant was condemned in the action he should pay the costs and condemnation, or render himself a prisoner, or that they would pay it for him.—In criminal practice recognizances are used both as a means of securing the proper administration of justice by compelling the appearance of a party accused before a magistrate for further examination, or for trial at some superior court, and of securing the attendance of witnesses by binding them, with sufficient sureties, to appear and testify. They are used also as a means of preventing the commission of crimes, by obliging the persons suspected of an intent to commit them to recognize in some penal sum, with pledges or sureties, to keep the peace and be of good behavior for a certain time. A recognizance to keep the peace may be taken by any justice of the peace, from any one who creates an affray or disturbance in his presence, or goes about with unusual attendance or weapons to the terror of the people, or is brought before him by a constable for a breach of the peace; and he is bound to grant it in favor of any person who can show just cause to believe that he is in danger of bodily harm at the hands of another. A recognizance for this purpose is an obligation in the nature of a bond with one or more sureties, entered of record, with condition that if its requirements are fulfilled and the cognizor keeps the peace for the time therein specified, it shall be void and of no effect. If on the contrary it is broken by any breach of the peace, it becomes forfeited or an absolute debt, and the cognizor and his sureties may be sued for the sums in which they are respectively bound. If it is a special recognizance, as to keep the peace toward any particular person, it may be forfeited by any actual violence, or

even an assault or menace, to such person, and to such person only. If it is a general recognizance, it is forfeited by any act which tends to break the peace, done to any person or thing in general.—A recognizance may be discharged by the death of the principal party bound thereby, or by the order of the court to which it is certified by the justice, if they see sufficient cause. If granted upon private account, it may be discharged if the person at whose request it was granted will consent to release it, or does not make his appearance to pray that it may be continued.—At the common law a peer or peeress could not be bound to recognize in any other place than the court of king's bench or chancery; but a justice of the peace had power to require sureties from any person, not a lunatic and under the degree of nobility, whether such person were a fellow justice or other magistrate or merely a private man. Wives may demand it against their husbands, and husbands, if necessary, against their wives; but at common law married women and infants should find security by their friends, because they are incapable of engaging themselves to answer any debt. Some exceptions are made by statute, and the sweeping enlargement of the legal capacities of married women by the legislation of some states has probably removed this disability.—In old practice the verdict of an assize, or strictly the act of the jury in inquiring into the case in order to make up their verdict, was called a recognizance.

RECOLLECTS. See FRANCISCANS.

RECORD (Lat. *recordari*, Fr. *recorder*, to remember). **1.** An official contemporaneous memorandum in writing, drawn up by the proper officer of a court of justice, and containing a summary statement of the proceedings in an action at law brought before that court. This statement comprises a short history of the case and the proceedings consequent thereon; as the nature of the action, the names of the parties and the time of their appearance in court, and the acts of the court itself during the progress of the pleadings, arranged in the order of their occurrence, and sometimes connected by peculiar entries called continuances, the whole concluding with the judgment of the court with respect to the question at issue. These continuances were adjournments of the case from one day or term to another, which the law allowed for certain purposes, and which were entered with the pleadings and other proceedings on the roll or record, and gave the whole a complete and connected form. These records were always written upon rolls of parchment, which indeed was an essential characteristic of a record. In the United States paper is universally used as a substitute for parchment, and the roll form has consequently been abolished, but otherwise the forms of the English records have been generally adopted. Records in this technical sense are peculiar to the common law; and as they form the only strict and proper proof of the pro-

ceedings of the courts in which they are preserved, they are regarded with particular consideration, and are generally a proof of such a high and absolute nature as to admit of no contradiction. In Sir Edward Coke's words, they "import in themselves such uncontrollable credit and verity, as they admit of no averment, plea, or proof to the contrary." The existence of a record can only be tried by itself; that is, if in any action the existence of any matter on record is alleged, and the adverse party pleads *nul tiel record*, or that there is no such record, the issue arising thereon is determined merely by the inspection of the record itself by the court, without witnesses or jury, because no issue can be joined upon it to be tried by a jury as upon matters of fact; and the record is conclusive proof without further evidence. The peculiar privilege of some courts to have these memorials has of itself created the great leading distinction, equally recognized in English and American law, between courts of record and courts not of record. Though courts not of record may keep minutes or memorials of their proceedings, such minutes are not properly records. Legally, the term records applies to the rolls of such only as are courts of record, and not to the rolls of inferior or any other courts which proceed not *secundum legem et consuetudinem Angliæ*, or according to the laws and customs of England. During that term of the court in which any judicial act is to be done, or before the case pending is concluded, the record is said to remain in the breast of the judges of the court, and in their remembrance, and therefore it may be altered during that term in such manner as the judges shall direct. But as soon as that term is ended the record is closed, and it is then said to admit of no change, alteration, or proof to the contrary. But some courts claim and exercise the right to make amendments therein whenever the record is found not to conform to the facts.—The practice of recording is said to be of Norman origin. It existed in the French law, generally, as early as the time of the conquest, if not earlier, and in the same form as that which it bore in Normandy. In the *Assises de Jérusalem*, which was a code of feudal jurisprudence compiled as early as 1099, and intended for the kingdom of Jerusalem then newly established, litigants were directed to collect as many of their own friends as possible in court, and request them to attend to what was said, so that they might retain and record it properly at the time of judgment or trial. They were further directed, if there should be an adjournment or further day appointed for the hearing, that both plaintiff and defendant should put down in writing the nature of the claim and other particulars, in order that they might testify to them at the adjourned meeting if necessary, and thereby assist or confirm the recollection of the judges. This practice finally became developed, from the mere private memoranda of the pleaders, into an official

contemporaneous minute of the proceedings. "Whether this change," says Mr. Stephens, "had fully taken place at the date of Glanvil's treatise (in the reign of Henry II.), that work does not enable us accurately to decide. However, we find, at least very shortly after that period, the practice of recording, in the present sense of the term, was in full operation." Next to Domesday Book, which, though not a legislative record, has all the validity of one, is the "Exchequer Register" (Pipe Roll) of 31 Henry I. The series of legal records in the court of king's bench, now extant, reach from the reign of Richard I. to the present day. The peculiar construction of the record, showing as it did every proceeding in the action precisely as it took place, gave it at a very early period the highest authority as a judicial memorial; and its importance in this particular led to a suitable degree of care in framing and preserving it. Its language gradually reached the highest degree of precision and uniformity, and the whole instrument settled at last into a fixed form of expression, which neither admitted of nor required any variation. When written pleadings took the place of oral, they were framed in the same manner as they had previously appeared on the record, and were in fact simply extracts from it, the same concise and technical forms of expression being always used. From this arose a leading principle of practice, viz., that every proceeding in an action intended or required to appear on the record, must be framed in the language of the record, and with the same exactness as the record itself. Two other circumstances united to give the record the unchangeable character which has accompanied it down to modern times, and almost to the present day. One was, that it was kept in Latin, a language which admitted of no variation; and the other was its inviolable character, which preserved it from the slightest alteration after being once made up. The substitution of the English for the Latin language, and of ordinary writing for the "ancient and immutable court hand," took place in the reign of George II., and was considered by competent judges of that time as a dangerous innovation. It has been certainly followed by other important alterations and modifications, which have greatly impaired the original character of the record as a complete and immutable memorial of all the proceedings in an action. The old continuances and the formal commencements and conclusions of the pleadings are now omitted, the language of the pleadings themselves is greatly modified, and the present tendency undoubtedly is to deprive the record in a great measure of the high dignity and importance which it anciently possessed. II. Record, as the title, or rather evidence of title to real estate, by the record or register of title deeds, is of American origin. The usage has prevailed from the early settlement of New England, and is now universal throughout the United States. By the laws of Massachusetts in 1641

all deeds of conveyance, whether absolute or conditional, were required to be recorded, that "neither creditors might be defrauded nor courts troubled with vexatious suits and endless contentions." The statutes of the various states differ in some immaterial respects as to the time and manner of registry, and as to what deeds or instruments must be recorded; but the principle in all is the same, and all make such record absolutely necessary in order to complete the purchaser's title, and render it valid against creditors and subsequent *bona fide* purchasers. If the deed is not recorded, the sale is nevertheless good and the title passes as between the immediate parties and their heirs and devisees, but it is void as against subsequent *bona fide* purchasers and mortgagees whose deeds are first recorded. In some of the states a specified time is allowed in which the deed may be recorded, but in general the grantee is left to put his conveyance on record whenever he sees fit, the risk of delay being that his title may be lost by another conveyance from his grantor to a *bona fide* purchaser. In 1880 the real property commissioners in England recommended the establishment in that country of a general registry of deeds and instruments relating to land, as contributing to the security of title and the cheapness and facility of transfers of land, and in 1862 such a registry was provided for; but hitherto it has not come into general use. Heritable but not leasehold property is recorded in Scotland in a public register, and the deed must be recorded within 60 days to render it valid against creditors and purchasers. A very simple system for the registration of land titles prevails in Australia, corresponding to the registration of vessels.—It has sometimes been a question whether notice of the transfer of property to a subsequent purchaser was equivalent to a record of the prior deed, and whether the deed of a subsequent purchaser with such notice, duly recorded, would be valid against the prior unrecorded conveyance. The record of a title deed is not considered as conferring title in itself, but merely as evidence of notice or as constructive notice to the public of the title passed by the deed of conveyance of which it is an official and certified copy; and it is therefore a general rule that notice, actual or implied, to a subsequent purchaser of a prior conveyance, is as effectual to defeat his claim as a *bona fide* purchaser as a due record of such conveyance would be; for so long as he receives notice of the prior encumbrance, it makes no difference whether such notice is derived from a record or from any other authentic source, and he purchases thereafter at his peril. In other words, if he knows that the land he buys has already been conveyed to another person who has neglected to record the deed, he cannot claim the rights of a *bona fide* purchaser.

RECORDE, Robert, an English mathematician, born at Tenby, Pembrokeshire, about 1500,

died in London in 1558. He entered Oxford university in 1525, was elected a fellow of All Souls' college in 1531, and taught rhetoric, mathematics, music, and anatomy. In 1545 he received the degree of M. D. from Cambridge university, removed to London, and was physician to Edward VI. and to Queen Mary. He died a prisoner in the king's bench, probably for debt, though he left some property. He wrote the "Gate of Knowledge" and the "Treasury of Knowledge," both of which are lost. His extant works are: "The Ground of Artes, teaching the Woorke and Practice of Arithmetike" (1540), his most popular work; "The Vrial of Physick" (1548); "The Pathway to Knowledge" (1551), a compendium of geometry; "The Castle of Knowledge" (1556); and "The Whetstone of Witte," a mathematical work (1557).

RECORDER, an obsolete wind instrument, resembling the flageolet, though by some writers it has been confounded with the flute. It is said to have had six vents. Its tone was soft and pleasing, whence Milton speaks of "flutes and soft recorders."

RECUSANT (Lat. *recusare*, to refuse), a term of frequent occurrence in English ecclesiastical history, and used to designate those persons in general who refused or neglected to attend divine service on Sundays or holidays in the established church, or to worship God according to its forms. The use of the word to designate a legal offence is traced to the first year of Queen Elizabeth, when it was enacted that all persons who, without reasonable excuse, failed to attend some usual place of prayer, should be censured and fined for every omission 12 pence. In 23 Elizabeth the fine or forfeiture was made for every month 20 pounds; and in 35 Elizabeth it was enacted that if recusants failed to submit within three months after conviction, they might, upon the requisition of four justices of the peace, be compelled to abjure and renounce the realm; and if they did not depart, or if they returned without license of the crown, they were guilty of felony and should suffer death without benefit of clergy. In the case of recusants who professed the Roman Catholic religion, and who were designated popish recusants, the laws were more severe; in addition to the above general penalties, they were disabled from taking lands, either by descent or purchase, after the age of 18, until they renounced their errors, and were incapacitated in several minor rights of the subject. "Popish recusants convict," as they were called after being convicted, were virtually outlaws. Protestant dissenters were relieved from the penalties of recusancy at the revolution by the toleration act. This statute contained a proviso depriving of its benefit any papist or popish recusant, or any person who should deny the doctrine of the Trinity; but Roman Catholics were exempted from prosecution by 31 George III. in 1791, and more fully by the Catholic emancipation act of

1829. In 1813, by 53 George III., relief was extended to those who denied the doctrine of the Trinity; but the statutes against recusancy still exist, though they are seldom enforced, against persons who absent themselves from church, being neither Roman Catholics nor Protestant dissenters.

RED BIRD. See **CARDINAL BIRD**.

REDBREAST. See **ROBIN**.

REDDING, Cyrus, an English journalist and author, born in Penryn, Cornwall, in 1785, died in London, May 28, 1870. He went to London in 1806, was engaged upon the staff of "The Pilot," and established and conducted the "Plymouth Chronicle." From 1815 to 1818 he resided in France, where he edited "Galignani's Messenger." He was editor of the "New Monthly Magazine" from 1820 to 1830, jointly with the poet Campbell, with whom in the latter year he began the "Metropolitan," which proved unsuccessful. Subsequently he edited for two years the "Bath Guardian," and in 1836 established the "Staffordshire Examiner," both liberal in politics. He returned to London in 1840. His works include a collection of poems published under the title of "Gabrielle" (1829); "History and Description of Modern Wines" (1833), which has been many times republished; "Fifty Years' Recollections, Literary and Personal" (3 vols., 1858); "Keeping up Appearances," a novel (1860); "French Wines and Vineyards, and the Way to Find them" (1860); "Literary Reminiscences and Memoirs of Thomas Campbell" (2 vols., 1860), originally contributed to the "New Monthly" soon after the poet's death; "All's Well that Ends Well" (1862); "Memoirs of Remarkable Misers" (2 vols., 1863); "Yesterday and To-day" (1863); and "Past Celebrities whom I have Known" (2 vols., 1865).

REDEMPTION, Equity of. See **MORTGAGE**.

REDEMPTORISTS, or Congregation of the Most Holy Redeemer, known also as Liguorians, a society of missionary priests in the Roman Catholic church, founded by St. Alfonso Maria da Liguori. The foundation of the society dates from Nov. 9, 1732, when Alfonso, with twelve priests, two candidates for orders, and a rich gentleman who volunteered to serve them as lay brother, united in community at Scala, in the Neapolitan province of Benevento. After laboring together successfully for some time, Alfonso deliberated with his companions on the choice of a rule of life; but the diversity of opinions among them became irreconcilable, and they dispersed, one priest and the lay brother, Vito Curzio, remaining with Alfonso. As Alfonso continued his labors, new members flocked to him, several houses were established, and the rules drawn up by him for the government of the society were approved in 1749 by Pope Benedict XIV., Alfonso himself being chosen superior general for life.

The rule of the Redemptorists prescribes, besides the three usual monastic vows, a fourth, which obliges the members to accept outside of the order no dignity, office, or benefice, except upon an express order of the pope or the superior general, and not to leave the order unless by special permission of the pope. The principal sphere of action of this order has been the conducting of what is called a "mission," lasting one, two, or more weeks, during which time the missionaries endeavor to prevail upon all the members of a church to devote their time principally to religious exercises and a thorough reformation of their lives. St. Alfonso and his companions followed in this the method of the Jesuit missionaries in Italy. When the Jesuits were suppressed by Clement XIV., Alfonso aimed at replacing them by his order as popular instructors. This circumstance, and Alfonso's known love for the suppressed order, caused the Redemptorists to be not unfrequently confounded with the Jesuits. The order spread early from Naples into Sicily and the Papal States; but even before the death of the founder all the houses in the kingdom of Naples were excluded from the order, because they had procured a ratification from the government at the expense of important and unauthorized alterations of their rule. The division lasted till 1790, when a reunion was effected. The first German members established missions in Courland and at Warsaw, but both succumbed to the wars arising out of the French revolution. In Austria they have had since 1808 many influential patrons, and it has ever since remained one of the most important provinces of the order. In France they suffered some losses from the interference of the government in 1830, and again in 1861. They have found an important sphere of action in the United States, whither they first came in 1841, and where they principally labor among the German population. In 1858 a number of American Redemptorists left the order and established with the pope's sanction an independent missionary congregation. (See **PAULISTS**.) In 1874 they were called to Canada and placed in charge of St. Patrick's church, Quebec. In 1870 the Redemptorists were involved with the Jesuits in the decree of the Italian parliament suppressing all religious orders in Italy; in 1873 their central residence in Rome was also suppressed. In the latter year the German parliament decreed their expulsion from Germany, and on May 31, 1875, another decree sequestered their property and deprived them of all civil rights in Prussia. A similar proscription swept away their houses in Switzerland and banished their members. In France, where they possessed eleven houses in 1869, their numbers have not increased since the war, the French government refusing the Redemptorists exiled from Germany permission to settle there. These have taken refuge principally in the British empire and colonies, and in the United States. In this country

they have (1875) houses in Maryland, Massachusetts, Louisiana, Mississippi, and Illinois.—A congregation of Redemptorist nuns, which was likewise founded by Liguori in 1732, has never extended itself widely.

REDFIELD, Isaac Fletcher, an American jurist, born in Weathersfield, Vt., April 10, 1804, died in Boston in March, 1876. He graduated at Dartmouth college in 1825, studied law, and practised at Derby and afterward at Windsor, Vt. From 1835 to 1860 he was a judge of the supreme court, being chief justice from 1852; and from 1858 to 1862 he was professor of medical jurisprudence in Dartmouth college. In 1861 he removed to Boston. From January, 1867, he was for two years special counsel of the United States in Europe, having charge of many important suits and legal matters in England and France. He received the degree of LL. D. from Trinity college in 1848, and from Dartmouth in 1855. He published "The Law of Railways" (1857; 5th ed., 2 vols., 1873); "The Law of Wills" (3 vols., 1864); "The Law of Carriers and Bailments" (1869); "Leading American Railway Cases" (2 vols., 1870); and with W. A. Herrick, "A Treatise on Civil Pleading and Practice" (1868). From 1862 he was one of the editors of the "American Law Register" (Philadelphia); and he also edited Story "On Equity Pleadings" and "Conflict of Laws," and Greenleaf "On Evidence," and contributed very largely to periodicals.

REDFIELD, William C., an American meteorologist, born in Middletown, Conn., March 26, 1789, died in New York, Feb. 12, 1857. In early life he was a mechanic. In some pedestrian journeys he observed the course of the hurricane in September, 1821, long known as the "great September gale," and became convinced that the storm, instead of moving in a straight line, according to what was then supposed to be the law of such storms, had rotated around a central point, and that its movement had been in curved lines. Having established a line of steam tow boats on the Hudson, and taken up his residence in New York, he investigated the connection of steam with navigation, and in pamphlets, essays, and published letters discussed the causes of steamboat explosions, the means of safety, and the necessity of careful and frequent inspection. In 1828 he published a pamphlet urging the importance of a system of railways to connect the waters of the Hudson with those of the Mississippi; and he was largely engaged in promoting railroad construction. In 1831 he first gave to the public his "Theory of Storms," and three years later an elaborate article on the hurricanes of the West Indies. After 1836 he devoted much time to the investigation of the fossil fish of the Connecticut valley and the sandstones of the Atlantic coast in New Jersey, Virginia, and North Carolina, and made a very large collection of them; and he read before the American association for the ad-

vancement of science several papers on those fossils. He published during his life 62 essays, of which 40 pertain to meteorology; the best known are accounts of hurricanes. (See HURRICANE, and METEOROLOGY.)

RED FIN. See DAOE.

REDGRAVE, Richard, an English painter, born in London, April 30, 1804. He studied at the royal academy, and in 1837 exhibited his first successful work, representing "Gulliver on the Farmer's Table." His subsequent genre pictures delineate the sufferings of the poor, and at a later period he painted landscapes. His most celebrated pieces are "Country Cousins," "Cinderella," "Ophelia," "The Governess," and "Bolton Abbey." He was elected to the royal academy in 1857, and holds (1875) the offices of inspector general of art schools, for which he has prepared a system and course of instruction, and surveyor of crown pictures. He has published "An Elementary Manual of Colors" (London, 1863), and in conjunction with his brother, Samuel Redgrave, "A Century of Painters of the English School" (1866). The latter has also published "A Dictionary of Artists of the English School" (1874).

REDI, Francesco, an Italian naturalist, born in Arezzo, Feb. 18, 1626, died in Pisa, March 1, 1698. He was physician to successive grand dukes at Florence, and acquired a high reputation in his profession, and also as a naturalist, classical scholar, and poet. He belonged to the school of Galileo, and his writings are alike distinguished for depth of scientific inquiry and philosophic acumen. He first clearly enunciated the doctrine that all living organisms must have originally sprung from preëxisting germs, and contended that in all cases of the apparent production of organized beings from dead matter, as in putrefactions and animal and vegetable infusions, the previous existence or subsequent introduction of such germs must be presumed. He openly attacked the doctrines of the abiogenists, or defenders of the theory of spontaneous generation, opposing their assertions by a series of simple and for the time almost conclusive experiments, which still serve modern naturalists as a basis in similar researches. (See SPONTANEOUS GENERATION.) His most important works are *Osservazioni intorno alle vipere* (4to, Florence, 1664; Latin translation, Amsterdam, 1678); *Esperienze intorno alla generazione degli insetti* (1668; Latin, 1671), which had many editions; and *Osservazioni agli animali viventi che si trovano negli animali viventi* (1684). The finest of his poems is *Bacco in Toscana* (1685), a eulogy of the wines of Tuscany. He also wrote lives of Dante and Petrarch. The latest edition of his complete works was published at Milan in 1809, in 9 vols. 8vo.

RED JACKET (SA-GO-YE-WAT-HA), a principal chief of the Senecas, of the Wolf tribe, born at Old Castle, near the foot of Seneca lake, in 1752, died at Seneca Village, near Buffalo, N. Y., Jan. 20, 1830. His original In-

dian name was O-te-ti-ani, "Always Ready," that of Sa-go-ye-wat-ha, "He keeps them awake," having been conferred upon him on his election to the dignity of a sachem. The name of Red Jacket arose from a richly embroidered scarlet jacket presented to him by a British officer, which he always took great pride in wearing. Of his early history little is known except that he was remarkably swift in the chase, and was often employed as a messenger, first among his own people, and during the revolution as a runner for the British officers on the border. In 1784, in a council held at Fort Stanwix to negotiate between the United States and the Six Nations for the cession of lands, he spoke very eloquently against the treaty, but with no avail. A few years later Red Jacket had an interview with Washington, who gave him a silver medal. In 1809 he gave information to Erastus Granger, the Indian agent, of the organization by Tecumseh of an extensive league by which the Senecas were to be drawn into a combination against the United States. In 1810 he visited Washington, and delivered an able speech upon this subject before the secretary of war. In the war of 1812 he on several occasions gave advice which proved of essential service to the American army, especially on the eve of the battle of Chippewa. In 1829 Red Jacket visited New York on his way to Washington, and while there sat for his portrait to Robert W. Weir. Although in his 77th year, he was still strong and vigorous. In his later years he was grossly intemperate, but invariably abstained from fire water for a season before a council. Red Jacket was upon the war path during both conflicts between the United States and Great Britain, in the first on the British and in the second on the American side; but in neither did he win the right to wear the eagle plume. His character was marked by striking contradictions. He lacked firmness of nerve, but possessed unbending firmness of purpose and great moral courage. His intellectual powers were of a very high order. He was a statesman of sagacity, and an orator of surpassing eloquence, yet capable of practising the lowest cunning; but he was still a patriot, and loved his nation and his race. His life has been written by W. L. Stone (8vo, Albany, 1867).

REDOUTÉ, Pierre Joseph, a French painter of flowers, born at St. Hubert, near Liège, July 10, 1759, died in Paris, June 19, 1840. He belonged to a family of painters, and, having settled in Paris, painted some of the most elegant flowers in the series known as the *collection des velins*, commenced under Louis XIV. In 1822 he became professor of vegetable iconography at the *jardin des plantes*. His magnificent works, *Les Uliacées* (8 vols. fol., Paris, 1803-'16), and *Les roses* (3 vols. fol., 1817-'24), are the finest known specimens of botanical illustration. A copy of the former on vellum, with the original drawings, was purchased by the empress Josephine for

84,000 francs. He invented a method of painting in colors, for which he received a medal from the society for the encouragement of national industry.

REDPOLL. See LINNET.

RED RIVER, a tributary of the Mississippi, and the last of considerable size which it receives. It rises in N. W. Texas, in about lat. 34° 40' N. and lon. 102° 10' W., and flows E. to the 100th meridian. Thence it follows a direction a little S. of E., separating Texas from Indian territory and Arkansas, and entering the latter state, bends at Fulton to the south, passes into Louisiana, and afterward flows S. E., entering the Mississippi 341 m. above its mouth. Its length is about 1,200 m., and its basin is about 97,000 sq. m. in extent. Its sources are in the fissures of an elevated and barren plain, the Llano Estacado, 2,450 ft. above the sea. For about 60 m. the banks rise perpendicularly from 500 to 800 ft. After leaving the Llano Estacado it flows over a broad bed of light shifting sands through an arid prairie country to the "cross timbers," a belt of woodland between the 98th and 97th meridians. Below this the river flows through rich and densely wooded alluvial bottoms. "Here the borders contract, and the water for a great portion of the year washes both banks, carrying the loose alluvium from one side and depositing it on the other, in such a manner as to produce constant changes in the channel, and to render navigation difficult. This character continues throughout the rest of its course; and in this section it is subject to heavy inundations, which often flood the bottoms to such a degree as to destroy the crops, and occasionally leave a deposit of white sand, rendering the soil barren and worthless." From its source to Fulton, Ark., about 600 m., the stream falls 2,208 ft.; thence to its mouth, 595 m., the fall is only 188 ft. The width between the banks 8 m. below the point where it issues from the Llano Estacado is 2,700 ft.; just below the mouth of the North fork, 2,000; 50 m. lower down, 2,100; at the mouth of the Big Wichita, 600; at Alexandria, La., 720; at the mouth of the Black river, 785; and at the entrance into the Mississippi, 1,800. "The depth varies inversely as the width, being only 6 or 8 ft., even in floods, throughout the desert, while it is some 50 ft. in the fertile region. In extreme low water a depth of 3 ft. may be depended upon below Alexandria, about 4 ft. thence to the head of the raft, and 1 ft. thence to Fort Towson (Indian territory). Steamers of 4 ft. draught can ascend to Shreveport, La. (330 m. above its mouth), at any time except in extreme low water, but to Fort Towson or even Fulton for only about three months in the year, and frequently only run in one direction during a single rise." The river is generally highest from December to June or July, the rest of the year being the season of low water. The raft has been a

serious obstacle to navigation, as it required the boats to leave the channel and pass through lakes and bayous. The "great raft," an immense collection of trees and drift wood, extended from near Grand Ecore to a little below Shreveport when the United States first undertook its removal. Capt. Shreve opened a navigable channel through it in 1835-'9. Meanwhile, from continued accessions of drift timber, the head of the raft was carried above Shreveport to near Hurricane bluff. This portion was opened by Gen. Williamson and Capt. Linnard from 1841 to 1845. In 1871 the foot of the raft was at Carolina bluff, a few miles above Hurricane bluff, and its head near Springbank, about 45 m. above its foot. Operations were begun on this raft, under the direction of Lieut. Woodruff, on Dec. 1, 1872, which resulted in opening a navigable channel through its whole length in November, 1873. At a small annual expense for a few years the renewal of the raft may be prevented, and an excellent cotton region between Shreveport and Fulton developed. Red river receives its name from its peculiar color, supposed to be derived from the red clay of the gypseous formation through which its upper course lies. The chief tributaries on the left bank are the North fork (a little W. of the 99th meridian) and the Washita, in Indian territory; Little river, in Arkansas; and Black river, formed by the Washita and Tensas, which enters in Louisiana not far from the Mississippi. On the right bank the chief tributaries are the Pease and Big Wichita rivers, which enter from W. Texas. In Louisiana Red river sends off numerous bayous, which find their way back again to the main stream, forming frequent lakes. —In the spring of 1864 an immense expedition of combined land and naval forces, the former under Gen. Banks and the latter under Admiral Porter, was sent up the Red river to capture Shreveport and thus open up the great cotton districts of Texas. It was unsuccessful, Banks's defeat at Sabine Cross Roads by Gen. Kirby Smith (April 8) compelling also the retreat of the fleet down the river. This was effected with great difficulty and loss, the river being very low and still falling, and the gunboats and transports exposed to the fire of the confederate forces from the banks. On reaching the falls, near Alexandria, further progress would have been impossible but for the bold conception and construction of a dam by Lieut. Col. Bailey of Wisconsin. (See ALEXANDRIA, La.) The main dam still remains intact, and the river has formed a new channel on the W. shore.

RED RIVER. I. A N. parish of Louisiana, intersected by Red river, and bounded E. by Black river; area, 325 sq. m. It has been formed since the census of 1870. The surface is level, and the soil fertile and productive of cotton and corn. Capital, Coushatta Chute. II. A N. E. county of Texas, separated from the Indian territory by Red river, and bounded S. by Sulphur river, one of its branches;

area, 872 sq. m.; pop. in 1870, 10,653, of whom 4,148 were colored. It has an undulating surface and fertile soil. The chief productions in 1870 were 385,840 bushels of Indian corn, 13,444 of oats, and 3,069 lbs. of wool. There were 2,522 horses, 1,242 mules and asses, 3,813 milch cows, 868 working oxen, 9,547 other cattle, 1,739 sheep, and 20,131 swine. Capital, Clarksville.

RED RIVER OF THE NORTH, a stream rising in Elbow lake, 1,680 ft. above the sea, on the border of Becker and Beltrami counties, Minnesota, in about lat. 47° 10' N. and lon. 95° 25' W. It flows S. for about 100 m. through several small lakes to Otter Tail lake in the county of the same name, and thence W. 100 m. to Breckinridge, Wilkin co. (lat. 46° 15', lon. 96° 35'), whence it runs N. about 550 m., separating Dakota from Minnesota and dividing Manitoba into two unequal parts, and empties into the S. extremity of Lake Winnipeg (628 ft. above the sea) through six mouths, amid extensive marshes, about lat. 50° 30' and lon. 96° 50'. It is very tortuous, its length being about twice that of straight lines following its three principal directions. The portion between Breckinridge and Otter Tail lake is also called Otter Tail river, the term Red river being sometimes restricted to the portion below Breckinridge. It is sluggish, except at the rapids or chutes, flowing through a very flat prairie, between clay banks varying from 20 to 60 ft. in height. The area within the United States drained by it is about 32,000 sq. m., in which the annual rainfall is comparatively small. The water is muddy but agreeable to the taste. The river is subject to annual spring freshets, very variable in duration and height, which are due to ice gorges. Its valley is but thinly settled. The principal towns along its banks, all of which are small, are Breckinridge, McCauleyville, and Moorhead in Minnesota, Fargo and Pembina in Dakota, and Winnipeg or Fort Garry in Manitoba. Between Moorhead and Fargo, 50 m. N. of Breckinridge, the Northern Pacific railroad crosses it. The business on the river consists principally in carrying supplies for the settlements in Manitoba and bringing back furs. Two or three small steamers ply in summer between Moorhead and Fort Garry, and a considerable amount of freight is floated down in flats. At Breckinridge the Red river receives the Bois de Sioux or Sioux Wood river, flowing N. from Lake Traverse. The chief tributaries from the west are the Wild Rice, Cheyenne, Elm, Goose, Turtle, Big Salt, Little Salt, and Pembina rivers in Dakota, and the Scratching and Assiniboin rivers in Manitoba, the latter being its largest affluent. From the east the principal tributaries are the Buffalo, Sand Hill, Red Lake, Snake Hill, and Two rivers in Minnesota, and the Roseau or Reedgrass river and the rivière Seine in Manitoba. These streams drain an immense number of small lakes.

RED SEA, an inlet of the Indian ocean, extending from the straits of Bab-el-Mandeb, lat. $12^{\circ} 40'$ N., nearly N. N. W. to Suez, lat. $29^{\circ} 57' 30''$, and separating Arabia on the east from Egypt, Nubia, and Abyssinia on the west. Its length is about 1,400 m., its greatest breadth, near lat. 16° , 200 m., and its total area about 185,000 sq. m. At the straits of Bab-el-Mandeb, by which it is joined to the Indian ocean, it is but 18 m. wide, at Hodeida about 95 m., and at Jiddah about 120 m. At Ras Mohammed, lat. $27^{\circ} 45'$, it is divided into two branches by the rocky peninsula of Mt. Sinai or Jebel Musa. The western branch, the gulf of Suez, which is the continuation proper of the Red sea, is about 180 m. long, and has an average breadth of 20 m. It has the same general course as the main part of the sea, with which it is connected by the strait of Jubal. At its N. extremity the Suez canal connects it with the Mediterranean, from which it is separated by the isthmus of Suez. The eastern branch, the gulf of Akabah, extends N. N. E. from its mouth at the strait of Tiran, about 100 m., and has an average breadth of about 12 m. The Red sea varies greatly in depth. In the middle of the gulf of Suez it is from 250 to 300 ft. deep, but shoals gradually to 18 or 20 ft. in the harbor of Suez, where it has been filled up by the sand. The gulf of Akabah varies from 700 to 1,500 ft. in depth. The deepest sounding obtained is in the Red sea proper, in lat. $22^{\circ} 30'$, where the depth is 6,324 ft. In the S. part it is shallower, and below lat. 16° its depth ranges from 250 to 750 ft. A section through the middle of the sea from the straits of Bab-el-Mandeb to Suez represents a series of rounded submarine hills, covered with silt, mud, and sand. The sand, which is blown in from the neighboring deserts, constitutes the only distinctive feature between this ooze and that of the bottom of the Atlantic. Near the shores on both sides the water is generally shallow, and navigation is rendered dangerous by many rocky islands, shoals, and coral reefs. The principal islands are the Farsan group on the Arabian coast, about lat. 17° , and the Dahlac group on the W. side, in lat. 16° , each consisting of large islands surrounded by many smaller ones connected by reefs. In lat. $15^{\circ} 40'$ is Jebel Teir, having an active volcano, the summit of which is more than 1,000 ft. above the sea. Nearly S. of it is the Zebayer group. Kamaran island, off the coast of Yemen, is claimed by the British. In lat. 14° is Jebel Zugur, and in the straits of Bab-el-Mandeb, commanding the entrance from the Indian ocean, is Perim, a fortified British possession. (See PERIM.) At the entrance of the gulf of Akabah is the island of Tiran, dividing it into two channels, of which only the western one, called the strait of Tiran, is navigable for large vessels; and at the mouth of the gulf of Suez are Shadwan island and several smaller ones.—The Red sea occupies the bottom of a longitudinal valley lying between the highlands of

Arabia on the east and the mountain range on the west, which borders Abyssinia, Nubia, and Egypt. On the N. side, between the gulf of Suez and the Mediterranean, the country is low and flat, and exhibits indications that a communication once existed between the two seas. The mountains are in sight on both sides of the sea, but a considerable part of each coast is low and flat or covered with undulating hills, the mountain range being in some places 20 or 30 m. from the shore. It is probable that the sea once covered the entire basin, but has been filled up in part by the growth of coral and the accumulation of sand. The Arabian town of Muza, marked as a seaport in the *Periplus of Arrian*, is now several miles inland. The coral reefs, which are more extensive than in any other sea of equal size, lie generally in long lines parallel to the shores, and from 500 yards to a mile distant from them. The banks are usually from 4 to 6 ft. below the surface, and the water on their outer edge is very deep, but on the inner side they are sometimes connected with the land. Where they are unconnected with the shore there is generally a channel within them navigable for small vessels and having good anchorage. The native vessels make great use of these inner straits, where the heavy winds of the open sea affect them but little. There is no surf on the reefs, as the porous coral permits the passage of the waves through them. The reefs are more numerous on the E. than on the W. side. The growth of continental coral reefs in the Red sea in a more northerly latitude than elsewhere is accounted for by the absence of rivers on the coast, and by the high temperature of the water, which is seldom below 80° F. In March and April it is sometimes 84° , and in May 90° . The genera of coral are nearly the same as in the central Pacific, and consist of most of the reef-forming species. Some of the meandrinæ and faviæ are from 6 to 9 ft. in diameter. The coral is generally white, but often red, and a black variety is found along the Arabian coast for 50 m. N. and S. of Jiddah. Sponges of fine quality are taken in abundance along the E. shore of the gulf of Suez, and pearl oysters are found in various places. As the Red sea receives but little water from the atmosphere or from the surrounding country, and the sun's rays generally fall on it from a cloudless sky, it may be considered merely a basin for evaporation, which proceeds at the rate of about four fifths of an inch a day, or 23 ft. in a year. From a little more than 39 parts of salt in 1,000 at the straits of Bab-el-Mandeb, the proportion rises in the N. part to 43, a degree of saltiness found elsewhere only in inland salt lakes. As the concentration of so much salt through evaporation would tend in time to fill up the sea, it is supposed that the waters most charged with salt flow out through the straits in an undercurrent, while the lighter and less saline waters flow in above it.—The winds are generally pretty constant.

From October to May they blow from S. S. E., being strongest in February; the rest of the year they are from N. N. W., and the strongest in June and July. Sailing vessels find great difficulty in beating up against the wind from May to November, and the pilgrim ships from India are often obliged to put in at Hodeida and forward their passengers to Mecca and Medina by land. The tidal wave enters but a little way into the Red sea, and no ebb and flow of the tide is noticeable at the N. extremity. The currents seem to be governed entirely by the winds. When the S. wind blows the water flows toward the gulf of Suez, and the surface is 2 ft. higher than when the N. wind prevails; and after long continued N. winds the upper part of the gulf of Suez is sometimes fordable. In general the waters are at the same level with those of the Mediterranean. The atmosphere of the Red sea is very oppressive during the hot months. In the latitude of Jiddah the average day temperature from December to March is 76°; from March to the end of May, 87°; during June, 93°; in July, August, and September, 100°; and in October and November, 85°. When the S. wind blows in summer the temperature is frequently 107°, and during the simoom, which blows from N. E. and E. N. E., but generally for a few hours only, it sometimes rises to 132°.—The principal ports of the Red sea are: on the gulf of Suez, Suez and Tor; on the African coast, Kosseir, Suakin, and Massowa; and on the Arabian coast, Yambo, the port of Medina, Jiddah, the port of Mecca, Loheia, Hodeida, and Mocha. There are many other small harbors and inlets, frequented by the Arabs, who carry on most of the local commerce, and who from long experience are acquainted with all the intricacies of the coast navigation. There are several lighthouses: one on Perim, one on the Dædalus shoal, about 200 m. N. of Jiddah, one at Ras Sharib on the W. side of Jubal strait, and three in the gulf of Suez. There is a submarine telegraph cable from Aden to Suez through the Red sea, which since the completion of the canal has become once more the highway of travel and commerce between the Mediterranean and India. (See CANAL, and SUEZ.)—The Red sea is often referred to in the Hebrew Scriptures under the name of Yam Suph, the sea of weeds, so called, it is supposed, from a small seaweed thrown up by its waters, probably the *rytiphlea pinastroides*. The name Red is generally traced directly from the Latin *Rubrum* and Greek *Ἐρυθρά*, which were applied to this sea in common with the Persian gulf and Indian ocean by Herodotus and other ancient writers. (See ERYTHRÆAN SEA.) Its origin has been variously deduced from the redness of the surrounding hills, of the coral reefs, of the seaweed, and of the water from the presence of animalcules, from early Phœnician (Gr. *φαινέ*, red) dwellers on the shores of the Erythræan, and from Edom, "red,"

the Hebrew and Phœnician name of a country adjoining the gulf of Akabah. Himyar, the name of the founder of the Himyarite kingdom of S. W. Arabia, is supposed also to be derived from the Arabic *ahmar*, "red." The most interesting historical incident connected with the Red sea is the passage of the Israelites across it in their flight from Egypt. (See EXODUS.) By the Red sea in ancient times the trade between India and the countries on the Mediterranean was carried on; and upon this sea and the other inland gulfs and seas of this part of the old world the earliest commercial operations were conducted, and the first experience in navigation was gained. The Egyptians and Phœnicians established this trade with India, and so important was it to the former people, that the Pharaoh whom the Greeks call Sesostris is related to have had upon the Arabian gulf a fleet of 400 long vessels or ships of war, by means of which he protected it and subjugated the people on the borders of the sea who interfered with it. King Solomon built "a navy of ships in Ezion-geber, which is beside Elath, on the shore of the Red sea, in the land of Edom." (1 Kings ix. 26.) Ezion-geber was at the head of the gulf of Akabah, and these ships constituted the fleet which went to Ophir. For a long time the Heroöpolite gulf or gulf of Suez was the chief avenue of the Egyptian traffic; but the shoaling of the water at the head rendered navigation dangerous, and in the reign of Ptolemy Philadelphus this route was nearly abandoned in favor of that by way of the new port of Berenice, near lat. 24°, which was connected by a well constructed road with Coptos on the Nile, whence boats conveyed the merchandise to Alexandria. Myos-Hormos, about lat. 27° 20', was also an important port under the Ptolemies and the Romans, and according to Strabo 120 ships left it annually for India. After the Mohammedan conquest of Egypt, a large commerce was carried on by the Arabs through the Red sea with India and China. In the middle ages the Genoese and Venetians were largely engaged in this trade, until the discovery by the Portuguese of the route by the cape of Good Hope, when the Red sea lost its commercial importance. This was in part revived when the English established the overland route to India, *via* the Cairo and Suez railway; and since the opening of the Suez canal this ancient route has once more assumed its former importance.

REDSHID PASHA. See RESHID PASHA.

REDSTART, the common name of an American and a European genus of birds of the warbler family. In the American genus, *setophaga* (Swains.), the bill is as in the flycatchers (in which family they are included by some authors), and abruptly curved and notched at the tip; the wings rounded, with the second to fourth quills longest; tail long, graduated, and broad; tarsi and toes short. There are many species, mostly in South and Central America, brilliantly marked with red,

yellow, and black; the South American species have more or less yellow in their plumage, and the Mexican are usually black and red. The best known species in North America is the common redstart (*S. ruticilla*, Swains.), of the subfamily *syloicolinae*; it is about 5½ in.

American Redstart (*Setophaga ruticilla*).

long with an alar extent of 8 in.; in the male the prevailing color is black, with the base of the wings and tail and sides of breast reddish orange; abdomen, under tail coverts, and central line on breast white; in the female the black is replaced by olive-green above and brownish white below, the head is ashy, and the red is changed to yellow. It is found throughout the eastern United States to the plains of the Missouri, and sometimes wanders to the West Indies in winter; it is very handsome, always in motion on the trunks and branches of trees in search of insects and larvæ, jumping quickly from side to side, displaying the brilliant tail at every movement, and now and then darting off after an insect on the wing, or descending to the ground in a spiral or zigzag manner; it pursues other birds as if in sport, snapping the bill violently. The nest is placed in a low bush, suspended to the twigs, and is of delicate structure; the eggs are four to six, white, with ash-gray and blackish spots; a single brood is raised in a season.—The European redstart belongs to a different subfamily of the warblers, that of the *erythacinae*, and to the genus *ruticilla* (Brehm), peculiar to the old world. The *R. phanicura* (Brehm) is a little more than 5 in. long; in the male the bill, legs, feet, cheeks, and throat are black; the breast, rump, and sides red; forehead white; crown, hind neck, and back deep blue-gray. It occurs all over Europe, and is a visitor to Great Britain from April to September; it is a very fine songster, heard the summer long in orchards, hedge rows, gardens, and ivy-covered walls; the male is very affectionate, and sometimes sings to his mate as late as

ten at night and as early as three in the morning; it feeds on insects, worms, and berries; the eggs, four to six, are greenish blue, and laid in holes of trees or in a nest on the ground. It is much prized as a cage bird; if taken young, it may be taught to imitate the notes of most other birds, and even to whistle a tune. The name in both hemispheres is derived from the constant jerking motions of the bird, displaying the red of the tail.

RED WILLOW, a S. county of Nebraska, bordering on Kansas, formed since the census of 1870; area, 720 sq. m. It is intersected by the Republican river and its branches. The surface is undulating or level.

REDWOOD. See **SANDAL WOOD**, and **SEQUOIA**.

REDWOOD, a S. W. county of Minnesota, bounded N. E. by the Minnesota river, and intersected by the Redwood, Sleepy Eye, and Big Cottonwood rivers; area, about 1,100 sq. m.; pop. in 1870, 1,829. The surface is uneven and consists largely of prairies; the soil is good. The chief productions in 1870 were 5,409 bushels of wheat, 2,240 of Indian corn, 6,978 of oats, 1,880 of potatoes, and 882 tons of hay. Capital, Redwood Falls.

REED (*A. S. hreed*), a name of tall coarse grasses, especially of the genera *phragmites* and *arundo*. The common reed of this country and England was called *arundo phragmites* by Linnaeus, but later botanists have considered it sufficiently distinct to form a new genus *phragmites* (Gr. *φραγμιτες*, growing in hedges, though the plant is an aquatic), but some still retain it in *arundo*; in recent American works it is given as *P. communis*. It is a stout per-

Common Reed (*Phragmites communis*).

ennial grass, 6 to 12 ft. high, with numerous broad leaves, and bearing a large terminal, purplish brown panicle, which is sometimes a foot long, very loose and nodding; each spikelet consists of three to seven flowers, surrounded by long silky hairs. This is found over a

large part of both continents, on the edges of ponds, in ditches and marshes, and where it occurs abundantly looks at a distance like a field of broom corn. In Europe the reed is utilized in various ways; it is planted by the margin of streams in order that its long and branching rootstocks may bind the soil and prevent the encroachment of the water upon the banks; animals will eat the herbage when quite young, but it soon becomes too tough for them. In northern Europe the stems are valued for thatching, being much more durable than straw, and rude huts are sometimes constructed from them; and they are used for making hurdles and for other domestic purposes, among which is that of weaving mats for screening wall fruit, covering hotbeds, and protecting plants in various ways; it is said that the flower panicles are used in Sweden to afford a greenish dye. As the plants form dense and tall thickets, they afford protection to various water and marsh birds and quadrupeds. In ornamental grounds where there is a moist locality, the reed may be introduced with good effect as an ornamental plant.—The Cyprus reed, *arundo donax*, is a much more robust plant, growing 15 ft. or more high, with abundant leaves and very large terminal panicles of a brownish white color; it is found in southern Europe, eastern Asia, western Africa, and on this continent in Mexico and Texas; and it is apparently the reed mentioned in Scripture. It is used as supports for vines, for fishing poles, and various other purposes. There is a variegated form, *A. donax versicolor*, in which the leaves are marked with very distinct bands of white and green; it is one of the best of variegated plants, holding its markings under the hottest sun, but it does not grow so tall as the green kind. Both forms are occasionally seen in northern gardens, where it is necessary to give their roots a good covering of litter when winter sets in.—The large reed or cane of the southern states is described under CANEBRAKE.—Sea reed is *calamagrostis arenaria* (*ammophila* of some authors), a coarse rigid grass 2 to 3 ft. high, with abundant firm running rootstocks; it is frequent on the coast of Europe, and on our shores from New Jersey to Maine, and along the great lakes. The plant is capable of being utilized to retain blowing sands. Besides the names above given, it has been called *psamma* and *maram* by authors.

REED, Andrew, an English clergyman, born in London, Nov. 27, 1788, died there, Feb. 25, 1862. He studied at Hackney college, and in 1811 was ordained pastor of the Independent congregation in New Road chapel. In 1831 he removed with his congregation to Wycliffe chapel, Stepney, where he continued till his death. In 1834 he was deputed, with the Rev. James Matheson, by the Congregational union of England and Wales, to visit the United States and report on the state of religion and education there; and on his return he pub-

lished with Mr. Matheson "Visit to the American Churches" (2 vols., New York and London, 1836). He founded the London orphan asylum in 1813, the infant orphan asylum in 1827, the asylum for fatherless children at Croydon, the asylum for idiots at Reigate, and the royal hospital for incurables, and left bequests to these institutions. He published "No Fiction" (London, 1818; 24th ed., 1860); "Martha" (1836); "The Day of Pentecost" (1839); "The Revival of Religion," and "Earnest Piety essential to Eminent Usefulness" (1839); and "Advancement of Religion the Claim of the Times" (1847).—See "Memoirs of the Life and Labors of Andrew Reed, D. D." (1863), by his sons Charles and Andrew. The former is a proprietor of the London "Daily News" and president of the Sunday school union of England and Wales; he was elected to parliament in 1872, and in 1873 was a delegate to the conference of the evangelical alliance in New York.

REED, Henry, an American author, born in Philadelphia, July 11, 1808, died Sept. 27, 1854. He graduated at the university of Pennsylvania in 1825, was admitted to the bar in 1829, and in 1835 became professor of rhetoric and English literature in the university of Pennsylvania, retaining this post till his death. In the spring of 1854 he visited Europe, and on his return voyage was lost in the steamer Arctic. He wrote the life of his grandfather Joseph Reed, in Sparks's "American Biography;" "Lectures on English Literature from Chaucer to Tennyson" (1855); "Lectures on English History and Tragic Poetry, as illustrated by Shakespeare" (1855); and "Lectures on the British Poets" (1857).

REED, Joseph, an American patriot, born in Trenton, N. J., Aug. 27, 1741, died in Philadelphia, March 5, 1785. He graduated at the college of New Jersey in 1757. In 1763 he went to England, where he studied law until the troubles produced by the stamp act began, when he returned to Trenton, entered upon the practice of his profession, and in 1767 was appointed deputy secretary of New Jersey. Revisiting England in 1770, he married a daughter of Mr. Dennis De Berdt, agent for the province of Massachusetts Bay, and on his return settled at Philadelphia, took an active part on the side of independence in the political struggles of the time, and through his English connections opened a lengthened correspondence on the subject with Lord Dartmouth, secretary for the colonies. In 1774 he was appointed a member of the committee of correspondence, and in January, 1775, president of the first provincial convention held in Pennsylvania; and he was a delegate to the continental congress which met in May. On the formation of the army he was appointed aide-de-camp and secretary to Gen. Washington. In 1776 he was made adjutant general, and by his local knowledge contributed to the successes at Trenton and Princeton. In 1777

he was appointed chief justice of Pennsylvania, and named by congress a brigadier general; but he declined both offices, and continued to serve in the army as a volunteer, without rank or pay. He was present at most of the engagements in the northern and eastern portions of the Union. In 1778 he was elected to congress, and signed the articles of confederation. About this time he was approached by one of three British commissioners, Gov. Johnstone, with an offer of £10,000 and the most valuable office in America, if he would exert himself to promote a reconciliation between Great Britain and the colonies. His answer was: "I am not worth purchasing; but, such as I am, the king of Great Britain is not rich enough to buy me." He was president of the supreme executive council of Pennsylvania in 1778-'81, and was efficient in suppressing an armed insurrection that occurred in Philadelphia, and a revolt of the Pennsylvania line. He aided in founding the university of Pennsylvania. His "Life and Correspondence" was published by his grandson W. B. Reed (2d ed., Philadelphia, 1847); and his grandson Henry Reed wrote his life in Sparks's "American Biography" (2d series, vol. viii., 1848).

REED BIRD. See BOBOLINK.

REED INSTRUMENTS, among musical contrivances, a numerous and diverse class, including all those the tones of which are due to vibrations imparted to a body of air in a tube, throat, or chamber, by means of the pulsations of a thin lamina or tongue of wood or metal having one end fixed and the other lying over or within an aperture, and actuated by forcibly directing through this a current of air. Technically, such a lamina is termed a reed. It has two general forms. In the first, seen in the clarinet, the reed is larger than the opening through which the air is to pass, and in pulsating alternately closes and opens it, beating against its margins. This form, among European nations doubtless the earliest known, is distinguished as the beating reed. In the second, seen in the accordion, the dimensions of the reed are slightly less than those of the aperture, so that, in pulsating in consequence of an impulse and of its own elasticity, it moves within the current of air only, alternately allowing and interrupting its passage; this is hence termed the free reed. It is proposed to consider in this place only those instruments involving the free reed.—A small, short, metallic tube, containing a single tongue or reed of this form, fitted to yield upon blowing into one end the note A or O, has long been known, and probably first in Germany and Holland, and is termed a pitch pipe. Père Amiot, a French missionary to China, early described the *cheng*, or Chinese organ, a small instrument consisting of a series of tubes, each having its free lamina or tongue, and acted on by the breath of the performer; and this appears to have been in common use in that country from an early period. The accordion was in-

vented in Germany about 1829. The first reed organs, though imperfect, were made in the United States about 1818. Indeed, as early as 1812 Aaron Merrill Peasley obtained a patent for reed instruments; the wording of his claim was sufficiently general to include any form of instrument in which the tones are produced by free reeds caused to vibrate by a bellows and played by a keyboard. This patent is now in possession of the Mason and Hamlin organ company. Mr. J. H. Bazin of Canton, Mass., in 1821, is named as the second inventor. At first the instruments attracted but little attention, owing to their defective construction. Wherever the free reed may have been first applied to the making of a small or hand instrument, the modifications thence arising, especially between about 1825 and 1835, were in rapid succession and numerous. Among the earliest of these were Wheatstone's *æolina* and concertina, the latter in form of a bellows with two hexagonal faces, on the upper of which were four rows of finger stops or studs; by pressing down the latter, air was admitted to act on the corresponding tongues within. The attempts to improve the accordion, by enlarging it and extending its scale, naturally rendered it unwieldy, and thus led to a form of organ with free reeds only, and without pipes, the bellows being worked by the foot. Such were Mr. Green's *seraphine* and the French *mélodivm* (in England and the United States, *melodeon*), one form of which latter, also termed the harmonium, appears to have been the invention of M. Debain of Paris, and improved by MM. Alexandre, father and son. The most improved form of this instrument is now known in France as the *orgue-mélodivm*, or *piano Liszt*; in this country, as the Alexandre organ. Other French instruments, of the earlier date above spoken of, were the *poikilorgue* and *symphonivm*; of the German, some of which were small, and probably all ephemeral, were the *æolophon*, *phys-harmonica*, *æolo-musicon*, &c. In 1841 Mr. Evans of Cheltenham, England, produced a harmonium of two banks of keys and $2\frac{1}{2}$ octaves of pedals; but the instrument was not brought prominently forward till 1859. The objects of this inventor were to overcome the nasal and harsh quality of tone, and the slow speaking, then characterizing the French and English instruments; and he is said to have produced ultimately a pure tone of fine quality, with rapid utterance, and without loss of power. This is the form of harmonium described in English works. In it the several rows or series of reeds designed to give the different registers or parts in the harmony performed are, as in the Alexandre organ, placed horizontally across the instrument, at the same level, and separated from each other by partitions; the arrangement being such that the particular compartments or series to which the air shall be admitted in performing are determined by the knobs or stops that have been drawn

out at the time. (See ORGAN.) In the English, as in the French instruments, also, the tardy response of the reeds to the action of air is corrected in most instances by a device known as the percussion, by which, the proper stop being drawn, the touching of any key instantly causes the blow of a small hammer on the reed, its vibration, thus promptly begun, being then continued by the current of air. In all these forms, moreover, the agitation of the reeds is produced by means of more dense or compressed air forced out of a bellows across the reeds, and acting of course against the ordinary atmospheric pressure on the opposite side; and generally the reeds themselves are placed low in the instrument, often beneath the keyboard, so that the sound is liable to be somewhat smothered or interfered with. Some radical improvements were invented by Mr. J. Carhart (see MELODEON), the changes introduced by him having been worked out as early as 1836, and his instruments being manufactured in large numbers in Buffalo, N. Y., in the year 1846. In the application for his patent Mr. Peasley had stated that the reeds might be caused to vibrate by a force or an exhaust bellows, but that he preferred the latter. The instrument did not however come into extensive use until improved by Mr. Carhart. On the principle of the superior fulness and sweetness of those tones in the accordion made when the air is drawn into the bellows, as compared with those formed by forcing the air out, he so constructed the bellows of the melodeon that it should expel the air from the chamber into which the reed passages opened; this chamber and the space within the bellows freely communicating, and being maintained while playing in the condition of a partial vacuum by means of stout springs, which gradually distend the bellows as often as force has been used to compress and empty it of the entering air. This required that the reeds also should be reversed, the passages admitting air into the exhausted chamber, and the reeds being acted on by the in-flowing streams of air. As a result of this arrangement, all the registers open directly into the one exhausted chamber; and they are conveniently placed in rows one over the other in the manner of shelves or successive segments, each horizontal row divided in the middle to form two registers. The construction of this part of the instrument finally adopted and now in use is the invention of Mr. E. P. Needham. Again, to open the registers, complicated connections and slides are not required, but simply for each a narrow horizontal door hinged on its lower edge, and directly pulled down by a wire making a single angle with the draw-knob. The chamber being during performance partially exhausted, if the edges of the several upright shelves or segments and of the horizontal doors to the registers are properly adapted and faced with soft leather, the external atmospheric pressure

completes the connection of these parts, and secures air-tightness and strength of the whole; while in other instruments the condensed air within operates continually to strain and weaken the connections. Thus, in this instrument, the parts are readily removed for repairs, being stayed by pins only, and as quickly put together again; and the reeds are thus directly accessible. The closing of any register is made to open a small valve within it, called a pneumatic stop, by which communication with the exhausted chamber is at once made both above and below the reeds, and the latter are then within the exhausted chamber; but upon opening the register, this valve closes, and thus other communication is cut off above, and the reeds have the exhausted space now only within, the atmosphere acting from without. The touching of any key is made to open (if the instrument has but one bank of keys) the corresponding valve in every register. When all the registers are open, all the reeds so uncovered are caused by the entering air to sound; if some of the registers only are open, only the reeds in these can sound. With two banks of keys, couplers are required in order to put all the registers at pleasure under command of one. When by couplers the keys have thus been connected with valves in all the registers, the drawing of the knob *grand jeu*, or grand organ, opens all the registers, and affords remarkable power of tone and effect. These arrangements are more common in the larger instruments or harmoniums.—The art of voicing reeds by variously curving and twisting them was invented about 1848, by Mr. Emmons Hamlin of Rome, N. Y., and first applied by the Mason and Hamlin organ company of Boston, New York, and Chicago. This invention has greatly contributed to the present perfection of these instruments, increasing the volume and improving the quality of the tones, and producing some of the differences required for the different registers. It is indeed asserted by the German makers that it was previously known in Europe; but it was not successfully employed there until after the Paris exposition of 1855, where the American reed organs created a lasting sensation. In any reed, the rapidity of vibration, and hence the pitch, depend on several particulars, chiefly the length and weight of the reed, and its relative thickness at the two ends. If the reed is thick at the free end and thin at the fixed, its tone is deep; if the reverse, acute. Hence, the reeds are roughly attuned by giving them certain lengths and thicknesses, and then more accurately by scraping off a little as may be required from the free or the fixed extremity. The Alexandre organ is made of different sizes, the largest corresponding to a 16-ft. pipe organ, and by combinations giving seven octaves. Its usual stops are the English horn and flute, and again the bassoon and hautboy, forming the ordinary diapasons, and answering to the compass from an 8-ft. pipe; drone and clarinet,

an octave below; clarion and fife, an octave above; two forte stops, to increase the volume of sound; a principal, which opens all the stops at once; the two stops first named also actuating the percussion; and two stops, *expression à la main* and expression of pedals, by which superior power of expression, or swell and diminuendo, is secured by merely varying the pressure of the fingers or of the feet. With these are also introduced the *sourdine*, modifying the tone of certain stops, *voix céleste*, *voix humaine*, *musette*, *forte*, *tremolo*, and combination swell. In 1870 nearly 30,000 of these instruments were manufactured in the United States.

REES, Abraham, a British scholar, born at Llanbrynmair, Wales, in 1743, died June 9, 1825. He studied for the ministry at Hoxton academy, near London, and was appointed tutor there in his 19th year, which post he retained for more than 22 years. In 1768 he became also pastor of a Presbyterian congregation in Southwark, and in 1783 in the Old Jewry. From 1786 to 1795 he was also president of the dissenting academy at Hackney. He was a fellow of the royal society of London, and of the Linnean society. Many of his sermons were published. In 1776 he was engaged to edit a new edition of Chambers's "Cyclopædia," which was completed in 1786 (4 vols. fol.); and in 1802 he began "Rees's Cyclopædia," which was completed in 45 vols. 4to in 1819.

REEVE. See **RUFF**.

REEVES, Sims, an English singer, born in Woolwich in 1821. He received his earliest instruction from his father, from H. Callcott lessons in harmony, from J. B. Cramer on the piano, and from Hobbs and T. Cooke in singing. His early vocal instructors mistook the character of his voice, developing it as a baritone, and at 19 Reeves made his début at Newcastle-on-Tyne as Rudolpho in *La sonnambula*. Later he took lessons of Bordogni in Paris, who corrected the mistake as to the quality of his voice, and brought out its true character, that of a tenor of great range. He completed his musical education under Mazzucato at Milan, and before leaving that city appeared at La Scala as Edgardo in *Lucia di Lammermoor*. He made his début in London, at Drury Lane, Dec. 6, 1847, in the same rôle. At the Norwich musical festival in the autumn of 1848 he showed a faculty for interpreting the works of Handel, Haydn, and Mendelssohn, which has made him the leading oratorio tenor in England. He continued to sing with increasing reputation in Italian and English opera and in concert and oratorio till 1856, since which he has sung chiefly in the concert room.

REFORMATION, the historical name for the great religious movement of the 16th century, which divided the Latin Catholic church into two opposing sections, and resulted in the establishment of the various ecclesiastical organizations of evangelical or Protestant Christen-

dom. There were many "reformers before the reformation," and almost every doctrine of Luther had its advocates long before him. The whole struggling of mediæval Catholicism toward reform and liberty; the long conflict between the German emperors and the popes; the reformatory councils of Pisa, Constance, and Basel; the Waldenses and Albigenses in France and northern Italy; Wycliffe and the Lollards in England, Huss and the Hussites in Bohemia, Arnold of Brescia, and Savonarola with his politico-religious reform movement, in Italy; the spiritualistic piety and theology of the mystics of the 14th and 15th centuries; the theological writings of Wesel, Goch, and Wessel in Germany and the Netherlands; the rise of the national languages and letters in connection with the feeling of national independence; the invention of the printing press; the revival of letters and classical learning under the direction of Agricola, Reuchlin, and Erasmus; all these and many similar persons and movements were so many preparations for the reformation of the 16th century. The reformation was originally neither a political nor a philosophical nor a literary, but a religious and moral movement. It started with the practical question: How can the troubled conscience find pardon and peace, and become sure of personal salvation? It retained from the Catholic system all the objective doctrines of Christianity concerning the Holy Trinity and the divine-human character and work of Christ—in fact, all the articles of faith contained in the apostles' and other œcumenical creeds of the early church. But it joined issue with the prevailing system of religion in soteriology, or in the doctrines relating to subjective experimental Christianity, especially the justification of the sinner before God, the true character of faith, good works, the rights of conscience, and the rule of faith. It asserted the principle of evangelical freedom as laid down in the epistles of Paul to the Romans and Galatians, in opposition to the system of outward legalistic authority which held the individual conscience and private judgment bound. It brought the believer into a direct relation and union with Christ as the one and all-sufficient source of salvation, in opposition to traditional ecclesiasticism, and priestly and saintly intercession. The Protestant goes directly to the word of God for instruction, and to the throne of grace in his devotions; while the pious Catholic always consults the teaching of his church, and often prefers to offer his prayers through the medium of the Virgin Mary and the saints. From this general principle of evangelical freedom and direct individual relationship of the believer to Christ proceed the two fundamental doctrines of Protestantism, the absolute supremacy of the word of Christ, and the absolute supremacy of the grace of Christ. The one is called the formal principle, or *principium cognoscendi*; the other the material prin-

ciple, or *principium essendi*. The former proclaims the canonical Scriptures (to the exclusion of the Apocrypha of the Old Testament), and more particularly the word of Christ and the apostles, to be the only and sufficient infallible source and rule of faith and practice, and asserts the right of private interpretation of the same; in distinction from the Roman Catholic view, which declares the Bible and tradition or church authority to be two coördinate sources and rules of faith, and makes tradition, especially the decrees of popes and councils, the only legitimate and infallible interpreter of the Bible. In its extreme form Chillingworth expressed this principle of the reformation in the well known formula: "The Bible, I say, the Bible only, is the religion of Protestants." Genuine Protestantism, however, by no means despises or rejects church authority as such, but only subordinates it to and measures its value by the Bible, and believes in a progressive interpretation of the Bible through the expanding and deepening consciousness of Christendom. Hence, besides having its own symbols or standards of public doctrine, it retained all the articles of the ancient Catholic creeds and a large amount of disciplinary and ritual tradition, and rejected only those doctrines and ceremonies of the Catholic church for which it found no clear warrant in the Bible, or which it thought contradicted its letter or spirit. The Calvinistic branches of Protestantism went further in their antagonism to the received traditions than the Lutheran and the Anglican reformation; but all united in rejecting the authority of the pope (Melanchthon for a while was willing to concede this, but only *jure humano*, as a limited disciplinary superintendency of the church), the meritoriousness of good works, the indulgences, the worship of the holy Virgin and of the saints and relics, the seven sacraments with the exception of baptism and the eucharist, the dogma of transubstantiation and the sacrifice of the mass, purgatory and prayers for the dead, and the use of the Latin language in public worship, for which the vernacular languages were substituted. The other fundamental doctrine of the reformation has reference to the personal appropriation of the Christian salvation, and has for its object to give all glory to Christ by declaring that the sinner is justified before God, *i. e.*, acquitted of guilt and declared righteous, solely on the ground of the all-sufficient merit of Christ as apprehended by a living faith; in opposition to the theory, then prevalent and substantially sanctioned by the council of Trent, which makes faith and good works the two coördinate sources of justification. Genuine Protestantism does not, on that account, by any means reject or depreciate good works; it only denies their value as sources or conditions of justification, but insists on them as the necessary fruits of faith and evidence of justification. To these two prominent principles

of the reformation, which materially affect its theology and religious life, must be added the doctrine of the universal priesthood of believers, and the right and duty of the laity not only to read the Bible in the vernacular tongue, but also to take part in the government and all the public affairs of the church. —We now present an outline of the history of the reformation in the various countries in which it finally succeeded, leaving out Bohemia, Italy, and Spain, where it was suppressed by the combined opposition of the secular and ecclesiastical authorities. I. THE REFORMATION IN GERMANY. The movement in Germany was directed by the genius and energy of Luther and the learning and moderation of Melanchthon, assisted by princes, especially the electors of Saxony, and sustained by the majority of the people in spite of the opposition of the bishops and the imperial government. It commenced in the university of Wittenberg with the protest against the traffic in indulgences, Oct. 31, 1517 (ever since celebrated in Protestant Germany as the festival of the reformation), and soon became a powerful popular movement. At first it moved within the bosom of Catholicism. Luther shrunk in holy horror from the idea of a separation from the religion of his fathers. He only attacked a few abuses, taking it for granted that the pope himself would condemn them if properly informed. But the irresistible logic of events carried him far beyond his original intentions, and brought him into irreconcilable conflict with the central authority of the church. Pope Leo X., in June, 1520, pronounced the sentence of excommunication against Luther, who burned the bull together with the canon law and several books of his opponents. The diet of Worms in 1521, where he made his memorable defence, added to the excommunication of the pope the ban of the emperor. But the dissatisfaction with the various abuses of Rome and the desire for the free preaching of the gospel were so extensive, that the reformation both in its negative and positive features spread in spite of these decrees, and gained a foothold before 1530 in the greater part of northern Germany, especially in Saxony, Brandenburg, Hesse, Pomerania, Mecklenburg, Lüneburg, Friesland, and in nearly all the free cities, as Hamburg, Lübeck, Bremen, Magdeburg, Frankfort, and Nuremberg; while in Austria, Bavaria, and along the Rhine it was persecuted and suppressed. Among the principal causes of this rapid progress were the writings of the reformers, Luther's German version of the Scriptures, and the evangelical hymns, which introduced the new ideas into public worship. The diet of Spire in 1526 left each state to its own discretion concerning the question of reform until a general council should settle it for all, and thus sanctioned the principle of territorial independence in matters of religion which prevails in Germany to this day, each sover-

eighty having its own separate ecclesiastical establishment and organization in close union with the state. But the next diet of Spire, in 1529, prohibited the further progress of the reformation. Against this decree of the Catholic majority the evangelical princes entered, on the ground of the word of God, the inalienable rights of conscience, and the decree of the previous diet of Spire, the celebrated protest, dated April 19, 1529, which gave rise to the name of Protestants. The diet of Augsburg in 1530, where the Lutherans offered their principal confession of faith, drawn up by Melancthon and named after that city, threatened the Protestants with violent measures if they did not return shortly to the old church. Here closes the first and most eventful period of the German reformation. The second period embraces the formation of the Protestant league of Smalcald for the armed defence of Lutheranism, the various theological conferences of the two parties for an adjustment of the controversy, the death of Luther, the imperial interims or compromises (the Ratisbon, Augsburg, and Leipsic interims), and the Smalcaldian war, and ends with the success of the Protestant army under Maurice of Saxony and the peace of Augsburg in 1555, which secured to the Lutheran states the free exercise of their religion, but with a restriction on its further progress. The third period, from 1555 to 1580, is remarkable for the violent internal controversies of the Lutheran church: the Osiandrian controversy, concerning justification and sanctification; the adiaphoristic, arising originally from the fruitless compromises or interims; the synergistic, concerning faith and good works; and the crypto-Calvinistic or sacramentarian controversy about the real presence. These theological disputes led on the one hand to the full development of the doctrinal system of Lutheranism as laid down in the "Book of Concord" (first published in 1580), which embraces all the symbolical books of that church, namely, the three oecumenical creeds, the Augsburg confession and its "Apology" by Melancthon, the two catechisms of Luther and the Smalcald articles drawn up by him in 1537, and the "Formula of Concord," composed by six Lutheran divines in 1577. But on the other hand, the fanatical intolerance of the strict Lutheran party against the Calvinists and the moderate Lutherans, called after their leader Melancthonians or Philippists, drove a large number of the latter over to the Reformed church, especially in the Palatinate (1560), in Bremen (1561), Nassau (1582), Anhalt (1596), Hesse-Cassel (1605), and Brandenburg (1614). The German Reformed communion adopted the Heidelberg catechism, drawn up by two moderate Calvinistic divines, Zacharias Ursinus and Kaspar Olevianus, in 1562, by order of the elector Frederick III. or the Pious, as their confession of faith. The 16th century closes the theological history of the German reformation; but its political his-

tory was not brought to a final termination until after the terrible thirty years' war, by the treaty of Westphalia in 1648, which secured to the Lutherans and the German Reformed churches (but to no others) equal rights with the Roman Catholics within the limits of the German empire. Those two denominations, either in their separate existence or united in one organization (as in Prussia and other states since 1817), are to this day almost the only forms of Protestantism recognized and supported by the German governments, all others being small self-supporting sects, regarded with little sympathy by the popular mind. But within those ecclesiastical establishments Germany has bred and tolerated during the present century almost every imaginable form of theoretic belief, from the strictest old school orthodoxy to the loosest rationalism and skepticism. Since the third jubilee of the reformation (1817), however, there has been a gradual and steady return from neology to the original evangelical Protestantism. II. THE REFORMATION IN SWITZERLAND. This was contemporaneous with, but independent of, the German reformation, and resulted in the formation of the Reformed communion as distinct from the Lutheran. In all the essential principles and doctrines, except that on the mode of Christ's presence in the eucharist, the Helvetic reformation agreed with the German; but it departed further from the received traditions in matters of government, discipline, and worship, and aimed at a more radical moral and practical reformation of the people. It naturally divides itself into three periods: the Zwinglian, from 1516 to 1531; the Calvinistic, to the death of Calvin in 1564; and the period of Bullinger and Beza, to the close of the 16th century. The first belongs mainly to the German cantons, the second to the French, the third to both jointly. Zwingli began his reformatory preaching against various abuses at Einsiedeln in 1516, and then with more energy and effect at Zürich in 1519. His object was to "preach Christ from the fountain," and to "insert the pure Christ into the heart." At first he had the consent of the bishop of Constance, who assisted him in putting down the sale of indulgences in Switzerland, and he stood even in high credit with the papal nuncio. But a rupture occurred in 1522, when Zwingli attacked the fasts as a human invention, and many of his hearers ceased to observe them. The magistrates of Zürich arranged a public disputation in January and another in October, 1523, to settle the whole controversy. On both occasions Zwingli, backed by the authorities and the great majority of the people, triumphed over his papal opponents. In 1526 the churches of the city and the neighboring villages were cleared of images and shrines, and a simple, almost puritanic mode of worship took henceforward the place of the Roman Catholic mass. The Swiss diet took a hostile attitude to the Reformed movement, similar

to that of the German diet, with a respectable minority in its favor. To settle the controversy for the republic, a general theological conference was arranged and held at Baden, Aargau, in May, 1526, with Dr. Eck, the famous antagonist of Luther, as the champion of the Roman, and Ecolampadius of the Reformed cause. Its result was in form adverse, but in fact favorable to the cause of the reformation. It was now introduced in the majority of the cantons, at the wish of the magistrates and the people; by Ecolampadius in Basel and Haller in Bern, also in part in St. Gall, Schaffhausen, Glarus, Appenzell, Thurgau, and the Grisons; while in the French portions of Switzerland William Farel and Viret prepared the way for Calvin. But the small cantons around the lake of Lucerne, Uri, Schwytz, Unterwalden, Lucerne, and Zug, steadfastly opposed every innovation. At last it came to an open war between the Reformed and Catholic cantons. Zwingli's policy was overruled by the apparently more humane, but in fact more cruel and disastrous policy of Bern, to force the poor mountaineers into measures by starvation. The Catholics, resolved to maintain their rights, attacked and routed the small army of Zürichers in the battle of Cappel, October, 1531. Zwingli, who had accompanied his flock as chaplain and patriot, met a heroic death on the field of battle, and Ecolampadius of Basel followed him in a few weeks. Thus the progress of the reformation was suddenly arrested in the German portions of Switzerland, and one third of it remains Catholic to this day. But it took a new start in the western or French cantons, and rose there to a higher position than ever. Soon after this critical juncture the great master mind of the Reformed church, who was to carry forward, to modify, and to complete the work of Zwingli, and to rival Luther in influence, began to attract the attention of the public. John Calvin, a Frenchman by birth and education, but exiled from his native land for his faith, found providentially a new home in 1536 in the little republic of Geneva, where Farel had prepared the way. Here he developed his extraordinary talents and energy as the greatest divine and disciplinarian of the reformation, and made Geneva the model church for the Reformed communion, and a hospitable asylum for persecuted Protestants of every nation. His theological writings, especially the "Institutes" and "Commentaries," exerted a formative influence on all Reformed churches and confessions of faith; while his legislative genius developed the presbyterian form of government, which rests on the principle of ministerial equality and of a popular representation of the congregation by lay elders, aiding the pastors in maintaining discipline and promoting the spiritual prosperity of the people. Calvin died after a most active and devoted life in 1564, and left in Theodore Beza (died 1605) an able and worthy successor, who partly with Bullinger, the faithful suc-

cessor of Zwingli in Zürich, and author of the second Helvetic confession (1566), labored to the close of the 16th century for the consolidation of the Swiss reformation and the spread of its principles in France, Holland, Germany, England, and Scotland. III. THE REFORMATION IN FRANCE. While the reformation in Germany and Switzerland carried with it the majority of the population, it met in France with the united opposition of the court, the hierarchy, and the popular sentiment, and had to work its way through severe trial and persecution. The tradition in that country was favorable to a change, as France had always maintained a certain degree of independence of Rome, and as the university of Paris, once the centre of European intelligence and culture, had strongly urged a thorough reformation *in capite et membris* on the councils of the 15th century. The first professed Protestants in France were Lefèvre, Wolmar, Farel, Viret, Marot, Olivetan, Calvin, and Beza, all men of distinguished learning and ability; but most of them had to seek safety in exile. It was only after the successful establishment of the reformation in French Switzerland that the movement became serious in the neighboring kingdom. Calvin and Beza may be called the fathers of the French Reformed church. Their pupils returned as missionaries to their native land. The first Protestant congregation was formed at Paris in 1555, and the first synod held in the same city in 1559. In 1561 the theological conference at Poissy took place, where Theodore Beza eloquently but vainly pleaded the cause of the Protestants before the dignitaries of the Roman church, and where the name Reformed originated. In 1571 the general synod at La Rochelle adopted the Gallican confession and a system of government and discipline essentially Calvinistic, yet modified by the peculiar circumstances of a church not in union with the state, as in Geneva, but in antagonism with it. The movement here unavoidably assumed a political character, and led to a series of civil wars which distracted France till the close of the 16th century. The Roman Catholic party, backed by the majority of the population, was headed by the dukes of Guise, who derived their descent from Charlemagne and looked to the throne, then occupied by the house of Valois. The Protestant (or Huguenot) party, numerically weaker, but containing some of the noblest blood and best talent of France, was headed by the princes of Navarre, the next heirs to the throne and descendants of Hugh Capet. The queen regent Catharine, during the minority of her sons, Francis II. and Charles IX., although decidedly Roman Catholic in sentiment, tried to keep the rival parties in check in order to rule over both. But the champions of Rome took possession of Paris, while the prince of Condé occupied Orleans. Three civil wars followed in rapid succession, when the court and the duke of Guise resorted to treason, and concerted a

wholesale slaughter of the Huguenots, Aug. 24, 1572, the leaders of the party having been expressly invited to Paris to attend the marriage of Prince Henry of Navarre with a sister of Charles IX. as a general feast of reconciliation. (See BARTHOLOMEW, SAINT, MASSACRE OF, and HUGUENOTS.) But the party was only diminished in number, by no means annihilated. Other civil wars followed with varying fortune, and terminated at last in the victory of Prince Henry of Navarre, who, after the assassination of Henry III. in 1589 by a Dominican monk, became king of France as Henry IV. This seemed to decide the triumph of Protestantism in France. But the Roman party, still more numerous and powerful, and supported by Spain and the pope, elected a rival head and threatened to plunge the country into new bloodshed. Then Henry, from political and patriotic motives, but apparently not from religious conviction, abjured the Protestant faith, in which he had been brought up, and professed the Roman Catholic religion (1593), saying that Paris and the peace of France were "worth a mass." At the same time, however, he secured to his former associates, then numbering about 760 congregations throughout the kingdom, in spite of the remonstrance of the pope and the bishops, a legal existence and the right of the free exercise of religion, by the celebrated edict of Nantes in 1598, which closes the stormy period of the French reformation. But the Reformed church in France, after flourishing for a time, was overwhelmed with new disasters under the despotism of Richelieu, and finally the revocation of the edict of Nantes by Louis XIV. in 1685 reduced it to a "church of the desert;" yet it survived the most cruel persecutions at home, and enriched by thousands of exiles the population of every Protestant country in Europe and America. IV. THE REFORMATION IN THE NETHERLANDS was kindled partly by Lutheran influences from Germany, but mostly by Reformed and Calvinistic influences from Switzerland and France. Its first martyrs, Esch and Voes, were burned at Antwerp in 1523. The despotic arm of Charles V. and his son Philip II. resorted to the severest measures for crushing the rising spirit of religious and political liberty. The duke of Alba surpassed the persecuting heathen emperors of Rome in cruelty, and, according to Grotius, destroyed the lives of 100,000 Dutch Protestants during the six years of his regency (1567-'73). Finally the seven northern provinces formed a federal republic, first under the leadership of William of Orange, and after his assassination (1584) under his son Maurice, and after a long and heroic struggle accomplished their severance from the church of Rome and the Spanish crown. The southern provinces remained Roman Catholic and subject to Spain. The first Dutch Reformed synod was held at Dort in 1574, and in the next year the university of Leyden was founded. The Protestant-

ism of Holland is predominantly Calvinistic, and adopts as its doctrinal and disciplinary standards the Heidelberg catechism as published (in Latin and German) in 1563, the Belgic confession of 1561, and the articles of the synod of Dort of 1618-'19. This important synod was held in consequence of the Arminian controversy, which violently agitated the country at that time. The Arminians or Remonstrants, differing in five points from the Calvinists, and holding to the freedom of the will and a conditional predestination, were condemned by the synod of Dort, but continued as a tolerated sect, and exerted, through the writings of their distinguished scholars and divines, Arminius, Hugo Grotius, Episcopius, Limborch, and Le Clerc (Clericus), considerable influence upon Protestant theology in England, France, and Germany during the 18th century. The orthodox church of Holland has been represented in the United States since 1609 by the Reformed Protestant Dutch church (now the "Reformed church in America"), the oldest save one of the denominations in the United States. V. THE REFORMATION IN HUNGARY. This country was first brought into contact with the reform movement by disciples of Luther and Melancthon, who had studied at Wittenberg, after 1524. Ferdinand I. granted to some magnates and cities liberty of worship, and Maximilian II. (1564-'76) increased it. The synod of Erdöd in 1545 organized the Lutheran, and the synod of Osenger in 1557 the Reformed church. The German settlers mostly adopted the Augsburg confession, the national Magyars the Helvetic. Rudolph II. having suppressed religious liberty, Prince Stephen Bocskay of Transylvania, strengthened by his alliance with the Turks, reconquered by force of arms (1606) full toleration for the Lutherans and Calvinists in Hungary and Transylvania, which, under his successors Bethlen Gábor and George Rákóczy I., was confirmed by the treaties of Nikolsburg (1622) and Linz (1645). In Transylvania Socinianism also found a refuge, and has maintained itself to this day. VI. THE REFORMATION IN POLAND. Fugitive Bohemian Brethren or Hussites and the writings of the German reformers started the movement in Poland. King Sigismund Augustus (1548-'72) favored it and corresponded with Calvin. The most distinguished Protestant of that country was Jan Laski, or John à Lasco, a Calvinist, who fled from Poland for his faith, was called back by the Protestant nobility, aided by several friends translated the Bible, and labored for the union of the Reformed and Lutherans (died 1560). A compromise between the two parties was effected by the general synod of Sandomir (*Consensus Sandomiriensis*) in 1570; but subsequently internal dissensions, the increase of Socinianism, and the efforts of the Jesuits greatly interfered with the prosperity of Protestantism in that country. The German provinces now belonging to Russia,

Courland, Livonia, and Esthonia, opened likewise the door to the reformation, and adopted the Augsburg confession. VII. THE REFORMATION IN SCANDINAVIA. The reformers of Sweden were two brothers, Olaf and Lars Peterson, or Petri, disciples of Luther, who after 1519 preached against the existing state of the church. Gustavus Vasa, who delivered the country from the Danes and became king in 1523, favored Protestantism from political and mercenary motives; the whole country, including the bishops, followed without much difficulty. He appropriated a large portion of the wealth of the church to meet the expenses of his wars and administration. The synod of Örebro in 1529 sanctioned the reform, and the synod of Upsal in 1593, after a fruitless attempt to reconcile the country to Rome, confirmed and completed it. Sweden adopted the Lutheran creed, to the exclusion of every other, and retained the episcopal form of government in the closest union with the state. It did great service to the cause of Protestantism in Europe, through its gallant king Gustavus Adolphus, in the thirty years' war; and recently the intolerant laws against dissenters have been almost completely abolished. Denmark became likewise an exclusively Lutheran country, with an episcopal form of state-church government, under Christian III. A diet at Copenhagen in 1536 destroyed the political power of the Roman clergy, and divided most of the church's property between the crown and the nobility. The remaining third was devoted to the new ecclesiastical organization. Bugenhagen of Wittenberg was then called to complete the reform. From Denmark the reformation passed over to Norway about 1536. The archbishop of Drontheim fled with the treasures of the church to Holland; another bishop resigned; a third was imprisoned; and the lower clergy were left the choice between exile and submission to the new order of things, which most of them preferred. Iceland, then subject to Danish rule, likewise submitted to the Danish reform. VIII. THE REFORMATION IN ENGLAND. The struggle between the old and the new religion lasted longer and raged more fearfully in England and Scotland than on the continent, and continued in successive shocks even down to the end of the 17th century, for Puritanism was a second reformation; but it left in the end a very strong impression upon the character of the nation, and affected deeply its political and social institutions. In theology English Protestantism was dependent upon the continental reform, especially the ideas and principles of Calvin; but it displayed greater practical energy and power of organization. It was from the start a political as well as a religious movement, and hence it afforded a wider scope to the corrupting influence of selfish ambition and violent passion than the reformation in Germany and Switzerland; but it passed also through severer trials and persecutions. In

the English reformation we distinguish five periods. The first, from 1527 to 1547, witnessed the abolition of the authority of the Roman papacy under Henry VIII. This was merely a negative and destructive process, which removed the outward obstruction and prepared the way for the reform. Henry VIII. quarrelled with the pope on purely personal and selfish grounds, because the pope properly refused consent to his divorce from Catharine of Aragon and his marriage to Anne Boleyn. "The defender of the faith," a title given him by the pope for the defence of the seven sacraments against Luther, remained in doctrine and religious sentiment a Roman Catholic to the end of his life; and at his death the so-called "bloody articles," which enjoined under the severest penalties the dogma of transubstantiation, auricular confession, private masses, and the celibacy of the priesthood, were yet in full force. The only point of radical difference was the royal supremacy. He simply substituted a domestic for the foreign, and a political for an ecclesiastical papacy, and punished with equal severity Protestant as well as Roman Catholic dissenters who dared to doubt his supreme headship of the church of England. But while he thus destroyed the power of the pope and of monasticism in England, a far deeper and more important movement went on among the people under the influence of the revived traditions of Wycliffe and the Lollards, the writings of the continental reformers, and the English version of the Scriptures commenced by Tyndale, carried on by Coverdale and Rogers, and revised by Cranmer. The second period embraces the reign of Edward VI., from 1547 to 1553, and contains the positive introduction of the reformation by the coöperation mainly of the duke of Somerset, protector and regent during the king's minority, and Cranmer, archbishop of Canterbury, who by his pliable conduct and subserviency to the will of Henry had preserved the idea and hope of a reformation through that reign of terror. Cranmer was assisted in the work by Ridley and Latimer, and by several Reformed divines from the continent whom he called to England, especially Martin Bucer of Strasburg, now elected professor at Cambridge, and Peter Martyr of Zürich (originally from Italy), for some time professor at Oxford. The most important works of this period, and in fact of the whole English reformation, next to the English version of the Bible, are the 42 articles of religion (subsequently reduced to 39), or a new and moderately Calvinistic confession of faith, and the "Book of Common Prayer," or a new directory of worship in the vernacular tongue, on the basis of the old Latin service, but with essential changes. The third period is the reign of Queen Mary, from 1553 to 1558, and presents to us the unsuccessful attempt of that queen and her friend Cardinal Pole, now made archbishop of Canterbury after the deposition

of Cranmer, to undo the reformation and to restore the Roman Catholic religion and the authority of the pope. This Catholic interim did more to consolidate the reformation in England than Henry, Edward, and Elizabeth. Hundreds were martyred in this short reign; among them the three British reformers, Ridley, Latimer, and Cranmer, who were publicly burned at Oxford in 1555 and 1556. Many others fled to the continent, especially to Geneva, Zürich, Basel, and Frankfort, where they were hospitably received and brought into closer contact with the Reformed churches of Switzerland and Germany. The fourth period is the restoration and permanent establishment of the Anglican reformation during the long reign of Elizabeth, 1558 to 1603. The Roman Catholic hierarchy was replaced by a Protestant, and the articles of religion and the common prayer book of the reign of Edward were introduced again, after a revision. The ecclesiastical supremacy of the crown was likewise renewed, but under a modified form, the queen refusing the title "supreme head" of the church of England, and choosing in its place the less objectionable title "supreme governor." The convocation and parliament readily sanctioned all these changes; but the Anglican church as established by Elizabeth was semi-Catholic in its form of prelatical government and liturgical worship, a sort of *via media* between Rome and Geneva. It suited the policy of the court and the taste of the majority of the English people, but was offensive to the severer school of strict Calvinists who had returned from their continental exile. Hence the agitation in the bosom of the reformed church of England, and the growing conflict between the Episcopalian majority and the puritanic minority. Elizabeth's reign was as intolerant against Puritan as against papal dissenters, and passed the severest penal laws against both. But while the Catholic party was almost annihilated in England, the Puritan party grew more powerful under the successors of Elizabeth, and overthrew the dynasty of the Stuarts, and even the Episcopalian establishment, although the latter revived from the shock. These troubles and agitations constitute the fifth period in the history of English Protestantism, which in some respects is the most important and interesting, but lies beyond the age of the reformation proper.

IX. THE REFORMATION IN SCOTLAND. The first impulse to the reformation in Scotland proceeded from Germany and Switzerland. Copies of the writings of the continental reformers and of Tyndale's English Testament found their way to the far north. The first preacher and martyr of Protestantism in that country was Patrick Hamilton, a youth of royal blood, and for some time a student at Wittenberg and Marburg, who was condemned to death by Archbishop Beaton and burned at the stake. The movement gradually increased in spite of persecution, especially after the rup-

ture of England with the pope, and was carried to a successful conclusion under the guidance of John Knox. He was a disciple and admirer of John Calvin, with whom he spent several years. He returned after the accession of Elizabeth to his native country, resolved to reform the Scotch church after the model of the church of Geneva. After a short civil war the parliament of 1560 introduced the reformation, and adopted a Calvinistic confession of faith, drawn up by Knox, Spottswood, Row, and others (superseded afterward by the Westminster standards), and prohibited under severe penalties the exercise of the Roman Catholic worship. In 1561 the first "Book of Discipline" was issued, and gave the new church a complete presbyterian organization, culminating in a general assembly of ministers and elders. The mode of worship was reduced to the greatest simplicity, with a decided predominance of the didactic element. When the unfortunate Mary Stuart, of French education, tastes, and manners, and in no sympathy with the public opinion of Scotland, began her reign in August, 1561, she made an attempt to restore the Roman Catholic religion, to which she was sincerely devoted. But her own imprudences and the determined resistance of the nation frustrated her plans, and after her flight to England (1568) Protestantism was again declared the only religion of Scotland, and received formal legal sanction under the regency of Murray.—Among the numerous historians of the reformation, in whole or in part, the following deserve special mention: Sleidan, *De Statu Religionis et Reipublicæ Carolo V. Casare* (Strasburg, 1555); Beza, *L'Histoire ecclésiastique des églises réformées au royaume de France*, &c. (3 vols., Lille, 1580); Burnet, "Reformation in England" (3 vols. fol., London, 1679-1714); Seckendorf, *Commentarius Historicus et Apologeticus de Lutheranism* (3 vols. fol., Leipsic, 1686-'92); Strype, "Annals of the Reformation" (4 vols. fol., London, 1709-'31), and "Ecclesiastical Memorials" (3 vols. fol., 1721), and his lives of Cranmer, Parker, Knox, McCrie, Hetherington, and others; Schröckh, *Christliche Kirchengeschichte seit der Reformation* (10 vols., Leipsic, 1804-'12); Marheineke, *Geschichte der deutschen Reformation* (4 vols., Berlin, 1816-'34); Hottinger, *Geschichte der schweizerischen Kirchentrennung* (2 vols., Zürich, 1825-'7); Ruchat, *Histoire de la réformation de la Suisse* (6 vols., Geneva, 1727); Merle d'Aubigné, *Histoire de la réformation au XVI^e siècle* (5 vols., Paris, 1835-'53), and *Histoire de la réformation au temps de Calvin* (5 vols., 1862-'8; vol. vi., 1875), both works translated into English; the English translation of vol. iv. of Gieseler's *Lehrbuch der Kirchengeschichte* (New York, 1858), valuable for its extracts from original authorities; L. Haüsser, *Geschichte des Zeitalters der Reformation* (Berlin, 1868; English translation, 1874); and George P. Fisher, "History of the Reformation" (New York, 1873).

REFORMATORIES, institutions for the reformation of juvenile offenders, and for the care and correctional education of neglected children. This duty, but recently assumed by the government in most countries, was previously left to the philanthropic efforts of individuals. The oldest and the largest reformatory in the United States is the house of refuge on Randall's island, New York city, which was opened in 1825. (See *New York*, vol. xii., p. 397.) The Boston house of refuge was opened in 1827, that in Philadelphia in 1828, and that in New Orleans in 1847. But these, though supported in whole or in part by grants from the public revenue, were not managed directly by the state. The importance of making juvenile reformatories a part of the public penal system was recognized by Massachusetts in 1848, when the state reform school at Westborough was established. Similar institutions were organized by other states, so that in 1873 not less than 34 reformatories for juvenile offenders were maintained and managed by the states, or largely aided by them, as follows:

NAME OF INSTITUTION.	Where situated.	When opened.	Average number of inmates during the year.
City and county industrial school.....	San Francisco, Cal.....	1858	456
State reform school.....	West Meriden, Conn..	1854	316
Industrial school for girls.....	Middletown, Conn....	1870	75
State reform school....	Pontiac, Ill.....	1871	175
House of refuge.....	Plainfield, Ind.....	1868	200
Reformatory institution (for women and girls).....	Indianapolis, Ind.....	1873	44
State ref. school, boys.....	Eldorado, Iowa.....	1868	145
State ref. school, girls.....	Salem, Iowa.....	1868	11
House of refuge.....	Louisville, Ky.....	1865	161
House of refuge.....	New Orleans, La.....	1847	109
State reform school....	Portland, Me.....	1852	184
House of refuge.....	Baltimore, Md.....	1855	286
House of reformation.....	Rosaryville, Md.....	1873	60
Boston house of reformation.....	Deer Island, Mass....	1827	301
State industrial school for girls.....	Lancaster, Mass.....	1856	121
State reform school....	Westborough, Mass..	1848	289
State reform school....	Lansing, Mich.....	1856	211
House of refuge.....	St. Louis, Mo.....	1854	92
State reform school....	Manchester, N. H.....	1855	101
State reform school....	Jamesburg, N. J.....	1867	153
State industrial school for girls.....	Trenton, N. J.....	1871	25
House of refuge.....	Randall's Island, N. Y.	1825	555
Juvenile asylum.....	New York, N. Y.....	1851	617
Catholic protectory....	West Chester, N. Y....	1863	1,629
Western house of refuge.....	Rochester, N. Y.....	1849	382
Girls' industrial home.....	Lewis Centre, Ohio....	1869	131
House of refuge.....	Cincinnati, Ohio.....	1851	207
Reform farm school....	Lancaster, Ohio.....	1857	430
House of refuge (white department).....	Philadelphia, Pa.....	1828	445
House of refuge (colored department)....	Philadelphia, Pa.....	1850	126
Pennsylvania reform school.....	Allegheny, Pa.....	1854	264
Providence reform school.....	Providence, R. I.....	1850	202
State reform school....	Waterbury, Vt.....	1866	127
Industrial school for boys.....	Waukesha, Wis.....	1860	271
Reform school.....	Washington, D. C....	1870	103

In all, about 100,000 boys and girls have been committed to these institutions. The time of sentence is generally during minority, though in a few states it is for a specified period. The boys and girls are required to learn trades, and to receive secular and religious instruction. The average number of inmates in 1873 was 8,924, of whom 7,743 were boys and 1,481 girls; the average cost of maintaining each inmate in 1872 was \$152; the average earnings of each were \$37; average stay in the institution, 1 year and 11 months for the boys and 3 years and 4½ months for the girls; considered reformed, 73 per cent. of those discharged. Where necessary, those discharged are provided with homes or employment, or indentured; and in some cases they are liberated on probation. Fifteen per cent. of those detained in 1873 had been vagrants, and 39 per cent. truants.—The reformatory system of Great Britain has been under the control of the government for but a comparatively brief period. The work of reforming juvenile delinquents was begun as early as 1788 by the philanthropic society, which founded the first English reform school near London. Similar institutions were established in London and elsewhere; that in Warwickshire, opened in 1818, was the first in which farm and outdoor labor was made a part of the training of the inmates. In 1838 an act was passed for the establishment of a separate prison at Parkhurst, Isle of Wight, for offenders under the age of 16 years. The discipline here was intended to be specially educational and reformatory. The greatest reformatory in England is that established at Redhill, Surrey, under the direction of Sidney Turner. It was modelled after the famous colony of Mettray in France, and is conducted on the principles of domestic management, absence of walls and wardens, and outdoor labor. Similar institutions were soon afterward opened at Hardwicke in Gloucestershire, near Birmingham, at Bristol, and in Hampshire. In 1854 the secretary of state was empowered to license reformatory schools in Great Britain approved by him, and to make an allowance for the maintenance of the young offenders committed to them. Certain courts and magistrates were authorized to commit to such institutions juveniles under 16 years of age for not less than two nor more than five years. At the same time provision was made for the establishment of industrial schools in Scotland for destitute and vagrant children under 14 years of age. An industrial schools act was passed for England in 1857, and in 1861 industrial schools in both England and Scotland were placed under the home office, with provision for an allowance from the treasury for their maintenance, similar to that given to reformatory schools. Reformatories are intended for correction, and industrial schools for prevention. Only those boys and girls are sent to a reformatory who have been convicted of some offence punish-

able by imprisonment or penal servitude, and who have been committed to jail in the first instance for not less than 10 days; they must be between 10 and 16 years of age, unless previously convicted or sentenced by a superior court. Industrial schools are for destitute and vagrant children under 14 years of age; they are sent directly to the institution, and do not pass through the jail. Children under 12 years of age, guilty of any petty offence, may also be sent to them instead of being committed to prison and a reformatory. Reformatories or industrial schools may be established in connection with any religious organization. The number of reformatories in Great Britain on Jan. 1, 1873, was 65, of which 45 were for boys and 20 for girls. The total number of inmates at that date comprised 4,424 boys and 1,151 girls. The number of certified industrial schools was 100, in which were 7,598 boys and 2,587 girls, besides 720 children who were under detention.—In France the establishments for the correctional education of juvenile delinquents receive boys and girls 16 years of age and under. The penitentiary colonies and correctional colonies are for boys. To the former are sent: 1, children acquitted as having acted without knowledge, but who are not sent back to their parents; 2, young prisoners sentenced for more than six months and not exceeding two years. Some of these are public institutions, founded and directed by the state; others have been established and are managed by individuals with the authorization of the government. The correctional colonies, which are all public, receive young prisoners sentenced for more than two years, and those from the penitentiary colonies who have been declared insubordinate. A similar classification is made for girls, for whom there are 20 establishments, of which one is directed by the state. There are 82 establishments for boys, including 3 public colonies, 4 correctional wards, and 25 private colonies. The most successful of the French reformatories for boys is the agricultural colony at Mettray, five miles from Tours. (See METTRAY.) The principles of family groups and agricultural labor were copied from the Rauhes Haus, near Hamburg, which was established by Dr. Wichern in 1833, and has long been one of the most noted institutions of the kind in Europe.—Belgium has a highly successful institution for the reformation of juveniles, not criminals, but vagrants, truants, street beggars, &c. It comprises three different schools, two for boys and one for girls; the former are at Ruysselede and Wynghene, within sight of each other, and the latter is at Beernem, two or three miles distant. The chief occupation of the boys is farm work, though during the winter they are employed in a variety of trades. The girls are engaged chiefly in lace making, sewing, and laundry work. This institution is noted for the class of neglected children it is intended for, and is self-sustaining.

REFORMED CHURCH. The Protestants on the continent of Europe were divided, about the middle of the 16th century, into two main bodies, known as the Lutheran church and the Reformed church. Though these designations are insufficient to include all the subsequent divisions and sects, yet they mark two distinct types of theology and polity, which have been ever since perpetuated. The so-called Reformed churches are those nurtured under the influence of what is popularly known as the Calvinistic system. This system is contrasted with Lutheranism in several marked particulars. Its keynote is in the doctrine of the divine sovereignty, held not as a philosophical speculation, but as a religious tenet. Luther indeed agreed with Calvin, using even stronger forms of statement, as to the servitude of the fallen human will, and the doctrine of election. But the Lutheran theology, under Melancthon's influence, and in the *Formula Concordiæ*, renounced the decree of unconditional election; nor did its divines defend the supralapsarian scheme. Another theological difference was upon the theory of the Lord's supper. Luther, though denying transubstantiation, affirmed a supernatural union of the body and blood of Christ with the consecrated elements, and advocated a literal interpretation of the words, "This is my body," holding to the real presence of Christ in the eucharist, in such a sense that the communicant, worthy or unworthy, actually receives the body of Christ into the mouth, "in, with, and under the form of the bread." The Lutheran divines asserted the ubiquity, though not in the common sense, of Christ's body, resulting from the union of the divine and human natures in his person. Calvin, on the contrary, maintained the real presence of Christ in the supper only in a spiritual sense, and a spiritual reception on the part of the communicant, the body of Christ meanwhile remaining in heaven, and imparting its virtue by a wonderful spiritual process. (See Julius Müller, *Lutheri et Calvini Sententiæ de Sacra Cœna inter se comparatæ*, Halle, 1858.) But in contrast with Zwingli, Calvin held that the sacraments were seals and pledges, and not merely signs, of divine grace. Montesquieu says that the Lutheran and Reformed communions each believed itself to be most perfect: "The Calvinists believe themselves to be most conformed to what Jesus has said, the Lutherans to what the apostles have done." "The Calvinists," says Schweizer, "contended against the paganism of Rome, and the Lutherans against its Judaism." The latter have been more practical, the former more speculative; the one communion most absorbed in the reconciliation of sovereignty with free will, the other most devoted to the problem of the relation of the divine to the human, especially in the person of Christ. The Lutheran paid more deference to tradition, the Calvinist relied more on the exclusive authority of Scripture, often not distin-

guishing between the Old and New Testaments. Both adopted the presbyterian polity; but the Lutherans insisted more on the territorial rights of princes, while the Reformed emphasized the rights of the people.—The Reformed movement began in Switzerland, under the lead of Zwingli, the hero of Zürich, as early as 1516; in Basel it was headed by Ecolampadius; Geneva was aroused by the intrepid Farel, and taught and organized by Calvin, who came thither, a refugee from France, in 1536. Switzerland was revolutionized by a grand popular movement. The same form of faith was planted in the Palatinate, where was formed the German Reformed church, under the elector Frederick III., combining the spirit of Melancthon with that of Calvin. It was accepted in Bremen, 1561-'81; in Nassau, 1582; in Anhalt, 1596; in Hesse-Cassel, 1605; and even the elector of Brandenburg, John Sigismund, adopted it in 1614. Its churches were also scattered in Bohemia, Hungary, and Poland. The first reforms in Spain and Italy, soon suppressed, were nourished in part under its teachings. In France it attained such vigor that in 1559 a general synod was formed at Paris, and its churches numbered about 2,000. But here they were decimated by religious wars, and by the massacre of St. Bartholomew's, 1572, and enfeebled by the abjuration of Protestantism by Henry IV. The revocation of the edict of Nantes, Oct. 22, 1685, deprived 2,000,000 French Protestants of their religious security, and drove out half a million into all parts of Europe and America before the close of the century. The Reformed system was also introduced into Holland, where the reformation found martyrs as early as 1523. The fierce struggle of the United Netherlands with Philip II. of Spain (1555-'98) was both for civil and religious freedom. The peace of Westphalia in 1648 confirmed the rights and liberties of the Dutch church. In England the reformation at first advanced more slowly. Crammer gave it shape, mainly in the sense of the Reformed symbols, under Edward VI. The persecutions under Mary sent the most ardent of England's reformers to Zürich and Geneva, whence they brought back the seeds of Puritanism. But the Anglican church, though allied to the Reformed faith in its articles of religion, retained the episcopate, and in its prayer book taught the elements of the sacramental system. The act of uniformity (1559) led to a strong Puritan resistance; and the conflict passed over into the 17th century, coming to its height in the civil war of 1642-'9, and the beheading of Laud and of King Charles. But the success under Cromwell was of short duration; and the strength of the Reformed influence was removed from England to America. In Scotland it was firmly established under Knox's influence after his return from the continent in 1559, and organized by the "Solemn League

and Covenant;" and this land has never swerved from its loyalty to the faith of Geneva. In the form of Congregationalism, the same system of faith was transplanted to the new world by the pilgrims who landed on Plymouth rock, and by large subsequent immigrations; in the form of Presbyterianism (including the German and Dutch Reformed churches), it was established in the middle and southern colonies by emigrants from Scotland, Ireland, England, and Holland; and at no period since has it ceased to exert a strong and vital influence upon the principles and history of this country. The Baptist churches of England and America adopt in the main the same system of faith. In other parts of the world, by colonization and emigration, the Reformed church is also widely diffused.—In correspondence and harmony with this wide geographical diffusion, the Reformed church has also shown great productive power in respect to confessions of faith and systems of theology, which, while retaining the same essential features, have set forth different types of doctrine. In this respect it is distinguished from the Roman Catholic and the (orthodox) Lutheran communions. At the very beginning of the Reformed movement we find Zwingli and Calvin differing in their modes of expounding the common faith, the former resolving original sin into a natural defect, and cultivating theology more in the spirit of the man of letters. Even in Switzerland, besides the stricter traditional and scholastic method, exemplified by Heidegger, and brought to its consummation in Turretin, Stapfer also taught, in his able "Polemics," the mediate and not exclusively immediate imputation of Adam's sin. The famous school of Saumur in France, under the impulse of the Scotchman Cameron and the guidance of Amyraut, abandoned the dogma of a limited atonement in favor of the scheme of a hypothetical universalism of divine grace. But the most fruitful seminary of these Calvinistic systems in the 17th century was Holland. Its divines were at first divided between the supralapsarian and the infralapsarian schemes. The great Arminian controversy led to the convocation of the synod of Dort, 1618-'19, at which representatives attended from the English church as well as from other reformed communions; and where, against the Remonstrants, the five points of Calvinism were articulately defined, viz.: 1, unconditional election; 2, particular redemption; 3, total depravity; 4, grace irresistible; 5, the perseverance of the saints. Three prominent types of theology were represented in the subsequent religious development in the Netherlands: 1, the scholastic, advocated by Maresius, Wendelin, Gomarus, and Voetius; 2, the federal theology, or the theology which takes the idea of covenants as its central conception, which received its fullest exposition in the works of Cocceius and Witsius, modifying the rigidity of the scholastic formulas by

a more Biblical and historical method; and 3, the Cartesian type, which made use of the principles of the philosophy of Descartes to expound and vindicate the Christian system, and rendered good service in giving a more systematic form to natural theology as the logical basis of revealed theology, and in the attempt to harmonize the rights of reason with the demands of faith. The Reformed theology of the Palatinate found its best expression in the Heidelberg catechism (1563) drawn up by Ursinus and Olevianus, and adopted as a symbol by the German Reformed and Dutch churches. In England, Scotland, and America this system of faith is expressed in the Westminster confession of faith and catechisms, adopted by the long parliament in 1646, by the kirk of Scotland in 1647, by the Cambridge synod of New England in 1648, and by the Presbyterian church of America in 1729. The subsequent divisions in the Scotch church were chiefly upon the question of the relation of the church to the civil power (Associate presbytery, 1733; Covenanters, 1743; Burghers and Anti-Burghers, 1747; Relief Secession, 1761). In the "marrow controversy" (Fisher's "Marrow of Modern Divinity") five propositions were condemned in 1720, which were supposed to have an Antinomian tendency. The Scottish orthodoxy was upheld in the last half of the 18th century by Erskine, Hill, and others; though somewhat enfeebled by the lukewarmness of the Robertson administration, 1758-'82. It has been revived in the present century, chiefly through the zealous advocacy of Chalmers. In the Anglican church there have always remained some able advocates of the fundamental principles of the Reformed system, as Davenant, Leighton, Ezekiel Hopkins, and John Edwards; but it has chiefly flourished among the nonconformists of England, represented by such men as Thomas Watson, Baxter, Owen, Howe, Ridgeley, Matthew Henry, and Isaac Watts, not to name men of later date. In the writings of Tobias Crisp it is Antinomian in its tendency.—Nearly contemporaneous with the decline of the Calvinistic system in its productive vigor upon the continent of Europe, was the rise of its most elaborate and philosophical defender in our own land, in the person of the elder Edwards. (See EDWARDS, JONATHAN.) He stands at the head of a school, that of the so-called New England theology, which may well vie with any European type of this system in ingenuity, comprehensiveness, and moral vigor. Denying a limited atonement, insisting upon the distinction between natural ability and moral inability, making the essence of virtue to consist in holy love, and opposing the dogma of immediate imputation, it has exerted a prevailing influence upon the tone of theological speculation, and borne permanent fruits in the writings of Bellamy, Hopkins, Smalley, the younger Edwards, and Emmons. The later representatives of the Reformed dogmatics upon the continent of Eu-

rope, as Schleiermacher, Ebrard, Schneckerburger, Schweizer, and Vinet, have advocated it in a historical and philosophical, rather than a traditional and scholastic spirit.—In estimating the influence of this system, we ought not to pass unnoticed the fact that a large portion of the denominations and sects of modern Christendom have sprung into being from its impulse, or in opposition to it. This was the case with the Arminians; in part also with the Unitarians of Poland, Transylvania, England, and New England; with the Baptists in their various ramifications; and with the Wesleyans or Methodists of England and America. The Reformed church has been fruitful in sects. The Lutheran church of Europe has always been under bonds to the state; the Reformed churches have more frequently claimed their own rights, and demanded a relative independence. The presbyterian polity was essentially a representative system; its lay elders (chosen for life in Scotland and Geneva, and for a limited period in Holland, France, and Germany) gave it vitality. Its presbyterial and synodal constitution, aristocratic in France and Geneva, and more democratic in Holland and Scotland, has made it efficient. It has also been zealous in administering discipline. The power of the laity was still further enhanced in the congregational or independent form of polity, so largely adopted in England by the nonconformists, including the Baptists, and prevalent in New England. Thus fitted to be a working church, it has in most of its branches been zealous in domestic and foreign missions, and has led the way to the progressive reforms that characterize modern society.

REFORMED (DUTCH) CHURCH IN AMERICA (formerly REFORMED PROTESTANT DUTCH CHURCH), a religious body which arose in the Netherlands early in the 16th century, and attained its form and organization during the struggle against Philip II. under the leadership of the princes of Orange. For a long time those who embraced the evangelical doctrines could worship only with the utmost privacy, and they denominated their assemblies "the churches of the Netherlands under the cross." In 1561 a confession of faith was published by Guido de Bres, called the Belgic confession, modelled after that of the Calvinistic church of France. It was adopted by the first synod held in 1568 at Wesel on the Rhine. Public field preaching was introduced about the same time, and also singing in the native language. Churches were formed after the Genevan presbyterian model, and at the synod of Wesel rules of church order were adopted, and the scattered churches were organized as one body. Soon afterward the yoke of Spain was formally thrown off by the provinces, and the Protestant faith became the religion of the state. In the early part of the 17th century the famous Arminian controversy distracted the church. Arminius, professor of theology in the university of Leyden, advanced sentiments which

were thought by his colleague Gomarus to be at variance with the standards of the church. A controversy arose, in which ministers and church members throughout the country took sides, the larger portion by far sympathizing with the Gomarists, while those who were high in political power for the most part favored the Arminians. In a remonstrance to the states, the views of the Arminians on the famous five points of predestination, redemption, depravity, conversion, and perseverance were defined. From this paper they were called Remonstrants, and their opponents were from their reply called Contra-Remonstrants. The Contra-Remonstrants urged the call of a national synod to decide on the new opinions, and the Remonstrants opposed it. The former contended for the independence of the church in matters of discipline; the latter deferred much to the authority of the civil government. At length, after a protracted controversy under the stadtholder Maurice, a national synod met at Dort in 1618, and continued in session six months. By it the doctrines of the Remonstrants were condemned, and those who had taught them were deposed from the ministry and deprived of all ecclesiastical and academical offices. The decision of the synod was followed by the action of the states forbidding all assemblies of the Remonstrants, and banishing many of the deposed ministers. The Remonstrants were afterward tolerated, and have continued as a small sect in the Netherlands, while their doctrines have spread widely into other countries. By this last national synod of the church in the Netherlands her doctrines and order were finally settled. Through the remainder of the century she was greatly prospered, was zealously carried into all the Dutch colonies east and west, and was known especially for her tolerant spirit. The church and republic of the Netherlands furnished an asylum for the oppressed of every creed and nation. Of late, however, the ministers and members of the national church have to a great extent departed from the evangelical doctrines of the standards, and rationalistic and Socinian ideas greatly prevail among them.—The church was introduced into America early in the 17th century. The first permanent agricultural settlement in New Netherland was made in 1623, and soon the colonists enjoyed the services of two *krankbesoekers* or consolars of the sick, who were officers of the church, and whose duty it was to visit and pray with the sick, and conduct public worship in the absence of a minister. These read the Scriptures and creeds to the people assembled in an upper room over a horse mill. In 1628 the Rev. Jonas Michælius arrived at Manhattan, organized a consistory, administered the sacraments, and performed all the functions of the ministry. He was succeeded in 1633 by the Rev. Everardus Bogardus, who was accompanied by the first schoolmaster, Adam Roelandsen. Bogardus

married the widow Annetje Jansen, whose farm has now become the valuable property held by the corporation of Trinity church. In his time a plain wooden building was put up for worship in Broad street, between Pearl and Bridge. The second building was erected under the administration of Director Kieft in 1642, and stood within the walls of Fort Amsterdam on the Battery. After the surrender of New Amsterdam to the English in 1664, this church was used by the military chaplains when not occupied by the consistory; and after the Dutch people removed into their new edifice in Garden street, it was used by the English garrison for worship down to 1741. Public worship was commenced at Albany perhaps as early as at New Amsterdam, but the first minister there of whom we have knowledge was Johannes Megapolensis, who soon after his arrival in 1643 preached the gospel to the Indians who came to Fort Orange to trade. During the Dutch rule churches were also established at Esopus (Kingston, N. Y.), Flatbush and Flatlands, and Brooklyn. New Amsterdam at the time of its surrender contained only about 1,500 inhabitants, and in the entire province of New Netherland there were five churches and six ministers. From that time until recently the progress of the church in America has been necessarily slow, for the following reasons: 1. The emigration from the Netherlands almost entirely ceased, and many families, willing to live only under their native government, returned to the Netherlands. 2. Government patronage was removed on the transfer of the province to the British and the introduction of the English church, to which church also advantages were given amounting to its virtual establishment by law in New York, Westchester, Queens, and Richmond. 3. The Dutch language was used exclusively in worship down to the year 1763; consequently the church could not gather within her fold those who used another language, nor extend herself to new settlements. Meanwhile the English language was used in schools and in public business, and had at last become the prevailing and popular tongue. Although English preaching was introduced in 1763, the Dutch continued to be the prevailing language in the various pulpits down to the present century, but after that it rapidly gave way to the English, and now is no more heard in public worship, save in the churches composed of recent emigrants from Holland. The minutes of the general synod began to be kept in English in 1794. 4. The church suffered from a deficiency of ministers, and the obstacles that were in the way of obtaining a supply. She had no educational institutions, and no church judicatory with power of ordination; her ministers all belonged to the classis of Amsterdam, and to that classis she applied for ministers, and to it she sent her candidates to receive ordination. By these means the congregations were often subjected

to great delay and expense. Then arose the noted *coetus* and *conferentie* controversy. The *coetus* was a body formed in 1747, which possessed no ecclesiastical, but only advisory powers. From this sprang the *coetus* party, who proposed that this assembly should be changed into a regular classis, that an educational institution should be established, and that the church should thus boldly undertake to supply herself with a ministry. This was opposed by the *conferentie*, who zealously advocated a continuance of the state of dependence on Holland. At last, through the agency of the Rev. John H. Livingston, D. D., the breach was healed, and in 1771 an independent church organization was effected. A convention of ministers and elders met in New York in October of that year, by which three objects were secured: 1, the internal arrangement and government of the churches, embracing the organization of superior church judicatories and measures for the establishment of a professorship of theology; 2, healing of dissensions; 3, correspondence with the church in Holland. The acts of the convention were soon followed by the approbation, good wishes, and prayers of the classis of Amsterdam. The church in Holland made it an express condition of the independence of the church in America that she should at once initiate measures for the training of a learned ministry. The classis of Amsterdam was therefore petitioned to send over a professor of theology, but instead of this they recommended the appointment of Dr. Livingston. On account of the breaking out of the revolutionary war, his appointment was delayed till 1784. During the war the congregations in New York were scattered, the houses of worship desecrated, and of the four pastors, three never returned to their field of labor. The church now completed her organization by the formation of a general synod, which at first met triennially, but after 1812 annually. A constitution, compiled by Drs. Livingston and Romeyn from the acts of the synod of Dort, and adapted to the church in this country, was adopted. In 1770, through efforts of the *coetus* party, a charter had been obtained for a college, to be called Queen's, which was established at New Brunswick, N. J. A chief object of this college was, as its charter declares, to prepare young men for the ministry of the Reformed Dutch church, and it was required that its president should be a member of that church. From fear of awakening old prejudices, the professorship of theology was kept separate from the college till 1810, when Dr. Livingston removed to New Brunswick, and in addition to his professorship held the office of president of Queen's college. In 1825 the college, whose exercises had for some years been suspended, was revived under the name of Rutgers, and a new covenant was framed between the synod and board of trustees. (See **NEW BRUNSWICK, and RUTGERS COLLEGE.**)—Members of the Dutch church coöperated in

1793 with many from other churches in forming the New York missionary society. Ministers were also sent on missionary tours to Kentucky and Canada, and some churches were established, but by reason of distance and inherent weakness they were soon lost. The efforts at extension were afterward mainly directed to western New York, and about the year 1830, when the present board of domestic missions was organized, a number of important posts were occupied. In 1836 missions to the western states were commenced. At present there are 76 churches in the western states, of which a large number are composed of emigrants from Holland. There are no churches in New England, and none south of Philadelphia. Five sixths of the churches are in the states of New York and New Jersey. Two thirds of all the churches in the connection have been organized within the past 50 years, and during that time the ministry has increased more than fourfold. In 1817 the general synod coöperated with the Associate Reformed and Presbyterian churches in the formation of the united foreign missionary society, which in 1826 was merged in the American board of commissioners for foreign missions. In 1832 the synod made an arrangement with the American board, under which in 1836 a band of missionaries went forth from the Dutch church destined for the Dutch East Indies. Stations were begun on the island of Borneo, and soon a part of the band was sent to establish a mission at Amoy in China. On account of a diminution of the numbers of the missionaries and a lack of reinforcements, the stations in Borneo were after a few years abandoned. The missionaries at Amoy have been eminently successful. In southern India are several churches forming the classis of Arcot, which at first were ministered to by five sons of the Rev. Dr. John Seudder. The arrangement with the American board continued in force till 1857, when an amicable separation was effected, and the missions of Amoy and Arcot were transferred to the Reformed Dutch church. In 1859 missionaries were sent to Japan, where they have done an admirable work, especially in education. Mission work is also to a limited extent conducted among the Indian tribes in the far west. Besides the boards of domestic and foreign missions, the general synod established a board of Sabbath school union, which has since been abolished; a board of education for the aid of pious indigent young men in preparing for the ministry; a board of publication, which aims to spread a sound religious literature; a relief fund for the aid of disabled ministers and the families of deceased ones; and a fund for church extension.—In 1822 the Rev. Solomon Froeligh, D. D., of Hackensack and Schraalenburgh, N. J., and a few other ministers, seceded with their congregations from the Dutch church, on the alleged ground of a prevailing laxness in doctrine and discipline, and organized the "True

Reformed Dutch church." It has only a few congregations.—The doctrinal standards of the church are: 1, the Belgic confession of faith; 2, the Heidelberg catechism; 3, the canons of the synod of Dort. The Belgic confession of faith was published in 1561, and adopted as a standard by the synod of Wesel in 1568. This was the basis of the organization of the Reformed church in the Netherlands, and in its 37 articles presents a complete systematic view of the doctrines of the reformation. The Heidelberg catechism was received about the same time. It had been composed by order of the elector Frederick III. for the Palatinate, by Ursinus, a professor in the university of Heidelberg, and Olevianus, a court preacher. It was intended by the elector to be a harmonizing symbol of faith, to be received by both the Lutherans and Reformed in his dominions. The church in the Netherlands heartily adopted it, divided it into 52 Lord's days, and ordered that it should not only be taught to the youth, but expounded once in the course of every year from the pulpit. The canons were adopted by the synod of Dort in 1619, and framed with special reference to the five points of the Arminians which were condemned by that synod. In the church of the Netherlands, forms of prayer were at first used in ordinary public worship in connection with extemporaneous prayers. Such forms are now found in the liturgy of the Reformed church in America, but their use, though allowed, is not enjoined. Practically they are regarded as directories for the performance of that part of the service. There are other portions of the liturgy the use of which is made obligatory by the constitution, viz., forms for the administration of the sacraments, for the ordination and installation of ministers, elders, and deacons, and for the excommunication and readmission of members. This liturgy in its essential parts was composed for the church in London in 1551 by Jan Laski or John à Lasco, who used the labors of Calvin, Polanus, and others. This church in London was composed of Protestant refugees from Germany and the Netherlands, who in Britain under the reign of Edward VI. found an asylum from persecution. Driven back to the continent on the accession of Mary, they carried their liturgy with them. It was rearranged by Dathenus and adopted substantially by the synod of Wesel in 1568. It was afterward revised and confirmed by the synod of Dort. The English translation now in use in this country was first published by the consistory of the collegiate church of New York in 1767. In 1853 a movement was made for the revision and amendment of the liturgy. This subject was under consideration till 1858, when it was decided that no alterations should be made. The synod of 1874 adopted a revised liturgy, the use of which is optional. The prescribed order of public worship in the morning is as follows: 1, after a space for

private devotion, invocation; 2, salutation; 3, reading the ten commandments or some other portion of Scripture, or both; 4, singing; 5, prayer; 6, singing; 7, sermon; 8, prayer; 9, collection of alms; 10, singing; 11, benediction. In the other services the reading of the commandments is omitted, and the last service is always to be concluded with the doxology. Formerly the apostles' creed was recited, and a clerk (*voorlezer*), who was also chorister, conducted the opening services from his desk below the pulpit by reading the commandments and a chapter, and announcing and leading in the singing of a psalm. The minister had an hour glass standing on the pulpit, to measure the time to be occupied by the sermon, which was recommended not to exceed an hour. On some part of every Sabbath a portion of the Heidelberg catechism was expounded. Children were almost universally baptized, and provision was made for their instruction in Christian doctrine by parents, church officers, and schoolmasters. The school was an appendage of the church, taught by a schoolmaster appointed by the consistory, and was constantly visited by the minister and elders. The school came with the church into this country, but the continued connection became in time impracticable. Interest has lately been reawakened in this subject, and parochial schools have been established in some congregations. In public worship only such psalms and hymns are sung as have been recommended by the general synod. Singing in the English language was introduced in 1767. In 1813 the Rev. Dr. Livingston, by order of the general synod, compiled the "Book of Psalms and Hymns" now in use, to which large additions of hymns have been made. Another book called "Hymns of the Church," with tunes, was authorized in 1869, and is in use in many of the churches. The observance of the principal feast days, as Christmas, Easter, Ascension, and Whitsuntide, was denounced by the early synods in the Netherlands; but as it was found that the people would otherwise devote them to their pleasures, it was afterward ordained that public worship should be conducted on them. In accordance with this they were for a long time carefully observed by the church in America, nor has respect for them ceased in some of the congregations to this day.—The government of the church is according to the Genevan presbyterian model. The officers are ministers, elders, and deacons, to whom may be added professors of theology. The elders have in connection with the ministers the spiritual oversight of the church. They receive, watch over, dismiss, and discipline members. The board of elders corresponds to the session in the Presbyterian church. The deacons collect and administer alms. The minister, elders, and deacons, or the elders and deacons if there be no minister, compose the consistory, to which the government of the individual church belongs.

In the great majority of cases they are also the trustees to whom the management of the temporalities is committed. The elders and deacons are elected on the organization of a church by the male communicants, and subsequently either by the consistory or the communicants, and in both cases their names are published to the congregation for approval. They hold office for two years, at the expiration of which term they may be reelected. The classis corresponds to the presbytery in the Presbyterian church, and is composed of ministers, with elders delegated, one from each church within a certain district. The classis is a court of appeal from the judicial decisions of consistories. It approves of calls, dissolves pastoral connections, and ordains and deposes ministers. The particular synods, of which there are four, New York, Albany, New Brunswick, and Chicago, are delegated bodies composed of four ministers and four elders from each classis within the bounds of the synod. These are courts of appeal from the decisions of the classes; they form new classes, and transfer congregations from one classis to another. The general synod is the highest court of appeal, and is composed of three ministers and three elders from every classis in the connection. In a few instances of large classes, four ministers and four elders are delegated. It constitutes particular synods, appoints theological professors, has the management of the theological seminary and the various boards, and exercises a general supervisory power over the concerns of the church. It cannot alter or amend the constitution of the church, but may recommend alterations, which can be adopted only by the votes of a majority of the classes. At a meeting of the general synod held at Geneva, N. Y., in June, 1867, it was voted to drop the word Dutch from the corporate name of the body, it being alleged that many were repelled by this foreign designation from joining the church. The question was submitted to the classes, assented to, and the action completed at an extra session of the general synod in Albany, N. Y., Nov. 20 of the same year. A revised constitution was adopted in 1874. The reports of 1874 give the following statistics: particular synods, 4; classes, 34; churches, 489; ministers, 520; communicants, 69,149; contributions, \$276,464. "The Christian Intelligencer," which is devoted to the interests of the church and mainly supported by its members, is the oldest religious weekly in the city of New York next to the "New York Observer," having been established in 1828. The boards publish a semi-monthly paper called the "Sower and Gospel Field." There are two theological seminaries, one at New Brunswick, N. J., the other in connection with Hope college at Holland, Mich., the professors of which are appointed and the course of studies prescribed by the general synod, and which all students in theology contemplating entrance into the ministry of this church are by the con-

stitution required to attend. Much has been done recently for the completion of the endowment of the seminary at New Brunswick, and for furnishing it with the necessary buildings and library. The James Suydam hall contains a gymnasium, chapel, museum, and lecture rooms. The Gardner A. Sage library is a spacious fire-proof building. Many thousands of dollars have been contributed by various friends of the church for books, by the expenditure of which a theological library will be secured second in value to none in the country.

REFORMED CHURCH IN THE UNITED STATES (formerly GERMAN REFORMED CHURCH IN THE UNITED STATES OF AMERICA), a religious body which is an offshoot of the Reformed church of Germany. The first minister was the Rev. George Michael Weiss, who, aided by the classis of Amsterdam, emigrated with about 400 people of the Palatinate in 1727. They settled along the Skippach, in Montgomery co., Pa., and built a wooden church. The majority of the immigrants who followed these pioneers settled in Pennsylvania, E. of the Susquehanna; smaller numbers settled in New York, along the Hudson, in New Jersey, Maryland, and Virginia, and even extended into the Carolinas. But though the members of the church were soon counted by thousands, no effort was made to establish an ecclesiastical organization, and until the middle of the century the number of ministers was at no time more than three or four. In 1746 the Rev. Michael Schlatter was commissioned by the synods of North and South Holland to visit their German missions in America, and to regulate their ecclesiastical relations. After visiting all the German congregations, he assembled in Philadelphia the first synod (or, as it was then called, *coetus*) of the German Reformed church, Sept. 29, 1747. It consisted of 31 members, 5 ministers and 26 elders, who represented 46 churches and a population estimated at 30,000. Schlatter not only organized the church, but greatly promoted its growth by inducing clergymen in Germany to come as missionaries to America, and by collecting in England, Holland, Germany, and Switzerland a large fund for the support of ministers and teachers. The German Reformed *coetus* continued under the jurisdiction of the synod of Holland, sending its acts and proceedings to it for revision, till 1793, when it resolved to assume the right of self-government. It adopted a constitution, entitled *Synodal-Ordnung der hochdeutschen Reformirten Synode und der mit ihr verbundenen Gemeinden in den Vereinigten Staaten von Nord-Amerika* ("Constitution of the High German Reformed Synod and of the congregations connected with it in the United States of America"). The church, which was called High German in distinction from the Low German or Dutch, had at this time at least 150 churches, but only 22 ordained ministers. It increased rapidly in membership and congregations, but as the influx of clergymen who

had received their education at European universities ceased, and as the church had as yet no theological school of its own, the standard of ministerial education was considerably lowered. Here, as in the Reformed church of Germany, there was a general indifference to the original faith of the church, as embodied in the Heidelberg catechism. A reaction against this indifference began about 1815, and in 1820 the synod enjoined on all ministers to use no other book but the Heidelberg catechism in the instruction of youth preparatory to confirmation. The first theological seminary of the church was opened at Carlisle, Pa., in 1825. It was removed to York in 1829, to Mercersburg in 1835, and to Lancaster in 1871. In 1830 a high school was opened at York, which in 1835 was also removed to Mercersburg, and in 1836 received the name of Marshall college. In 1853 it was united with Franklin college at Lancaster. The first religious paper in English was established in 1828, the first German in 1836. Church boards for missions and beneficiary education were also organized. The German language, in which, with only two or three exceptions, all the pastors had conducted public worship till 1825, began in some districts to give way to the English, a transition which caused no little dissension and confusion, but was finally accomplished. The spread of the English language and the establishment of theological and classical schools led to a closer connection with other Protestant churches of the United States; and many ministers and congregations, chiefly those using the English language, showed a tendency to abandon some peculiar customs of the church, as catechization, confirmation, and the observance of great festivals, and to assimilate their church to the other Protestant denominations. But a powerful counter movement set in, which received its first impulses from the philosophical teachings of Dr. Rauch, first president of Marshall college, and found its ablest and most influential expounder in Dr. John Nevin. The controversy was long and animated. The organism of the church underwent considerable changes. In 1819 the constitution had been revised and amended. The territory was divided into classes (corresponding to the presbyteries of other churches), and the synod, instead of being a convention of all the ministers and one lay delegate from each parish, became a delegated body of ministers and elders elected by the classes. In 1824 the classes of Ohio became an independent body, assuming the name of the "Synod of Ohio," which in 1837 was changed into "Synod of Ohio and Adjacent States." The new synod, which in 1842 divided its territory into six classes, sympathized with the opponents of Dr. Nevin, who was sustained by the eastern synod. Both synods, however, felt the need of creating a higher body that should have jurisdiction over the whole church, and consequently agreed upon the organization of a triennial general synod, which met for the first

time in Pittsburgh, in November, 1863. In the same year the church celebrated the 300th anniversary of the publication and adoption of the Heidelberg catechism. The second general synod, held in Dayton, O., in 1866, authorized the organization of two more synods, the northwestern and the Pittsburgh. The general synod of 1869 resolved to drop the word German from the name of the church. The general synod of 1872 appointed a committee to confer with the Reformed church in America, formerly called the Protestant Reformed Dutch church, with a view to forming a union. The joint committee of the two churches, at a meeting held in November, 1874, agreed upon a report declaring that the rite of confirmation and the observance of festal religious days in the Reformed church in the United States were no serious obstacles to a union; but that, on the other hand, the fact that the Reformed church in America does, and the Reformed church in the United States does not, regard the Belgic confession and the canons of the synod of Dort as standards of faith, was a discrepancy seeming to preclude any further present negotiation in the direction of organic union. The growth of the church in the western states appears to have given to what has been called the "Low Church" party the ascendancy in the church; for at the general synod of 1872 the appeal of a prominent leader of that party, Dr. Bomberger, president of Ursinus college, against a resolution of the eastern (high church) synod censuring him for assuming the office of teacher of theology and giving theological instruction independently of any proper ecclesiastical supervision and direction, was sustained by a vote of 100 to 78.—The Heidelberg catechism is the only standard of doctrine. As this book was intended to harmonize the Melancthonian and Calvinistic tendencies, it has been construed by theologians of these two schools in different ways. In the German Reformed church the Melancthonian element has been predominant, and in the American branch of the church this element was more fully developed, so that many representative theologians incurred the charge of Romanizing tendencies. This was especially the case with the doctrine of the church, which is thus explained by a leading theologian of this (the "High Church") school, President E. V. Gerhart: "The German Reformed church denies that the church is an association of converted individuals; that the Bible is the foundation of the church; that this relation of the contents of the Bible to the individual is immediate; that Protestantism has its ground immediately in the Sacred Scriptures. On the contrary, the church affirms that the person of Christ is the true principle of sound theology; that the Christian church is an organic continuation in time and space of the life powers of the new creation in Christ Jesus; that private judgment is subordinate to the general judgment of the church, as ex-

pressed particularly in the œcumenical creeds; that the individual comes to a right apprehension of the contents of the Bible through the teaching of the church; that Protestantism is a historical continuation of the church catholic, in a new and higher form of faith." The worship of the church is liturgical. The first ministers in America brought with them the liturgies of those sections of Germany and Switzerland from which they emigrated, a preference being generally given to the Palatine liturgy. A new liturgy prepared by Dr. Mayer, and adopted in 1840, did not sufficiently satisfy the theological (high church) school which had gained predominance in the church, and in 1847 a new one, known as the provisional liturgy, was reported by a special committee to the eastern synod, and by the latter recommended to the churches for trial. As it evoked an animated controversy, it was referred for revision to a committee which included Dr. Nevin, Dr. Schaff, Dr. Gerhart, Dr. Harbaugh, and Dr. Bomberger. This committee in 1866 reported a book, entitled "An Order of Worship for the Reformed Church." The eastern synod authorized its use by a vote of 53 to 14, while the general synod approved it by only a small majority (66 to 55) as "an order of worship proper to be used."—The government of the church is presbyterian. Each congregation is governed by a consistory composed of the pastor, elders, and deacons. The elders and deacons are chosen by the communicant members, and are ordained by laying on of hands. The consistory is subordinate to the classis, which consists of all the ministers and one elder from each parish of a district. The synod is composed of ministerial and lay delegates of several classes, and meets annually. The general synod, which meets triennially, is made up of delegates, ministerial and lay, from all the classes of the church. It is the duty of each pastor to catechise all the children and youth regularly, and reception into the full communion of the church, which is preceded by an examination of the candidates in the presence of the elders, takes place by the rite of confirmation. Christmas, Good Friday, Easter, and Whit Sunday are regarded as high church festivals, and are observed with much solemnity.—The reports for 1874 give the following statistics: particular synods, 5; classes, 38; ministers, 597; congregations, 1,825; communicants, 135,792; unconfirmed members, 82,249; Sunday schools, 1,187; scholars in the same, 69,132; amount of benevolent contributions, \$86,238. Eleven English and five German papers are published in the interest of the church; and there are 16 theological and literary institutions under its control.—See Dr. E. V. Gerhart, "The German Reformed Church" (1863).

REFRIGERATION. See FREEZING, ARTIFICIAL.

REFRIGERATOR (Lat. *refrigere*, to make cool), an apparatus by which various articles, generally meats and drinks, are kept cool or are

reduced in temperature. The ordinary food refrigerator is usually in the form of a chest which has a compartment for ice and one or more compartments for the food. Most of the older forms of refrigerators did not completely separate the ice from the food compartment, and many of them were merely chests with double sides separated by some non-conducting substance, as charcoal, in which the ice as well as the articles to be kept cool were placed on shelves indiscriminately. In either case the moisture from the evaporating ice filled the whole apparatus, and caused the contents to begin decaying soon after their removal, and indeed prevented their being preserved long while they were within it. In the presence of moisture, particularly when it contains the effluvia from various meats and articles of food, decomposition will go on even at a temperature considerably below the freezing point, and this cannot be secured by the presence of ice. In a dry atmosphere, like that of the Andes or the California coast, meats may be preserved without ice. If a current of air is made to circulate in a chamber surrounding an ice box, much of the moisture of the air will be condensed upon the box, and there will also be a constant collection of impurities contained in the air. To make such a refrigerator efficient, the air must be first dried by passing it through a vessel containing chloride of calcium or some substance which will rapidly absorb moisture. In either case the caloric absorbed by the ice to cool a continuous current causes it to melt rapidly. An efficient method is to place a tight ice box within a tight meat box, or surround the latter with an ice chamber, the meats to be first cooled in the open air.

REFUGIO, a S. county of Texas, on the gulf of Mexico, bounded N. E. by the Guadalupe river and Espiritu Santo bay, and S. W. by the Aransas, and intersected by the San Antonio, Mission, and other rivers; area, 1,310 sq. m.; pop. in 1870, 2,324, of whom 246 were colored. It has a level surface and a generally fertile soil. Aransas bay lies chiefly in the S. part. The chief productions in 1870 were 41,555 bushels of Indian corn, 20,504 of sweet potatoes, and 13,955 lbs. of wool. There were 9,949 horses, 1,002 mules and asses, 101,925 cattle, 4,858 sheep, and 4,333 swine. Capital, Refugio.

REGATA. See ROWING.

REGELATION. See ICE, vol. ix., p. 146.

REGENSBURG. See RATISBON.

REGGIO (REGGIO NELL' EMILIA). I. A N. province of Italy, bordering on Cremona, Mantua, Modena, Massa e Carrara, and Parma; area, 877 sq. m.; pop. in 1872, 240,635. The principal rivers are the Po, which forms the N. W. boundary, and its affluent the Enza. The mountains toward the south, in the direction of the Apennines, are barren, but the less elevated parts and the valleys are very fertile. It comprises the districts of Reggio d' Emilia and Guastalla.—Formerly the prin-

cial parts of it formed a duchy, successively ruled by the houses of Este, Correggio, Gonzaga, Visconti, and others, and from about 1527 to 1859 by the dukes of Este (afterward of Modena), excepting during the French domination (1796-1814). Marshal Oudinot was made duke of Reggio. **II.** A city (anc. *Regium Lepidi*), capital of the province, 16 m. W. N. W. of Modena; pop. about 21,000 (as a commune, in 1872, 50,657). It is the seat of a bishop, and has broad streets, some lined with arcades, a fine cathedral and several other churches, convents, a museum and public library, and trade in wine, silk, cheese, and hemp. It is the birthplace of Ariosto, whose 400th anniversary was celebrated in 1874.—*Regium Lepidi* is supposed to have been founded by *Æmilius Lepidus*, the constructor of the *Æmilian way*. It was destroyed by the Goths in 409, and refounded by Charlemagne.

REGGIO DI CALABRIA. **I.** Or *Calabria Ulteriore I.*, a province forming the S. extremity of Italy, bordering on the Ionian sea, the strait of Messina, the Tyrrhenian sea, and the province of Catanzaro; area, 1,515 sq. m.; pop. in 1872, 353,608. It is traversed by many mountains and numerous small rivers. The country is not favorable to pasturage and agriculture, but is rich in timber, oil, silk, and minerals. (See *CALABRIA*.) The province is divided into the districts of Reggio, Gerace, and Palmi. **II.** A city (anc. *Rhegium*), capital of the province, on the strait and 9 m. S. E. of the city of Messina; pop. about 18,000 (as a commune, in 1872, 35,235). It is situated in a most beautiful region, is the seat of an archbishop, and has a handsome cathedral, a theological seminary, a gymnasium and public library, an active trade in local products, and manufactories of silks, linens, and pottery. Its bay presents the remarkable optical phenomenon known as *fata morgana*.—The ancient *Rhegium* was an important city of *Magna Græcia*, colonized by Eubœans and Messenians about 740 B. C. It was governed under an aristocratic constitution by a body of 1,000. Under *Anaxilaus*, who gained supreme power in the early part of the 5th century B. C., it became very prosperous. His sons, however, were expelled by the people. In 427 the *Rhegians* supported the Athenians against Syracuse, but in 415 remained neutral. In 388 *Dionysius the Elder* besieged the city, which was desperately defended by *Phyton*. After 11 months of resistance it was compelled by famine to surrender. *Phyton* and his family were put to death, the inhabitants were sold as slaves, and the walls were razed to the ground. It was partially rebuilt by *Dionysius the Younger*. On the arrival of *Pyrrhus* in Italy in 280 it formed an alliance with the Romans, and received a garrison of 4,000 Campanian troops. The soldiers, taking advantage of an alleged defection, massacred the male inhabitants, took possession of their property, and made slaves of their wives and children. In 271 the Ro-

mans reduced the city after a long siege, executed all the surviving soldiers, and *Rhegium* came again into the hands of its former inhabitants. During the Punic wars it remained faithful to Rome. After the fall of the western empire it was subject to the emperors of the East. It was taken by *Totila* in A. D. 549, by the Saracens in 918, by *Robert Guiscard* in 1060, and by *Pedro III.* of Aragon in 1283; and during the 16th century it was three times sacked by the Turks. The modern city was almost entirely destroyed by the earthquake of 1783, and rebuilt on a larger and finer scale; and it was again much damaged by an earthquake in 1841.

REGILLUS, Lake, a small body of water in *Latium*, where, according to the historical legends of ancient Rome, was fought the battle which decided the fate of the last Roman king (about 498 B. C.). Its site has been considered doubtful, but it is now generally supposed to be identical with the lake of *Cornufelle*, at the foot of the hill on which stands the town of *Frascati* (the ancient *Tusculum*), about 10 m. S. E. of Rome; this lake was formed by a volcanic crater about half a mile in diameter, and was artificially drained in the 17th century. Here *Tarquin the Proud*, having after the failure of *Porsena's* expedition enlisted the Latins in his cause, with his son-in-law *Octavius Mamilius* gave battle to the Romans under the dictator *Albinus Postumius*, was wounded and utterly defeated, and fled alone from the field. The chiefs on both sides were nearly all killed or wounded. According to the tradition, the Romans owed their victory to *Castor* and *Pollux*, who were seen to charge at the head of their cavalry, and who first made it known in the forum at Rome. There a temple was dedicated to them, where the day (July 15) was afterward annually celebrated.

REGIMENT, a body of troops, whether infantry, cavalry, or artillery, numbering from 800 to 2,400 men, and commanded by a colonel and one or more lieutenant colonels and majors, according to the number of battalions into which it is divided. The battalions are subdivided into companies, each of which is commanded by a captain and one or more lieutenants. The regiment forms the third subdivision of an army corps, or, where the division by corps is omitted, of an army, two or more regiments constituting a brigade, and two or more brigades a division. It originated in the French service about 1560.

REGIOMONTANUS, or *Johann Müller*, a German mathematician, born at Königsberg, Franconia (whence his Latin name), June 6, 1436, died July 6, 1476. He completed his studies under *Purbach* at Vienna, whom he succeeded in 1461 as professor of mathematics. Subsequently he lectured on astronomy at Padua, spent some time at the court of *Matthias Corvinus* in Hungary, and resided at Nuremberg from 1471 to 1474, when Pope Sixtus IV.

called him to Rome to reform the calendar, and not long before his death appointed him bishop of Ratisbon. According to some authorities, he was assassinated by the sons of George of Trebizond, in whose translations Regiomontanus had detected grave errors; according to other accounts, he died of the plague. He was the first in Europe to publish an astronomical almanac, improved the knowledge of algebra, introduced decimal fractions, greatly promoted the science of trigonometry, and was the most eminent astronomer that Europe had produced. His works include *Calendarium* (in Latin and German, Nuremberg, about 1473); *Ephemerides* from 1475 to 1506, continued by Bernhard Walther and published in 1544 by Schonerus; *De Reformatione Calendarii* (Venice, 1489); *De Cometæ Magnitudine, Longitudineque* (Nuremberg, 1531); *De Triangulis* (1533); and *Tabula Directionum Projectionumque in Nativitatibus multum utiles* (Venice, 1585).—See *Regiomontanus als geistiger Vorläufer des Columbus*, by Alex. Ziegler (Langensalza, 1874).

RÉGIS, Jean Baptiste de, a French geographer, born at Istres in Provence about 1665, died in China about 1737. He was a Jesuit, and was sent to China as a missionary about 1700. His scientific attainments gained him a place at court and the favor of the emperor Hang-he, who in 1707 placed him at the head of a commission of Jesuits for making a survey and drawing up a map of the Chinese empire. Beginning with the great wall and the adjacent provinces, he completed a 15 ft. map of them, which he presented to Hang-he in January, 1709. He then drew up maps of Mantchooria, Pecheli, and the region drained by the Black river (1710); in 1711-13 he surveyed and mapped Shantung, Honan, Nanking, Chekiang, and Fokien. The health of his companions failing, he accomplished alone the survey of Yunnan, and, assisted by Father Fridelli, he finished the maps of Kweichow and Howkwang (now Hupeh and Hunan). While thus completing surveys of extraordinary magnitude, he also wrote a full history of his labors, which is in part condensed in the preface to Du Halde's *Description de la Chine* (4 vols. fol., Paris, 1735). Of the copious memoirs which he composed on the topography of the various provinces, their resources, and the manners and customs of the inhabitants, only two fragments are published by Duhalde in vol. iv. of his *Description*, one relating to Corea and the Coreans, and the other on Thibet and the hierarchy of the lamas. His knowledge of Chinese enabled him to translate into Latin the *Yih-king*, with copious notes and dissertations (edited by Julius Mohl, 2 vols., Stuttgart and Tübingen, 1834), the manuscript of which is in the national library of Paris. His labors were interrupted in 1724, when the emperor Yung-ching proscribed the Christian religion.

REGNARD, Jean François, a French dramatist, born in Paris in February, 1655, died Sept. 4,

1709. He inherited great wealth and led a roving life. In Bologna he fell in love with a lady whom he made the heroine of his novel, *La Provençale*. She and her husband, whom he designates as M. de Prade, left Genoa on the same boat with him in 1678, and they were all captured by Algerine pirates. He and the lady were ransomed, and together went to Paris in the belief that the husband was dead; but on finding him alive after reaching that capital, Regnard in despair resumed his wandering life. After exploring Lapland, and travelling through Poland, Turkey, Hungary, and other countries, he returned to France about 1683; and for most of the remainder of his life he was prominently connected with the ministry of finance, and his house in the rue Richelieu was a resort of wits. He was one of the best followers of Molière, and excelled as a satirical poet. His *Le joueur* (1696) is one of the masterpieces of the French stage. The best of the numerous editions of his works are by Crapelet (6 vols., 1822) and by Alfred Michiels, with an essay and biographical notices (2 vols., 1854).

REGNAULT, Alexandre Georges Henri. See supplement.

REGNAULT, Élias Georges Soulange Oliva, a French historian, born in London, April 22, 1801, died in Paris, Jan. 4, 1868. The son of a French physician, he studied law in Paris, and became an advocate. In 1848 he was a prominent official in the ministry of the interior, and subsequently in that of finance. He published histories of Ireland and England; *Histoire de Napoléon* (4 vols. 18mo, 1846-'7); *Histoire de huit ans* (3 vols., 1851-'4), as a continuation of the *Histoire de dix ans* by Louis Blanc, who however disputed its character as such; a history of the Danubian principalities, &c. He also translated works of Bentham and Wordsworth, and in conjunction with others Carlyle's "History of the French Revolution" (3 vols., 1866-'7).

REGNAULT, Henri Victor, a French physicist, born in Aix-la-Chapelle, July 21, 1810, died Jan. 10, 1878. He studied at the polytechnic school of Paris and was professor at Lyons till 1840, when his *Mémoire sur l'action du chlore sur l'éther chlorhydrique* secured his admission to the academy of sciences and his appointment to the chair of physical sciences in the polytechnic school, and in 1841 in the collège de France. He was chief engineer of mines from 1847 to 1854, when he became director of the porcelain works at Sèvres. In 1848 he received the Rumford medal from the royal society of London for his "Experiments to determine the Laws and the Numerical Data which enter into the Calculation of Steam Engines," and subsequently became one of the 50 foreign members of that body, which presented him with the Copley medal in November, 1869. His attention has been devoted chiefly to heat, and he was the first to demonstrate that the latent heat of steam diminishes

as the sensible heat increases, but in a slower ratio. He has also verified the law of Mariotte and Boyle on the compressibility of the gases. Accounts of his investigations on these subjects fill the 21st and 26th volumes of the *Mémoires* of the French academy of sciences. His *Cours élémentaire de chimie* (2 vols. in 4 parts, Paris, 1847-'9; 5th ed., 4 vols., 1859-'60) has been translated into several languages. Among his other works is an abstract of the preceding, *Premiers éléments de chimie* (1850; 4th ed., 1861).

REGNAULT, Jean Baptiste, a French painter, born in Paris in October, 1754, died there in November, 1829. He began life as a sailor, and subsequently studied in Paris and in Rome, where he was enabled to spend several years by winning in 1776 a first academical prize. His "Education of Achilles" and other works placed him in the front rank of the French school. He was professor at the school of fine arts from 1795 to 1818, when he was transferred to the polytechnic school.

REGNIER, Mathurin, a French poet, born in Chartres, Dec. 21, 1573, died in Rouen, Oct. 22, 1613. He was the son of Jacques Regnier, who established a tennis court in Paris, known as the *tripot Regnier*. He was educated for the church, and in 1593 went with the cardinal Joyeuse to Rome, where he remained about eight years, and subsequently returned with the duke de Béthune, French ambassador. After a life of dissipation he became in 1609 canon of the cathedral of Chartres. He was called the good Regnier on account of his amiability. Boileau, although objecting to his broad cynicism, characterized him as the satirical poet who before Molière gave the best insight into manners and life. Numerous editions of his works have appeared. The best are by Brossette (Amsterdam, 1729; London, 2 vols., 1736), Viollet-Leduc (1822; new ed., 1853), and Ed. de Barthélemy with additional poems, but not all well authenticated (1862).

REGULAR CLERKS OF ST. PAUL. See BAR-NABITES.

REGULUS, Marcus Atilius, a Roman general, died about 250 B. C. He was consul in 267, when he defeated the Sallentini, took Brundisium, and received a triumph. In 256, the ninth year of the first Punic war, he was a second time consul, and in conjunction with his colleague Manlius set out with a fleet of 330 vessels to invade Africa, defeated the Carthaginian fleet of 350 sail under Hanno and Hamilcar, landed at Clypea, and ravaged their territory. Toward the close of the year, by order of the senate, Manlius returned to Rome with his division of the forces. Regulus now defeated the three Carthaginian generals in a great battle in the mountains, and captured town after town, including Tunis. The Carthaginians sued for peace, but when the envoys protested against the extravagance of his demands, Regulus replied: "Men who are good for anything should either conquer or

submit to their betters." The negotiations were broken off, and Xanthippus, a Spartan, was placed at the head of the Carthaginian army, who defeated the Romans and took Regulus prisoner. After five years' captivity he was sent in 250 to Rome along with an embassy, on condition that he would return if the negotiations were unsuccessful. He persuaded the senate to refuse to make peace, and returned to Carthage. The story of his execution under the most barbarous tortures is now generally disbelieved.

REICHENBACH, Heinrich Gottlieb Ludwig, a German naturalist, born in Leipsic, June 8, 1793. He studied at Leipsic, took the degree of M. D., and in 1820 became professor of natural history in the medical and surgical school of Dresden. His most important work is his *Flora Germanica*, accompanied by an *Iconographia Botanica* (21 vols., Leipsic, 1823-'67). He has also published *Regnum Animale* (1834-'6, incomplete), *Vollständigste Naturgeschichte*, devoted to mammalia and birds (1845 *et seq.*), and other works.—His brother ANTON BENEDICT, born in 1807, professor of natural history at Leipsic till 1866, and his son HEINRICH GUSTAV, born in 1822, professor of botany there, have also published works on zoölogy and botany.

REICHENBACH, Karl, baron, a German naturalist, born in Stuttgart, Feb. 12, 1788, died in Leipsic, Jan. 19, 1869. He was educated at Tübingen. At the age of 16 he conceived the idea of establishing a new German state in one of the South sea islands; and for three years he devoted himself to this project, and had secretly formed a large association in Würtemberg, when it was suppressed by the French authorities on suspicion that its real objects were political, and Reichenbach was imprisoned. In 1821 he became connected with Count Hugo of Salm in the management of chemical works, iron furnaces, and machine shops at Blansko, Moravia, from which he soon secured an ample fortune; and about this time the king of Würtemberg made him a baron. From 1830 to 1834 he was engaged in the investigation of the complicated products of the distillation of organic substances, and discovered among them several compounds of carbon and hydrogen, the existence and useful properties of which were before entirely unknown; among these are creosote, paraffine, eupion, pittacal, and capnomor. He afterward entered upon an investigation of the manner in which the human system is affected by various substances, and was led to conceive the existence of a new imponderable agent, allied to electricity, magnetism, and heat, which emanates from most substances, and to the influence of which different persons are variously sensitive. Although he had given no attention to animal magnetism, the subject was inevitably encountered by him in these researches; which, however, he pursued independently of all experiments and theories that

had been made in that department. He applied the term *od* to the new force, the existence of which he believed he had established, and published *Physikalisch-physiologische Untersuchungen über die Dynamide des Magnetismus*, &c. (2d ed., 3 vols., Brunswick, 1849-50; translated into English); *Odisch-magnetische Briefe* (Stuttgart, 1852 and 1856; French translation, Paris, 1854; translated into English by Drs. Ashburner and Gregory); *Der sensitive Mensch und sein Verhalten zum Od* (2 vols., Stuttgart, 1854); and *Wer ist sensitiv, wer nicht?* (Brunswick, 1856).

REICHENBERG, a town of Bohemia, on the Neisse, 55 m. N. N. E. of Prague; pop. in 1870, 22,394. Next to Prague and Pilsen it is the most populous city of Bohemia, and it is one of the most flourishing centres of Austrian industry. It has a castle, several industrial and other schools, and a new theatre. The principal manufactures are woollen, cotton, and linen stuffs and yarn.

REICHSTADT, Duke of. See BONAPARTE, vol. iii., p. 48.

REID, Mayne, a British novelist, born in the north of Ireland in 1818. He is the son of a Presbyterian minister, and was educated for the church, but, being fonder of adventure than of theology, set out in 1838 for America. Arriving at New Orleans, he engaged in trading and hunting excursions up the Red and Missouri rivers, and travelled through nearly every state of the Union. Subsequently he settled in Philadelphia, joined the army in the Mexican war, and was wounded in the assault upon Chapultepec. In 1849 he set out to fight for the Hungarians during their struggle with Austria; but by the time he reached Paris the revolution had been suppressed. He has since resided chiefly in London, and has written a series of very popular books for boys. Among his works are: "The Rifle Rangers" (1849), "The Scalp Hunters" (1850), "The Quadroon" (1856), "Osceola" (1858), "Ran Away to Sea" (1861), "The Maroon" (1862), "The Cliff Climbers" (1864), "Afloat in the Forest" (1866), "Quadrupeds" (1867), "The Child Wife" (1868), "The Castaways" (1870), and "The Finger of Fate." In 1869 he established in New York a short-lived monthly magazine entitled "Onward."

REID, Thomas, a Scottish metaphysician, born at Strachan, Kincardineshire, April 26, 1710, died in Glasgow, Oct. 7, 1796. He graduated at Marischal college, Aberdeen, in 1726, was librarian of the college till 1736, and in 1737 was presented to the neighboring living of New Machar. In 1748 he published a paper in the London "Philosophical Transactions," in which he opposed the introduction of mathematical formulas into metaphysical and moral speculations. He was elected in 1752 professor of philosophy in King's college, his department comprehending logic, ethics, mathematics, and physics. His "Inquiry into the Human Mind on the Principles of Common Sense" (London,

1763) aimed at the refutation of Hume's skeptical theory. He introduced the doctrine of an original instinct or common sense as the ground of belief. In 1764 he was transferred to the university of Glasgow as professor of moral philosophy, and retired in 1781. In 1785 he published his "Essays on the Intellectual Powers of Man," consisting of his academical lectures (new edition by the Rev. James Walker, D. D., Cambridge, Mass., 1850), and in 1788 his "Essays on the Active Powers of Man." In 1863 a complete edition of his works, with preface, notes, and supplementary dissertations by Sir William Hamilton, and a memoir by Dugald Stewart, was published in Edinburgh (2 vols. 8vo).

REID, Sir William, a British meteorologist, born at Kinglassie, Fifeshire, in 1791, died in London, Oct. 31, 1858. He entered the army as lieutenant of royal engineers in 1809, served under the duke of Wellington in the Peninsula, was in America in the war of 1812, and again served under the duke in Belgium in 1815, being present at the battle of Waterloo. In 1816 he took part, with the rank of captain, in the attack on Algiers. He subsequently became adjutant of the corps of sappers and miners, and in 1839 was elected a fellow of the royal society. He was appointed governor of Bermuda in 1838, and by his tact and skill greatly improved the agriculture of the island, its products being introduced through his efforts into the New York market. He was appointed governor of the Windward islands in 1846, and in 1848 returned to England, and was appointed commanding engineer at Woolwich. During the great exhibition of 1851 he was actively engaged in the promotion of its objects, and succeeded Robert Stephenson as chairman of the executive committee. In the same year he was appointed governor of Malta, and was knighted. He held that post through the Crimean war, was made a major general in 1856, and returned to England in 1858. Having been detailed to superintend the repairs of the injury done by a severe hurricane in Barbadoes in 1831, he devoted much time to the study of meteorology. He published "An Attempt to develop the Law of Storms by means of Facts, arranged according to Place and Time" (1838), and "The Progress of the Development of the Law of Storms," &c. (1849).

REIGATE, a market town of Surrey, England, 21 m. S. by W. of London, on the London and Brighton and Southeast railways; pop. in 1871, 15,916. It has a church containing several costly monuments, a grammar school, and the remains of a castle, with a cave where the barons are said to have met to arrange the articles of Magna Charta. It carries on a brisk trade in fuller's earth and fine sand used in the manufacture of glass.

REIL, Johann Christian, a German anatomist, born in East Friesland, Feb. 28, 1759, died in Berlin, Nov. 22, 1813. He studied at the universities of Göttingen and Halle, taking his

degree at the latter in 1782. In 1787 he was made professor of clinical medicine at Halle, and in 1810 was called to Berlin on the establishment of the university in that city. His name is perpetuated in connection with the "island of Reil," an isolated cluster of cerebral convolutions, situated at the bottom of the fissure of Sylvius, between the anterior and middle lobes of the cerebrum. Reil conducted for 20 years a periodical entitled *Archiv für Physiologie*, and left various works on the structure of the nerves, clinical medicine, &c.

REIMARUS, Hermann Samuel, a German scholar, born in Hamburg, Dec. 22, 1694, died there, March 1, 1768. He was educated at Jena and at Wittenberg, made a journey through Belgium and a great part of England in 1720, became rector in Wismar in 1723, and in 1727 received the professorship of Hebrew in the gymnasium of Hamburg, afterward united with that of mathematics, which he held till his death. He married in 1728 the daughter of J. A. Fabricius, and was the author of the celebrated "Wolfenbüttel Fragments," published by Lessing in 1774-'8. These productions, which challenge the supernatural origin of Christianity, had been imparted by Reimar only to his intimate friends; and Lessing, who had obtained a copy, edited them as manuscripts belonging to the Wolfenbüttel library.

REIMS. See RHEIMS.

REINDEER (*rangifer tarandus*, Gray), the name usually given to the old world species of rangerine deer, of which the American woodland and barren ground caribou are believed to be mere varieties. The description and figure given under CARIBOU will answer for the European animal, which, like its American variety, differs greatly in size; the large Siberian variety is ridden by the Tungusians, who also use it for draught, as the Laplanders do their smaller animal. The tame reindeer of the Laplander does not exceed in size, and often does not equal, the English red deer or stag. After the casting of the coat the hair is brownish yellow, but as the dog days approach it becomes whiter, until it is at last almost entirely white. Round the eye the color is always black. The longest hair is under the neck. The mouth, tail, and parts near the latter, are white, and the feet at the insertion of the hoof are surrounded with a white ring. The hair of the body is so thick that the skin cannot be seen when it is put aside. When the hair is cast, it does not come away with the root, but breaks at the base. The horns are cylindrical, with a short branch behind, compressed at the top, and palmated with many segments, beginning to curve back in the middle, and are an ell and a quarter long. A single branch sometimes, but seldom two, springs from each horn in front, very near the base, frequently equaling the length of the head, compressed at the top and branched. The domestic reindeer of Lapland feeds wholly on a species of lichen peculiar to the country, for which he roots

under the snow with his nose, after the fashion of swine. He will eat no dried fodder, unless it be perhaps the river horsetail, *equisetum fluviatile*. To the Laplander the reindeer is invaluable, being in fact his ox, his sheep, and his horse, in one animal. He is too valuable to kill in general, although his meat is delicious; the milk of the herds is the principal support of the owner and his family; while, as an animal of draught, its speed, endurance, and particular adaptation to travelling on snow, render it the most valuable of creatures to men dwelling in the frozen latitudes. The ordinary weight drawn by this animal is 240 lbs., but he can travel with 300. Its speed and endurance are very great; it has been known to run at the rate of nearly 19 m. an hour, and it is not unusual for it to travel 150 m. in 19 hours. —During prehistoric times, in the latter part of the palæolithic division of the stone age, the reindeer inhabited southern France, and was hunted by the cave men. Its coexistence there with the musk ox and other arctic species shows that the climate was then much colder than at present, probably owing to the greater extent of the glaciers descending from the Alps and Pyrenees. The reindeer lived in central Europe in Cæsar's time, in the north of Scotland probably as late as the 12th century, and in Denmark as late as the 16th.

REINHART, Benjamin F. See supplement.

REINHART, Charles S. See supplement.

REINHOLD, Karl Leonhard, a German philosopher, born in Vienna, Oct. 26, 1758, died in Kiel, April 10, 1823. He was partially educated by the Jesuits, and after the suppression of that order became teacher of philosophy and mathematics and master of the novitiates in a Benedictine convent at Vienna. In 1783 he escaped by flight, and in 1784 turned Protestant at Weimar and married Wieland's daughter. In 1787 he was appointed professor of philosophy at Jena, which chiefly through his influence became a stronghold of the Kantian philosophy. In 1794 he was transferred to Kiel. Reinhold's chief merit is that of an interpreter and popular advocate of Kant's views. His works are numerous.

REINKENS, Joseph Hubert, a German theologian, born at Burtscheid, near Aix-la-Chapelle, March 1, 1821. He studied theology at Bonn, was ordained a priest of the Roman Catholic church, and became lecturer on church history at Breslau. He was cathedral preacher in 1852-'3, and in 1857 was appointed professor of theology. In 1870 he coöperated with Dollinger in the Old Catholic movement, opposing the dogma of infallibility, and published *Papst und Papstthum nach der Zeichnung des heiligen Bernhard von Clairvaux*. He was suspended by the bishop of Breslau, and the students of the university were forbidden to attend his lectures. He also published *Ueber päpstliche Unfehlbarkeit* (1870), which the bishop endeavored to suppress. On Aug. 11, 1873, he was consecrated bishop at

Rotterdam, by the Jansenist bishop of Deventer. Soon afterward he took an oath of allegiance to the government, and received from the emperor of Germany a patent of recognition, requiring his acknowledgment in all respects as a Catholic bishop. He issued a pastoral letter to the Old Catholics of Germany, and a second pastoral in reply to the papal encyclical of Nov. 21. He has also published *De Clemente Presbytero Alexandrino* (Breslau, 1851); *Hilarius von Poitiers* (Schaffhausen, 1864); *Martin von Tours* (Breslau, 1866); *Aristoteles über Kunst, besonders über Tragödie* (Vienna, 1870); and *Die päpstlichen Decrete vom 18 Juli 1870* (Munich, 1871).

REISKE, Johann Jakob, a German philologist, born at Zörbig, near Leipsic, Dec. 25, 1716, died in Leipsic, Aug. 14, 1774. He was educated at the university of Leipsic, where he acquired an extensive knowledge of Arabic. He afterward went to Leyden and became a corrector of the press, while his leisure hours were spent in ransacking the oriental treasures of the university library. He also studied medicine, and after remaining in Leyden eight years returned to Leipsic in 1746. He became professor of Arabic in 1748, and in 1758 was made rector of the St. Nicholas school in Leipsic. He edited a large number of Greek and Arabic works, and translated Demosthenes and Æschines. His life, partly autobiographical, was published by his wife (1785), and his correspondence with Moses Mendelssohn and Lessing appeared at Berlin in 1789.

REISSIGER, Karl Gottlieb, a German composer, born at Belzig, near Wittenberg, Jan. 31, 1798, died in Dresden, Nov. 7, 1859. He was intended for the church, but devoted himself to music, became professor at the musical institution of Berlin, and on the death of Weber succeeded him as chapelmaster at Dresden. His most successful operas are *Die Felsenmühle*, *Libella*, *Turandot*, *Adèle de Foix*, and *Der Schiffbruch der Medusa*. He is better known by the oratorio *David*, and his minor pieces, particularly his songs for the bass voice, such as Heine's *Zwei Grenadiere*.

RELIGIOUS ORDERS, the term applied to associations of men or women in the Roman Catholic church and the oriental churches, whose members live in common in convents. The history of these associations is given in the article **MONACHISM**. The common bond of union among all the religious orders, and which distinguishes them from other classes of associations, is retirement from the world, celibacy, and their organization, by means of religious vows, into communities of an entirely ecclesiastical character. The official list in the *Gerarchia Cattolica* of 1875, published in the Vatican, divides religious orders into six classes: 1, the regular canons, comprising the regular canons of the Most Holy Saviour of the Lateran, those of the basilica of Santa Croce, and the Premonstratensians; 2, regular clerks, embracing Theatines, Barnabites, Somaschians,

Jesuits, minor clerks, ministers of the infirm, fathers of the Mother of God, and fathers of the pious schools, or Piarists; 3, religious congregations, including the Passionists and Redemptorists; 4, ecclesiastical congregations, including the Doctrinarians, Lazarists or priests of the mission, pious laborers, oblates of Mary Immaculate, missionaries of the Precious Blood, institute of charity (Rosmini's), priests of the Sacred Hearts of Jesus and Mary, priests of the society of missions, priests of the resurrection, priests of the Holy Cross (of Le Mans), brothers of the Christian schools, and brothers of mercy; 5, monks, including the Basilians, Benedictines, Camaldules, hermits of Tuscany, hermits of Monte Corona, hermits of Vallombrosa, Cistercians, Trappists, Trappists of the Rancé reform, Benedictines of Monte Vergine, Olivetans, Silvestrines, Chartreux, Antonians (comprising Chaldeans, Maronites, and Armenians of Mt. Lebanon), Mekhitarists or Armenian Benedictines, and Basilians of the Greco-Melchite rite, comprising the Joanites of Palestine; 6, mendicants, including the Dominicans, minor Observants (comprising the reformed Observants, the minor Recollects, and Alcantarines), minor Conventuals, minor Capuchins, third order of St. Francis, Augustinians and discalced Augustinians, Carmelites of the primitive observance and reformed Carmelites, Servites or servants of Mary, Minims, *Mercedari* or fathers of the redemption of slaves, Trinitarians (primitive and reformed), Hieronymites or order of St. Jerome, hospitallers of St. John of God, and fathers of penitence. This classification is founded on the original distinction between the clergy or ordinary ministers of religion and the monks, who in the beginning were mostly or exclusively laymen, or who when priests lived in seclusion, and had no share in the ministrations of the clergy. The partly or wholly monastic forms adopted after the 4th century in the East, and especially in the West, by the cathedral and parochial clergy, caused them to be generally designated as *clerici canonici*. But this designation, particularly during the reign of feudalism, came to be applied exclusively to the clergy of cathedral or collegiate churches, who lived in common under some such rule as that of St. Augustine. This gave rise to the institution of canons regular. The parochial clergy were organized in this way by Eusebius, bishop of Vercelli (died 370), by St. Ambrose (died 397) in Milan, and by St. Augustine (died 430) at Hippo. This quasi-monastic form was propagated by St. Gregory the Great in Sicily and in Rome before his elevation to the papacy, and according to Lingard it was established in England by Augustin, archbishop of Canterbury, and prevailed in the chief churches there till supplanted by the strict Benedictine rule. The whole clergy of the British islands, as well as of several continental countries, continued at least during the missionary epoch to live in establishments called monasteries by contemporary

writers, though distinguished by them into clerical and monastic houses. Thus the first great class of religious associations embraces those anciently designated as the "regular clergy," that is, persons who were by vocation clergymen and embraced a monastic form of life; while the second class, or monks proper, comprises persons who are devoted to a life of seclusion, and are supposed to engage only by accident in the active ministrations of the parochial clergy. Hence both in time and in dignity the regular clergy are first. The canons regular of all denominations were always held by their rule to the public recitation or chanting of the divine office. The regular clerks of the society of Jesus were the first to deviate from this custom; and their exemption from choral service caused them to be bitterly assailed by other religious orders, who for this very reason refused for a long time to acknowledge them as one of the monastic brotherhoods. The third group of regular clerks, consisting of the Passionists and Redemptorists, are called in the list "religious congregations," because their vows have less of solemnity than those of the Jesuits, and are more binding than those of the following groups. They are, besides, held to recite the office in common. The members of the "ecclesiastical congregations" are held together by simple vows of obedience and poverty, or by promises of fidelity to their respective rules, and aim at discharging the clerical functions, or some duties closely connected therewith, such as the instruction of youth.—The monks proper are subdivided into two great families. The distinctive characteristics of the first are a life of seclusion, varied in some groups, like the Benedictines, by devotion to literary culture, and in others, like the Trappists, by a seeking after penitential austerity. The mendicants originally aimed at combining the contemplative and austere retirement of the monk with the active ministrations of the canons regular. They obtained their early reputation and popularity by living in poverty, prayer, and self-abnegation in the midst of the people to whose spiritual needs they ministered.—To most of the religious orders, soon after their formation, nuns of the same rule attached themselves. They were often called the second branch of the order, and their convents were generally under the ecclesiastical jurisdiction of the priests of the order. Besides the nuns, most of the orders received numerous additions by admitting lay brothers (*fratres conversi*) or lay sisters (*sorores conversæ*), who were charged with the performance of the housework and with keeping up communication with the world.—The Protestant churches in general have declared themselves opposed to the fundamental principle of monastic institutions; but in modern times several such communities, living in common and binding themselves to the observance of a rule, have been formed. In the church of England

an institution of sisterhoods has been considerably extended under the auspices of the so-called high church party. More recently an Anglican clergyman, the Rev. Mr. Lyne, assuming the name of Father Ignatius, endeavored to establish an Anglican branch of the Benedictine order; but the first monastery at Norwich, after the trial of a few years, had to be abandoned. Another clergyman tried to revive the canons regular of the Augustinian order, but, although the number of those who advocate the revival of monasticism in the church of England has considerably increased, notable results have not yet been obtained. In the Evangelical church of Germany communities of women, called deaconesses, were established for charitable purposes, especially for nursing the sick. This institution has assumed large dimensions and established branches in many other countries. (See DEACONESSES.) The most curious example of a Protestant religious order is found in the United States, among the Seventh-Day German Baptists or Seventh-Day Dunkers. (See DUNKERS.)

REMAINDER, in law, an interest in that which remains of a whole estate, after a partial or particular estate, as it is called, which was reserved out of the whole, has been determined. Like many other branches of the common law, it had its foundation in the feudal polity. In the long lapse of time, and under the influence of other branches of the English real property law, the learning of remainder has been wrought out into manifold distinctions and refinements. Sir Edward Coke says a remainder is "a remnant of an estate in land, depending upon a particular prior estate, created at the same time and by the same instrument, and limited to arise immediately on the determination of that estate, and not in abridgment of it." Thus, if a man who is seized in fee of lands grant them to A for 20 years, and, after that term has expired, to B and his heirs forever, A is tenant for years, and B has remainder in fee. But the residue of the estate after A's term may be still subdivided; for example, the limitation to B may be for life, then a limitation to C in tail, remainder over to D in fee. It matters not how many partial estates may be thus successively reserved or carved, as the phrase is, out of the fee; all together, with the final limitation, form one whole estate.—It is one of the cardinal rules respecting remainders, that no remainder can be limited upon or after the grant of an estate in fee, for the fee is the whole and there can be nothing left. Nor can there be a remainder without a prior partial estate. This partial or particular estate is also essential to the existence of any subsequent remainder that amounts to a freehold; for, by an old rule of the common law, a freehold cannot be created to commence *in futuro*, but must commence at the time of the grant; and inasmuch as, with all partial estates, the remainder forms but one whole, delivery of possession to the first particular tenant vests

possession in the freehold tenant also. The seisin which the grantor gives to the first taker is transmitted by him, and by each, to his successor, until it passes at last to the first remainderman. Each estate supports that which follows it. Hence arises another cardinal rule, that the remainder must vest in the grantee during the continuance of the partial estate, or on the instant that it is determined. Thus, if A and B be joint tenants for life, remainder to the survivor in fee, on the death of A the joint estate is severed; B becomes in the moment of A's death the designated remainderman, and the remainder is good. But if the limitation be to A for life, remainder to the son of B in tail, and A die and so his estate determine before B have a son, then the remainder fails.—Remainders are either vested or contingent. They are vested when there is an immediate right of present enjoyment, or a present fixed right of future enjoyment, it being the present capacity of taking effect in possession if the possession were to become vacant, and not the certainty that the possession will become vacant before the estate limited in remainder determines, that distinguishes a vested remainder from one that is contingent. Thus a limitation to A for years, remainder to B and the heirs of his body, gives B a vested remainder, for he is capable of taking should the particular estate fall in, though it is not certain that he will not die without heirs before A's death. A contingent remainder depends on an event or condition which may either never happen or be performed, or not till after the determination of the preceding estate; or, to use the definition of the New York statute, which Chancellor Kent commends for its brevity and precision, a remainder is contingent while the person to whom or the event upon which it is limited to take effect remains uncertain. An example of a remainder contingent as to the person would be a limitation to A for life, remainder to B's eldest son (as yet unborn) in tail. This last limitation is contingent, because it is uncertain whether a son will be born to B; and if A dies before that happens, the remainder is gone. A case of contingency in respect to the event would be presented by a limitation to A for life, and in case B survives him, then to B in fee. Here the uncertainty of B's surviving A is that which renders the remainder a contingent one.—The English doctrine of remainders, that is, the common law doctrine, remains unaltered in most of the United States. In one or two states slight changes, and in New York some which are quite material, have been made by statute.

REMBRANDT VAN RYN, Paul Harmens, a Dutch painter, born in Leyden, July 15, 1607, died in Amsterdam, Oct. 8, 1669. He was the son of a miller, and the suffix van Ryn was derived from his birth in a windmill on the bank of the Old Rhine (Oude Ryn). He was first placed with Jacob van Swanenburch of Leyden, and afterward studied under Pieter Lastman at

Amsterdam. About 1623 he fitted up a studio in his father's mill. It is supposed that from noticing the effects produced upon surrounding objects by the one ray admitted into the lofty chamber of the mill from the small window which formed its ventilator, he derived those notions of color and powerful contrasts of light and shadow which made him the great master of *chiaroscuro*. He produced his first great work, a portrait of his mother, in 1628, and in 1630 he settled in Amsterdam. His pictures brought large prices, pupils flocked to him from all parts of northern Europe, for the instruction of each of whom he received 100 florins a year, and from his etchings, which he produced in great numbers and which were esteemed as highly as his paintings, his profits were also considerable. He married Saskia van Ulenburgh in 1634, and had four children, none of whom survived him. He mingled little in society, but passed hours at the ale house. A second marriage involved him in difficulties; he was declared a bankrupt in 1656, and the remainder of his years were spent in poverty. As a historical painter Rembrandt held that the imitation of vulgar nature was preferable to the cultivation of ideal beauty; and his manner depends upon the elaboration of a single element in art, that of light and shade. His merits and defects are equally striking. Among his portraits, that of "Nicholas Tulp dissecting in the Presence of his Pupils," the *Staalmeesters*, or council of one of the guilds of Amsterdam, the "Ship Builder and his Wife," the "Jew Merchant," and the "Night Watch" are most esteemed. Of his historical pictures the most remarkable are "Duke Adolphus of Gueldres threatening his Father," "Moses destroying the Tables of the Law," "The Sacrifice of Abraham," "The Woman taken in Adultery," "The Descent from the Cross," "The Nativity," "Christ in the Garden with Mary Magdalene," and "The Adoration of the Magi." His peculiar style is perhaps more strikingly displayed in his etchings than in his paintings. They were a great source of profit to him, and one, "Christ healing the Sick," was called the "Hundred Guilders," from the fact that he refused to sell it for less than that sum. In 1868 a second-state impression of this plate was sold in London for £1,180. His paintings, of which 640 are specified in Smith's *Catalogue raisonné*, are variously valued at from \$500 to \$20,000. The best of them are still owned in Holland.—The most authentic account of his life is in French by C. Vosmaer (2 vols., the Hague, 1869). See also *Rembrandt, discours sur sa vie et son génie*, &c., translated from the Dutch of P. Scheltema (Paris, 1866).

REMORINO. See RAMORINO.

REMSCHIED, a city of Rhenish Prussia, 6 m. S. S. E. of Elberfeld; pop. in 1871, 22,017. It is celebrated for manufactures of iron and

steel, especially locks, nails, and cutlery, which have grown up within the past 60 years, the population in 1816 being but about 7,000. The immediate region yields neither iron nor coal, but its numerous streams furnish abundant water power. The number of different articles manufactured is said to be not far from 2,000, which are known in Germany as *Remscheider Waaren*.

REMUS. See ROMULUS.

RÉMUSAT. I. *Claire Elisabeth Jeanne Gravion de Vergennes*, countess de, a French authoress, born in Paris, Jan. 5, 1780, died there, Dec. 16, 1821. She was a grandniece of Vergennes, prime minister under Louis XVI. In her youth she was celebrated for her beauty, under the name of Clary, and was a friend and neighbor of Mme. d'Houdetot at Sannois. She married Count de Rémusat, afterward chamberlain of Napoleon, in 1796, and became an intimate friend and lady-in-waiting of Josephine. Among her writings is an *Essai sur l'éducation des femmes*, which was published by her son (1824; new ed., 1842). II. *Charles François Marie de*, count, a French author and statesman, son of the preceding, born in Paris, March 14, 1797, died there, June 6, 1875. In 1830 he was elected to the chamber of deputies, where he became a follower of Guizot. He held office in 1836 under Molé, and in 1840 as minister of the interior under his life-long friend Thiers; and he was a member of the chamber till 1848, and of the subsequent assemblies till the *coup d'état* of Dec. 2, 1851, when he was banished, returning in September, 1852. In 1871 he became minister of foreign affairs. In 1873 he was defeated as a candidate for the national assembly by the workmen of Paris, and soon afterward he retired with Thiers (May 24). He was a prominent member of the academy, and Royer-Collard described him as "the first of amateurs in everything." His principal works are: *Essais de philosophie* (2 vols., 1842); *Abélard* (2 vols., 1845); *Passé et présent* (2 vols., 1847); *Saint-Anselme de Cantorbéry* (1853); *Bacon, sa vie, son temps et sa philosophie* (1857); *L'Angleterre au XVIII^e siècle* (2 vols., 1856); *Histoire de la philosophie en Angleterre depuis Bacon jusqu'à Locke* (2 vols., 1875); and *Lord Herbert de Cherbury, sa vie et ses œuvres, ou Les origines de la philosophie du sens commun et de la théologie naturelle en Angleterre* (1875).

RÉMUSAT, Jean Pierre Abel, a French orientalist, born in Paris, Sept. 5, 1788, died of cholera, June 4, 1832. While a laborious student of medicine he taught himself Chinese and several Tartar languages, of the latter making his own vocabulary. In 1811 he published two works, the results of his studies. In 1813, while he was in active practice as a surgeon, two more volumes appeared. In 1814, a chair of Chinese and Mantchou having been founded in the collège de France, he was made professor. Rémusat's scientific studies aided his linguistic labors; but his

Tableau complet des connaissances des Chinois en histoire naturelle was never finished. His chief works are: *Plan d'un dictionnaire chinois* (1814); *Recherches sur les langues tartares, ou Mémoires sur différents points de la grammaire et de la littérature des Mantchoux, des Mongols, des Ouigours et des Thibétains* (1820); and *Éléments de la grammaire chinoise* (1822).

REMY, or *Remi* (Lat. REMIGIUS), *Saint*, called the apostle of the Franks, born at Cerny, near Laon, about 439, died in Rheims, Jan. 13, 533. He was elected bishop of Rheims, where he had studied, in his 22d year, and with the aid of King Clovis, whom he baptized, spread the knowledge of Christianity among the people. Apollinaris Sidonius, his contemporary, says he was the most eloquent man of the age. He established bishops in the cities of Tournay, Laon, Arras, Thérouanne, and Cambrai. His feast is celebrated on Oct. 1. His shrine is in the beautiful abbatial church of St. Remy at Rheims. See Butler's "Lives of the Saints," and lives of St. Remy by Armand-Prior (Paris, 1846) and Aubert (1849).—There are two other saints of the same name: a bishop of Strasbourg, who died in 803, and an archbishop of Lyons, who died in 875.

RENAISSANCE (Fr., new birth), the designation of a peculiar style of architecture and ornamentation, founded on the antique, which took its origin in Italy about the commencement of the 15th century (see ARCHITECTURE, vol. i., p. 664); also of the period commencing with the 14th and ending with the first half of the 16th century, which witnessed the revival of classical literature and the fine arts in southern Europe.—See Pater, "Studies in the History of Renaissance" (London, 1873), and John Addington Symonds, "Renaissance in Italy" (London, 1875).

RENAN, Joseph Ernest, a French philologist, born at Tréguier, department of Côtes-du-Nord, Feb. 27, 1823. He was destined for the church, studied Hebrew, Arabic, and Syriac in Paris, and in 1847 obtained the Volney prize for a treatise on the Semitic languages, afterward published as the first part of an *Histoire générale et système comparé des langues sémitiques* (8vo, 1855; 4th ed., enlarged, 1864). He was sent by the academy of inscriptions and belles-lettres in 1849 on a literary mission to Italy, and brought back materials for a historical essay on the philosopher Averroes, which was published under the title *Averroès et l'averroïsme* (1852). In 1851 he was attached to the department of manuscripts in the national library, and in 1856 was elected a member of the academy of inscriptions and belles-lettres. In 1858 he published a translation of the book of Job, with an essay on the age and character of the poem; and in 1860 a translation of the book of Canticles. On the occupation of Syria by the French in 1860, he was sent with the army at the head of a scientific commission, and explored the sites of Tyre and Sidon, the Lebanon, and other localities. In 1862 he was ap-

pointed professor of Hebrew in the collège de France; but his opening lecture excited such intense opposition that his appointment was not confirmed, and he was dismissed from the chair in 1864. In connection with this subject he published a pamphlet which passed through five editions. In 1863 his *Vie de Jésus* appeared, treating the gospel narrative as little more than a legendary romance. It passed through 13 editions in five years, and was immediately translated into the different languages of Europe (English translation by Charles E. Wilbour, New York, 1863). This work was intended to be the first of a series under the general title *Histoire des origines du Christianisme*, which he has continued in *Les apôtres* (1866), *Saint Paul* (1869), and *L'Antéchrist* (1873), to be followed by a fifth work entitled *Les derniers hommes apostoliques*. He has also published *Etudes d'histoire religieuse* (1857; revised ed., 1864); *De l'origine du langage* (1858); *Essais de morale et de critique* (1859; English translation by O. B. Frothingham, New York, 1864); *Nouvelles considérations sur le caractère général des peuples sémitiques* (1859); *Mission de Phénicie* (1864 et seq.); *Nouvelles observations d'épigraphie hébraïque* (1867); *Rapport sur les progrès de la littérature orientale* (1868); *La réforme intellectuelle et morale* (1872); and *De la part des peuples sémitiques dans la civilisation* (7th ed., 1875).

RENDEL, James Meadows, an English engineer, born near Dartmoor, Devonshire, in 1799, died in London, Nov. 21, 1856. He was early employed in the construction of bridges, and from 1824 to 1827 was engaged upon that across the Laira within the port of Plymouth. In 1831 he introduced a new system of crossing rivers by means of floating bridges and steam power. His most celebrated achievements are the harbors of refuge at Holyhead and Portland.

RENSBURG, a town of Prussia, in the province of Schleswig-Holstein, on the Eider, 54 m. N. W. of Hamburg; pop. in 1871, 11,514. The old town stands on an island in the channel of the Eider, and the new on the S. arm of the river. Beyond the N. arm is another part of the town called Schleuskühle or Kronwerk. During the Schleswig-Holstein war of 1848-'51 it was in the hands of the Germans. The strong fortifications were razed by the Danes in 1852.

RENÉ I., surnamed the Good, duke of Anjou, count of Provence, and titular king of Naples, born in Angers, Jan. 16, 1409, died in Aix, July 10, 1480. He was the second son of Louis of Anjou (crowned king of Naples in 1384) and Yolande, daughter of the king of Aragon. Louis was never able to make good his rights, although his eldest son Louis III., having been adopted by the queen Joanna II., gained possession of the throne. He died Nov. 15, 1434, and left Anjou and Provence, together with his claims upon Naples, Sicily, and Jerusalem,

to his brother René, whom Joanna II., dying in 1435, also appointed her heir. In 1430 René, as the successor of his maternal great-uncle, had become duke of Bar, and in 1431, on the death of his father-in-law, Duke Charles of Lorraine, had been confirmed by the estates in the possession of that duchy. But his claims were contested in the same year by the count of Vaudemont, nephew of Charles, by whom he was taken prisoner, and the decision of the question of succession was left by the nobility of Lorraine to the emperor Sigismund. René was released for a year, but compelled to give his sons as hostages. The emperor finally decided in his favor. Vaudemont would not submit, and René was compelled to return to prison. A few weeks afterward a deputation brought to him the crown of Naples and Sicily. Unable to obtain release, he appointed his wife Isabella regent of Anjou, Provence, Naples, and Sicily. She arrived in Italy on Oct. 18, 1435, but found herself at once in conflict with the party of King Alfonso of Aragon. In 1437 René purchased his freedom and the acknowledgment of his right to Lorraine for 400,000 pieces of gold, and led an army to Naples, but was obliged to leave the kingdom to his opponent and return in 1442 to Provence. Having restored order in Lorraine, he gave it over to his eldest son, John, titular duke of Calabria, and devoted himself to letters and the arts. In 1467 the Aragonese offered him the sovereignty of their country, which he declined for himself but accepted for his son, the duke of Calabria, who died soon after entering Aragon. The only companion of René's closing years was his exiled daughter, Queen Margaret of England, wife of Henry VI. King René was prominent as a patron of letters and the arts. Many paintings and pieces of sculpture were formerly attributed to his own hand, but have been shown to have been done only under his auspices. A considerable number of his writings still remain, the chief of which were edited by the count de Quatrebarbes, *Œuvres du roi René* (4 vols. 4to, Paris and Angers, 1845-'6). See also *Le Roi René, sa vie et ses travaux*, by De Lecoy de la Marche (Paris, 1875).

RENFREW, an E. county of Ontario, Canada, bounded N. E. by the Ottawa river above Ottawa; area, 2,389 sq. m.; pop. in 1871, 27,977, of whom 13,565 were of Irish, 6,147 of Scotch, 2,882 of French, 2,658 of English, and 2,318 of German origin or descent. It is intersected by the Bonnechere and Madawaska rivers. The surface is rough and hilly and the soil fertile. Capital, Pembroke.

RENFREWSHIRE, a W. county of Scotland, bounded N. by the river Clyde, and W. by the frith of Clyde; area, 254 sq. m.; pop. in 1871, 216,947. The chief towns are Paisley, Greenock, Renfrew, and Port Glasgow. The whole county is included in the basin of the Clyde, and its E. part is within the great coal district of the west of Scotland. Alum and iron are

produced in large quantities. The Stuart family had their earliest known patrimonial inheritance in the parish of Renfrew in this county.

RENI, Guido. See GUIDO RENI.

RENNELL, James, an English geographer, born near Chudleigh, Devonshire, Nov. 3, 1742, died in London, March 29, 1830. He entered the navy, served in India, became engineer in the East India company's service, distinguished himself in the campaigns of Lord Clive, and was made surveyor general of Bengal, returning to England in 1782. In 1795 he assisted Mungo Park in the preparations for his journey in Africa, and afterward contributed geographical illustrations to his travels. He was buried in Westminster abbey. The works by which Rennell is best known are "The Geographical System of Herodotus Examined and Explained" (4to, 1800), and "Observations on the Topography of the Plain of Troy" (4to, 1814). Among his other works are: an atlas of Bengal (1781), and a map of Hindostan, with an explanatory memoir (1783); "Elucidations of African Geography" (1793-'8); "Illustrations of the Expedition of the Younger Cyrus, and the Retreat of the Ten Thousand" (1816); "Comparative Geography of Western Asia" (1831); and "An Investigation of the Currents of the Atlantic Ocean" (1832).

RENNES, a fortified town of France, capital of the department of Ille-et-Vilaine, at the junction of the rivers Ille and Vilaine, 190 m. W. S. W. of Paris; pop. in 1872, 52,044. The court house is an ancient edifice, in which the estates of Brittany used to meet. There is a library of 45,000 volumes, and also a gallery of art. The town contains an academy with faculties of law, sciences, and literature, a secondary school of medicine, a theological seminary, and a normal college. Linen, woollen, leather, and pottery are manufactured. The Vilaine is navigable for barges, and canals lead to Brest, St. Malo, and Nantes.—The ancient name of the town was Condate, and the modern appellation of Rennes was derived from an Armorican tribe called by the Romans Redones. In the middle ages it was the capital of the Breton dukes, till it became united to France by the marriage of Anne of Brittany to Charles VIII. (See BRITANY.) It withstood several sieges, the most remarkable of which was that of the English under the duke of Lancaster (1356), who was obliged to retire after six months.

RENNET. See CHEESE, vol. iv., p. 349.

RENNIE, John, a British engineer, born at Phantassie, Haddingtonshire, June 7, 1761, died in London, Oct. 16, 1821. He learned the trade of a millwright, studied mathematics two years, settled in London in 1783, and engaged in the construction of steam engines and machinery. He planned and superintended the stone bridge at Kelso, below the junction of the Tweed and Teviot, the Waterloo and other bridges over the Thames at London, the Kennet and Avon canal from Bath

to Newbury, the London docks, the East and West India docks at Blackwall, the Plymouth breakwater, and many other great works.—GEORGE, his son (1791–1866), also a distinguished engineer, published "Experiments on the Strength of Materials," "The Frictions of Solids," and "The Frictions of Fluids." Sir JOHN (1794–1874), brother and partner of the preceding, knighted on the opening of the new London bridge in 1831, was the author of "The Theory, Formation, and Construction of British and Foreign Harbors" (2 vols. fol., 1854).

RENO, a S. county of Kansas, intersected in the N. E. corner by the Arkansas river, and watered by several of its affluents; area, 1,512 sq. m. It is not included in the census of 1870. Capital, Hutchinson.

RENOUARD, Antoine Augustin, a French bibliographer, born in Paris, Sept. 21, 1765, died at St. Valery, Dec. 15, 1853. He was originally a manufacturer of gases, but in 1797 became a bookseller and publisher in Paris, retiring in 1824. His principal works are: *Annales de l'imprimerie des Alde* (2 vols., 1803), which passed through several editions; *Annales de l'imprimerie des Estienne* (1837-'8; 2d ed., 1843); and valuable annotated catalogues.

RENSELAIR, an E. county of New York, bordering on Vermont and Massachusetts, bounded W. by the Hudson river, and drained by the Hoosick and Little Hoosick rivers, and Kinderhook creek; area, 690 sq. m.; pop. in 1870, 99,549. Two ranges of mountains, the Taghkanick and Petersburg, traverse it from N. to S.; they have an elevation of from 1,000 to 2,000 ft., with precipitous declivities, studded with numerous small lakes. The soil is generally hard and sterile, but much of it is under cultivation, yielding liberal crops. Several railroads pass through the county. The chief productions in 1870 were 5,527 bushels of wheat, 187,383 of rye, 211,968 of Indian corn, 717,845 of oats, 49,762 of buckwheat, 1,504,209 of potatoes, 108,214 tons of hay, 235,496 lbs. of wool, 1,271,128 of butter, 365,416 of cheese, 43,286 of hops, 774,773 of flax, and 54,513 of maple sugar. There were 9,372 horses, 16,813 milch cows, 1,358 working oxen, 8,585 other cattle, 54,928 sheep, and 9,276 swine. The county contained 792 manufacturing establishments, employing 15,588 hands, and having an invested capital of \$12,354,181, with annual products amounting to \$28,550,306. The principal manufactures are iron and iron ware of many kinds, agricultural implements, bells, cotton and woollen goods, brick, linen and paper collars, carriages and wagons, machinery, marble and stone work, flour, lumber, paper, and leather. Capital, Troy.

RENVILLE. I. A S. W. county of Minnesota, bounded S. W. by the Minnesota river, and drained by its branches; area, about 1,000 sq. m.; pop. in 1870, 3,219. The surface consists mostly of rolling prairies, and the soil is fertile. The chief productions in 1870 were 43,289

bushels of wheat, 6,537 of Indian corn, 27,659 of oats, 9,731 tons of hay, 1,735 lbs. of wool, and 40,185 of butter. There were 993 milch cows, 1,759 other cattle, 833 sheep, and 285 swine. Capital, Beaver Falls. **II.** A N. W. county of Dakota, bordering on British America, recently formed, and not included in the census of 1870; area, about 1,800 sq. m. The S. W. part is occupied by the Plateau du Coteau du Missouri; the rest is watered by Mouse river. The surface is generally undulating, and the county is well adapted for grazing.

RENEWICK. **I.** James, an American physicist, born in New York in 1792, died there, Jan. 12, 1863. He graduated at Columbia college in 1809, was professor of chemistry and physics there from 1820 to 1854, and in 1838 was appointed one of the commissioners to explore the N. E. boundary between the United States and New Brunswick. He was the author of "Outlines of Natural Philosophy" (2 vols. 8vo, New York, 1822-'3), the earliest extended work on that subject published in the United States; "Treatise on the Steam Engine" (8vo, 1830), translated into several languages; "Elements of Mechanics" (8vo, Philadelphia, 1832); and "Applications of the Science of Mechanics to Practical Purposes" (12mo, New York, 1840). He privately printed for the use of his classes "First Principles of Chemistry" and "Outlines of Geology" (1838), the latter preceding by several years any other school treatise on the subject. **II.** James, an American architect, son of the preceding, born in New York in 1819. He graduated at Columbia college in 1836, was an engineer on the Erie railway and the Croton aqueduct for about five years, and superintended the construction of the distributing reservoir. At the age of 23 he won in competition the commission for the building of Grace church, in Broadway, and has since built the new St. Patrick's cathedral in New York, Calvary church, the second Presbyterian church, the Smithsonian institution in Washington, various hospitals on Blackwell's, Ward's, and Randall's islands, and Vassar college.

REPLEVIN (law Lat. *re*, back, and *plegium*, pledge), a redelivery of a thing to the owner, upon pledges or security; the taking from some holder property which the taker claims, he giving back pledges to establish his right, or, if he fails in this, to return the property. The institution of this very important action is ascribed to Glanvil, chief justice to Henry II.; and it was originally the peculiar and exclusive remedy in cases of wrongful distress. The object was to prevent the beasts of the plough, cattle, and other goods of the tenant in arrear from being unjustly or excessively distrained by the landlord, lest, as Littleton observes, "the husbandry of the realm and men's other trades might thereby be overthrown or hindered." At the common law a distress (which implies both the thing taken and the manner of taking it) was considered merely as a pledge

or security for the rent, for damage feasant, or for service due from the tenant to his superior lord, and a means of enforcing its payment or performance. It could not be sold or disposed of by the distrainor, but he was compelled to hold it as a pledge until payment or other satisfaction was made. For this reason beasts of the plough and the tools of a man's trade could not be distrained, lest by depriving him of these he should also be deprived of the ability to redeem them; but the statute 2 William and Mary, 1, c. 5, authorized the distrainor, with the assistance of the sheriff, to have the distress appraised by competent appraisers, and sold for the highest price which it would bring, unless regularly replevied by the tenant or owner within five days after seizure. There were two ways in which a distress could be replevied, one according to the common law, and the other by a statute. The common law allowed the owner a writ *de replegiari facias*, which was sued out of the court of chancery and directed to the sheriff of the county in which the distress was taken, commanding him to redeliver it to the owner upon receiving sufficient sureties therefor, and afterward to determine the ownership and do justice as to the matter in dispute between the parties, in his county court. The statute of Marlbridge, on the other hand (52 Henry III., c. 21), provided that, without suing out a writ, the sheriff or any of his deputies (of whom four were appointed in each county for the express purpose of making replevins) should, immediately upon complaint being made to him, proceed to replevy the goods. The owner was then obliged to give satisfactory security to two ends: first, *plegios de proseguendo*, or pledges to prosecute his suit to final judgment; and second, *plegios de retorno habendo*, or pledges to return the distress again to the distrainor, if the right should be determined against him. These pledges were discretionary, and the sheriff was responsible for their sufficiency; and in addition to them the statute required a bond with two sureties for double the value of the goods taken, also conditioned to prosecute the suit and return the goods. This bond was to be assigned to the avowant or person making cognizance, on request to the officer, and if forfeited it could be sued by the assignee. If the sheriff neglected to take a bond, or if he accepted insufficient pledges, the party might have an action against him and recover double the value of the goods distrained, but no more. The owner of goods distrained might replevy them although his grant by deed contained a special condition that the distress should be irreplevisable, and that the landlord should keep it as a gage or pledge until the rent were paid; because it was held to be incompatible with the nature of a distress that it should be irreplevisable. The sheriff, on receiving the required security, was at once to cause the distress to be returned to the party from whom

it was taken, unless the distrainer himself claimed the goods as his property; for if they were, the law permitted him to keep them, irrespective of the manner in which he had regained possession. If therefore the distrainer claimed any such right or property, the party replevying was obliged to sue out another writ called a writ *de proprietate probanda*, by which the sheriff was to determine, by an inquest, who was really the owner of the property before the distress was levied thereon. If it was decided against the claim of the distrainer, the sheriff proceeded to replevy as if no such claim had been made; but if his claim was found to be good and valid, the sheriff could proceed no further, but was to return the claim to the court of king's bench or common pleas, to be there prosecuted and finally decided. The goods, in ordinary cases, being delivered back by the sheriff to the party replevying, he was then compelled to prosecute his suit or action of replevin in the county court, though either party might remove it to the superior court of king's bench or common pleas; and indeed, to save trouble and delay, it was usually carried up in the first instance to the courts of Westminster hall, because if, in the course of proceeding in the county court, any right of freehold came in question, the sheriff could proceed no further. Upon action being brought, the distrainer, who was now the defendant, made avowry; that is, he avowed taking the distress, and set forth the right in which and the cause for which he took it, as for rent in arrears, damage done, or other cause; or if he justified in another's right, as bailiff or servant, he was said to make cognizance; that is, he acknowledged the taking, and claimed that it was legal as being done at the command of one who had a right to levy the distress; and upon the legal merits of this avowry or cognizance the cause was determined. If the action was decided in favor of the plaintiff, and the distress declared to be wrongful, he was entitled to keep the goods which he had already got back into his possession, and in addition should recover damages for the wrongful seizure and detention; but if the defendant prevailed, he should have a writ *de retorno habendo*, by which the distress was returned into his possession irreplevisable, to be sold or otherwise disposed of, as if it had never been replevied. If the debtor had in the mean time disposed of or concealed the distress, so that it could not be found, execution issued against his other goods, and for want of them against his body in the nature of a writ of *capias*. While distresses continued to be held as mere pledges, if the former owner, after judgment against him, offered the distrainer the arrearages or other damages due, and he refused thereupon to deliver up the distress, the plaintiff might bring an action of detinue, and by that means recover its possession. If, while a replevin for a former distress was pending, a man distrained again for the same rent or service, the party

was not obliged to bring another action of replevin for the second distress, but could have a writ of recaption and recover the goods with damages for the distrainer's contempt of the process of the law.—Formerly a mere possessory right was not sufficient to entitle a party to maintain replevin; but now it is sufficient if the plaintiff can prove a general or special property in the goods, with the right of immediate and exclusive possession, either as mortgagee, owner, agent, or bailee, without actually having such possession at the time. Though replevin was formerly confined to cases of wrongful distress, it is now the proper form of action by which to recover the specific thing taken, in all cases where goods have been tortiously taken or detained, whether by distress or in any other manner, together with damages for the detention, unless the taking and detention can be justified or excused; and it is one of the most important and frequently used modes of legal remedy. The forms and manner of proceeding, with some slight alterations, remain the same now as formerly, as far as the redelivery of the goods to the party claiming them, the giving of bonds with sureties in double the value of the goods, the prosecution of the action, and the final judgment and execution are concerned. This action will lie for goods taken in execution, provided the person bringing it against the officer who takes the goods from another by virtue of the execution has a property, general or special, in them, and a right to reduce them into his actual possession; but no replevin will lie in favor of the defendant in execution or attachment, unless the goods seized are exempted by law from being so taken. In some cases replevin for property taken for taxes is forbidden.

REPOUSSÉ. See supplement.

REPTILES (Lat. sing. *reptilis*, from *reperere*, to creep), a class of vertebrated animals intermediate between fishes and birds. Linnæus united the oviparous quadrupeds and the serpents of Aristotle under the erroneous name of *amphibia*; until within a recent period batrachians, as well as serpents, lizards, and tortoises, were included among reptiles, but now the first are regarded as a distinct class. As thus limited, reptiles do not undergo metamorphosis, are always air breathers, though cold-blooded, and have neither mammæ, hair, nor feathers. By the first two peculiarities they are distinguished from fishes and batrachians, and by the third from mammals and birds. Although they breathe air by lungs like birds and mammals, the pulmonary circulation is incomplete, only a part of the blood being sent to them, and, from the communication of the ventricles of the heart or the great vessels, a mixed arterial and venous blood, principally the latter, is sent to the organs. Reptiles have been divided into chelonians or tortoises, saurians or lizards, and ophidians or serpents, whose characters are given under their respective orders, families, and popular names. The various sys-

tems of classification will be found under HERPETOLOGY; the batrachians have been treated under AMPHIBIA, and the anatomical peculiarities of the order under COMPARATIVE ANATOMY. The number of species of reptiles is about 2,000, or less than that of mammals or birds; most of them are terrestrial, but some (as the dragons) can sustain themselves in the air like the flying squirrels, and the extinct pterodactyl probably winged its way like the bats; some live habitually in the water, swimming by means of flattened fins (as the turtles), or by a laterally compressed tail (as in crocodilians); the amphibana and other ophisaurians dwell in subterranean burrows. They present every degree of speed, from the agility of the lizard to the slowness of the tortoise; some are fitted for running over dry sand, others for climbing trees, others for ascending smooth surfaces; the limbs are not generally adapted for rapid or graceful motions, being short, almost at right angles with the spine, and hardly raising the body during locomotion enough to prevent the ventral surface from dragging on the ground; the anterior limbs are the shortest, and the knees and elbows are constantly flexed and far apart longitudinally; the feet are not adapted for prehension (the chameleon excepted), so that they display little skill in preparing retreats for themselves or places for their eggs. They are naturally cold-blooded for reasons given below, and are found in greatest abundance and of largest size in warm climates; under the influence of cold they pass into a lethargic state, and according to Humboldt a similar condition befalls the South American crocodilians during the hottest season of the equatorial regions. The tortoise and the crocodile are sufficiently protected against ordinary enemies; the lizard darts into its hole, perhaps at the expense of a part of its tail, which is soon reproduced; the great boas prevail over every foe but man; many serpents are armed with poisonous fangs, rarely used however except on the defensive; some are covered with bristling spines, like the horned lizards, and are thus saved from predaceous animals. They are of great use to man in destroying noxious insects and other animals; some, like the chelonians, furnish a wholesome and abundant food, and others supply various articles useful in the arts. They are preyed upon by carnivorous birds, as eagles, storks, cranes, and the ibis, and by such mammals as the ichneumon, hog, and the smaller carnivora; they are themselves essentially carnivorous, and feed on living prey which they swallow whole, but the marine turtles are principally herbivorous.—The osteology of reptiles has been given sufficiently in the various articles above referred to. Except in chelonians, the form is generally elongated, more or less cylindrical, with a very long tail; the feet are absent in serpents and in some saurians, and four in the others; the skeleton is always osseous, the cranium small,

and the facial bones and jaws greatly developed, the latter usually armed with sharp, hooked teeth; the toes are freely movable, and usually with strong claws, webbed in the crocodiles and turtles. The body is covered with scales, generally appendages of the true skin; the overlying epidermis is cast off periodically; the scales are converted into bony plates in the chelonians and crocodiles, and in lizards and serpents are often brilliant with metallic reflections; in the chameleon, anolis, &c., the surface modifications of the skin present very rapid changes of color, sometimes expressing the anger or fear of the animal, and in some cases enabling them to avoid detection by their enemies. The muscles of reptiles are red, though paler than in mammals and birds; they preserve their irritability for a long time after the death of the animal, in chelonians even after many days; tortoises have been known to live for 18 days after the removal of the brain, groping blindly about. The brain is small, with cerebrum, cerebellum, and medulla oblongata; they have also a spinal system of nerves, and a sympathetic or ganglionic chain; in most the spinal marrow is relatively much more developed than the brain, the latter being smooth, without convolutions, the cerebral lobes being the largest; the cerebral hemispheres contain lateral ventricles, and are larger than the optic lobes, which in fishes constitute the greater part of the brain; there is no *pons Varolii*, and the cerebellum is more developed than in fishes. Life seems in a remarkable degree independent of the brain, the class rather vegetating than living, and being comparatively insensible to pain; they grow slowly and live long, and are exceedingly tenacious of life; the intelligence is hardly greater than in fishes. The sense of touch is dull, both active and passive, and whether exercised by the skin, toes, lips, tongue, or tail; taste must also be dull, as the food is swallowed without mastication, and the sense of smell must be still less. The organ of hearing is less developed than in birds and mammals; there is no external ear; the tympanum, where it exists, is bare and almost external, and the internal ear is less developed than in fishes. The eyes are usually small, occasionally absent, flat, with incomplete bony orbits, with lids (except in serpents), and with lachrymal glands. The nasal cavities are large, and always communicate with the mouth, and in the crocodiles are very far back. The lungs are sometimes large, extending even through the whole length of the ventral cavity, which has no diaphragm; in the long-bodied snakes only one lung is active, the other being very rudimentary or absent; these organs are comparatively free, the trachea not divided into bronchi, and the air cells few, large, and freely communicating with each other; in lizards and serpents the ribs serve for respiration, and in tortoises the scapular arch performs the office of ribs, according to Van der Hoeven, respiration not

being effected by deglutition. Only a small portion of the blood is sent to the lungs, and this is feebly oxygenated, as the respiration is performed slowly and the lung is of loose texture and small capacity; hence a low degree of animal heat, languid movements, and a slow performance of the nutritive functions. They have no true epiglottis and no proper voice, though some emit a hissing sound (as the ophidians) formed in the mouth. The heart has four cavities, but the ventricles communicate, except in the crocodilians, where an admixture of the arterial and venous bloods takes place in the great vessels; there is, therefore, a partial circulation independent of respiration, enabling them to remain long under water and in irrespirable gases. The lymphatic system is greatly developed, having regular pulsating organs or lymphatic hearts for the propulsion of their fluid. Reptiles eat and drink comparatively little, and are able to go a long time without food; not having movable and fleshy lips, they cannot perform the act of suction, as was once popularly believed of serpents; the mouth is generally large, and the lower jaw articulated by a distinct bone, the homologue of the *os quadratum* of birds. The tongue is generally free, and the œsophagus very wide and distensible to accommodate large prey; the intestine is short and straight in proportion to the carnivorous disposition, being longest in the herbivorous chelonians and shortest in the snakes; there is a certain division into small and large intestine, though the latter in most is properly the rectum; the alimentary canal opens below into a cloaca, or cavity common to the digestive, urinary, and reproductive organs, as in birds; all the nutritive elements are extracted from the food, the indigestible matters being ejected in a mass at long intervals; the vent is transverse in snakes and lizards, but longitudinal in chelonians and crocodiles, corresponding to remarkable differences in the male external reproductive organs, these in the former being double and placed in a cavity behind the anus, and in the latter single and within the cloaca. Salivary glands, which are absent in fishes and batrachians, are present in reptiles; the liver is always present and large, receiving much venous blood, especially that from the posterior part of the body; the gall bladder is commonly found, though small; the spleen is generally very small, removed from the liver and stomach, rounded, and deep red; the pancreas is constant, often large at the beginning of the intestine, and of various forms; the kidneys are situated along the spine, showing no distinction of cortical and medullary portions; the ureters open into the cloaca, and the urine is a whitish mass, more or less hard, containing salts of lime and ammonia; the supra-renal capsules are usually present, small, and often remote from the kidneys; there are one posterior and two anterior venæ cavae. The power of reproducing lost parts is less than in batra-

chians, and is noticed especially in the tails of certain lizards and serpents. In this class there is no durable union of the sexes as in birds and mammals, and nothing which exerts any influence on the social condition of the individuals; after the instinctive act of reproduction they separate and become perfect strangers. Most are oviparous, leaving their eggs to be hatched by the heat of the sun, and the young when born are able to provide for themselves and are generally indifferent to the mother; the female rarely makes a nest, but deposits her eggs in a safe, warm, and dry place; crocodiles and some lizards watch in the neighborhood of the place where their eggs are concealed, and the python has been seen in menageries coiling herself around her eggs in a conical form, closing the top with her head. Some of the serpents are viviparous, the young being so far developed before the exclusion of the eggs as to be born alive; in the viviparous snakes the young are said to take refuge within the mouth of the mother. The eggs have generally a more or less calcareous shell, globular or rounded equally at each end; in serpents they are often joined together in chaplets; their number varies from 20 to 100. The embryo is completely enveloped by the amnios, and after it has attained a considerable degree of development a second membranous covering appears, for the first time in vertebrates, the allantois, richly supplied with vessels and enclosing embryo and amnios.—As reptiles are generally despised and hated by man, and comparatively little under his influence, their original geographical distribution has been but slightly changed by him. Most of the serpents, especially the venomous kinds, belong to warm regions.—The secondary geological epoch, comprising the trias, Jurassic, and chalk, has been called the age of reptiles; during this period air-breathing animals first appeared in considerable numbers, and reptilian forms predominated. Reptiles are connected with birds, especially those of the former called *symphy-poda* by Cope; dinosaurians, progressing by leaps, with very small anterior limbs, have made many of the bird-like tracks described by Hitchcock in the sandstone of the Connecticut valley. The gigantic and uncouth forms of the secondary age had disappeared in the tertiary, and the reptiles of the latter were more like the present ones, except in geographical distribution, and were in about the same proportion to the rest of creation as now. The study of fossil reptiles shows the limited duration of species; before the diluvial epoch there is not a single reptile that can be referred to living species and hardly to an existing genus; the reptiles of each age, triassic, Jurassic, and cretaceous, have a special facies, unlike any which preceded or followed them; the difference between the fossil and living forms is always greater as we go back in time. This study also proves that the temperature of the earth has varied, as the great reptiles above named

lived in parts of Europe nearer the frigid than the torrid zone. All the fossil forms, however odd, were constructed on the same reptilian vertebrate type as at present, in some instances with ornithic (pterodactyl) or mammalian affinities (ichthyosaurus). In the most ancient fauna of reptiles, chelonians and saurians, the highest in the class, are represented, and some forms then existing were in certain respects more perfect, or at any rate more complex, than some present members of the class; each fauna had its type of perfection, without regard to the superiority or inferiority of that which preceded or followed it; we find no transition species leading to or from ichthyosaurus, plesiosaurus, pterodactyl, and the like, unless we ascend to cetacean mammals in the first and to bats in the last. Reptiles (including batrachians even) are very rare, and to some questionable, in the Devonian; there are a few amphibians in the carboniferous; the class abounds in the divisions of the trias, and is most numerous in the Jurassic, becoming less abundant in the oolite and chalk. For details on fossil reptiles see the various articles on the genera above mentioned. Professors Cope and Marsh have described several new forms of reptiles from the western territories, in the "American Naturalist," "Proceedings of the Academy of Natural Sciences," Philadelphia, and the "American Journal of Science."

REPTON, Humphry, an English landscape gardener, born in Bury St. Edmund's, May 2, 1752, died in Essex, March 24, 1818. Having failed in mercantile business, he adopted the profession of landscape gardening, and was henceforth uninterruptedly prosperous. At the period of his death there was scarcely a county in England which did not have some "places" adorned by his skill. His works on landscape gardening, with an account of the author's life, were reprinted by J. C. Loudon (8vo, 1840).

REPUBLIC, a N. county of Kansas, bordering on Nebraska, and intersected by the Republican river; area, 720 sq. m.; pop. in 1870, 1,281. It has an undulating prairie surface. The chief productions in 1870 were 8,626 bushels of wheat, 16,820 of Indian corn, 4,705 of potatoes, 13,790 lbs. of butter, and 1,079 tons of hay. There were 463 horses, 1,039 cattle, 325 sheep, and 181 swine. Capital, Belleville.

REPUBLICAN RIVER. See KANSAS, vol. ix., p. 747.

RESACA DE LA PALMA, a ravine, as its name imports, thickly grown with palm trees, that crosses the Matamoros road, in Texas, about 3 m. from the place where the road opens upon the Rio Grande opposite Matamoros. In a battle fought here, May 9, 1846, 2,000 United States troops under Gen. Zachary Taylor defeated 6,000 Mexicans under Gen. Arista.

RESHID PASHA, Mustapha Mehemed, a Turkish statesman, born in Constantinople in 1802, died there, Jan. 7, 1858. He was educated by Ali Pasha, who had married his sister, and was

governor of a province in Asia Minor. When Ali as grand vizier was sent to suppress the Greek insurrection in 1822, Reshid accompanied him; and in the campaign against the Russians in 1828-'9 he was private secretary to Selim Pasha. He took part in the negotiation of the treaty of Adrianople, and was sent on a diplomatic mission to Mehemet Ali, pasha of Egypt. In 1833 he assisted in negotiating the treaty of Kutaieh. In 1837 he became minister of foreign affairs, but held the post only for a year, going as special envoy to London and Paris. In 1839, after the reopening of the Egyptian war, he was recalled by Sultan Abdul-Medjid, who had succeeded Mahmoud II., to take charge again of the foreign ministry. He caused the promulgation of the *hatti-sherif* of Gulhane, raising the Christians to a civil equality with the Mussulmans, and brought about the quadruple alliance by which Egypt was compelled to evacuate the Turkish provinces. In 1841 he was again envoy to England and France. He was made grand vizier in 1846, but lost his post six years later, and retired to private life, only to be recalled very soon to his high office, which he was compelled to resign in 1857 through an illness that shortly proved fatal. His influence was always exerted for the maintenance of peace. He discountenanced polygamy, and was distinguished for his literary and scientific attainments.

RESHT, or **Reshd**, a city of Persia, capital of the province of Ghilan, about 5 m. inland from the bay of Murd-ab or Enzeli in the Caspian sea, and 142 m. N. W. of Teheran; pop. about 20,000. It is well paved, and the houses are uncommonly neat and of superior construction. There are extensive bazaars, and a large trade is carried on in raw silk, embroideries, fruits, and fish. It has of late greatly decreased in importance and population, partly from frequent visitations of cholera. The population embraces Persians, Russians, Turks, Armenians, Jews, and Hindoos, and the streets and bazaars swarm with fakirs, dervishes, and other mendicants. Enzeli, at the entrance of the gulf of Murd-ab, is its port, but the sea is there so boisterous and the surf so high that the steamers plying between Astrabad and Baku are at times not able to land their passengers. Treaties of peace between Persia and Russia were signed at Resht in 1729 and 1732.

RESINA (anc. *Retina*), a town of Italy, in the province, on the gulf, and 6 m. S. E. of the city of Naples, at the W. base of Vesuvius; pop. about 12,000. It covers a large part of the ruins of Herculaneum, and the sinking of a well here in 1709 led to the excavation of relics and to the first discovery of the real site of the latter city. Resina is the place from which the ascent of Vesuvius is generally made, and has many villas, which extend almost to the neighboring Portici. The most celebrated of these is the villa La Favorita, built on the lava of 1631, and formerly belonging to the prince of Salerno. Silk is woven

to some extent, and the renowned *Lacrymæ Christi* wine is produced in the vicinity. The ancient *Retina* was supposed to have been a naval station and the port of *Herculeaneum*.

RESINS, a class of proximate principles existing in almost all plants, and appearing upon the external surface of many of them in the form of exudations; also the oxidized and concentrated juice of several species of coniferous and other trees. They are produced by certain families in considerable abundance, and in smaller quantities by a very large number of plants. When not exuding spontaneously, they often escape from punctures in the bark made by insects, or may be obtained by making incisions into the wood. They appear in the form of a viscid liquid consisting of the resin in solution in the essential oil of the plant. (See **BALSAMS**, and **TURPENTINE**.) It is possible that the resins never exist as such in plants, but it is certain that in the majority of cases they are formed by the oxidation of the essential oils contained in the plants. They are sometimes extracted by boiling the sawdust of the wood with alcohol, from which they are precipitated by the addition of water, and as the alcohol is distilled off the particles agglomerate. Resins are so variously composed of numerous principles, that no little diversity is observed in their general properties, and they are therefore arranged by different authorities under several heads. 1. Resins which exude spontaneously from plants, or from incisions in the stems and branches, and harden on exposure to air; these sometimes contain considerable quantities of gum or mucilage (gum resins), or of volatile oil (balsams). This class includes: *a*, resins containing benzoic or cinnamic acid, such as benzoin, storax, and balsam of Peru or tolu; and *b*, resins not containing those acids, such as *asafetida*, *copaiba*, *copal*, *jalap*, *lac*, *mastic*, and common *turpentine*. 2. Oxidized fossil resins, such as *amber*, and others occurring in beds of coal or lignite. 3. Resins extracted from plants by alcohol, such as the resins of *cubebs*, *buchu*, and *squills*. In general the resins are solid bodies of vitreous fracture, and brittle, so as to be readily pulverized when cold. Others are soft and greasy, and some are elastic. They are usually transparent or translucent, rarely colorless, but either brown, red, or green. Their specific gravity is from 0.92 to 1.2. They occasionally have a decided taste or odor, derived from some essential oil or other foreign substance present; and to the same cause is probably owing the occurrence of some of the resins in a soft state. The solid resins are non-conductors of electricity, and by friction they assume the electric state known as negative or resinous. They melt at a moderate heat, and form a thick viscid liquid; on cooling this becomes a shining solid mass of vitreous fracture, which occasionally, when scratched with a sharp point after sudden cooling, flies off into pieces like *Prince Rupert's drops*. They readily take fire, and

burn with a white or yellow flame and much sooty smoke. Some are soluble in ether, and others in volatile oils, boiling alcohol, or fixed oils with the aid of heat. The alcoholic solutions of some of them possess acid properties; others are neutral. These acid resins combine with the alkalies and form lyes, which when agitated produce a lather like that of soap, differing from it, however, in not being precipitated or becoming hard on addition of common salt. (See **ROSIN**.) Many of the natural resins are mixtures of two or more resins, which may often be separated from each other through their different solvents. When decomposed at a high heat in close vessels, the resins are resolved into carbonic acid, different gaseous hydrocarbons, empyreumatic oil, a little acidulous water, and a very little shining charcoal.—Chemically the resins consist of carbon, hydrogen, and oxygen, often in such proportions as to indicate a product of the oxidation of a multiple of C_6H_8 . As they slowly absorb oxygen, with or without evolution of carbonic acid or water, or both, they are very unstable. Very few can be crystallized, and hence it is only with extreme difficulty that they can be obtained in a condition of purity. In the case of gamboge, myrrh, and others less frequently met, an atom of oxygen appears to be substituted for two atoms of hydrogen in the essential oil; but mastic, elemi, and others appear not only to exchange hydrogen for oxygen, but also to take up water. Some of them may therefore be considered to be oxides and others hydrates of the essential oils. As the resins have not yet been formed artificially from the essential oils, these views have not been proved correct.—Solutions of resins in alcohol, oil of turpentine, and fixed drying oils form varnishes. Spirit varnishes are at the same time the most brilliant and the most brittle; their elasticity may be increased by the addition of oil of turpentine. The resins commonly used for varnishes are copal, elemi, lac, mastic, and sandarach.

RESPIRATION (Lat. *respirare*, to breathe), the function by which oxygen is absorbed by the living organism for the maintenance of vitality, and by which carbonic acid is discharged as a product of disintegration or waste of the materials of the tissues. Respiration in some form is common to all living beings. Even in vegetables none of the more active phenomena of life can go on unless the plant be constantly supplied with oxygen; and the intensity with which these phenomena are manifested is in proportion to the rapidity with which oxygen is absorbed by its tissues and carbonic acid exhaled. In animals the process of respiration is still more marked; and it is more active in the warm-blooded birds and mammalia than in the cold-blooded reptiles and fishes. Animals which inhabit the water and breathe by gills absorb through them the oxygen which is in solution in water, and discharge carbonic acid by the same

channel. In man and the air-breathing animals, the atmospheric air, which consists of 21 volumes of oxygen mixed with 79 volumes of nitrogen, is drawn by the movement of inspiration into the lungs, and discharged by the movement of expiration. During its stay in the pulmonary cavities it is changed in composition. The first and most important change is a diminution of its oxygen. As a general rule, the air loses in this way, by the effect of a single respiration, 5 per cent. of its volume in oxygen. As, on the average, 20 cubic inches of air are taken into and discharged from the lungs by each respiratory act, the quantity of oxygen thus removed from the air at each respiration is one cubic inch. The movements of respiration follow each other usually at the rate of 18 or 20 a minute, and are accelerated by any active muscular exertion. The total quantity of air thus used for respiration in 24 hours is not far from 350 cubic feet; and accordingly the daily quantity of oxygen taken from the air and consumed by a healthy adult man is about $17\frac{1}{2}$ cubic feet, or more than four times the volume of the whole body. The amount of carbonic acid given off at each respiration in man is rather less than one cubic inch. The expired air usually contains about 4 per cent. of its volume of carbonic acid; this amounts, under ordinary circumstances, to about 14 cubic feet a day. Although the volume of the carbonic acid exhaled is less than that of the oxygen absorbed, its weight is considerably greater; the whole amount of oxygen consumed during 24 hours being about 10,000 grains, or rather less than $1\frac{1}{2}$ lb. avoirdupois, while that of carbonic acid exhaled during the same time is over 11,000 grains, or rather more than $1\frac{1}{2}$ lb. A certain amount of watery vapor is discharged with the expired breath. This vapor is invisible at moderately warm temperatures, since it is then in the completely gaseous form; but if it be cooled below a certain point, as by coming in contact with cold air or cold metallic or glass surfaces, it becomes condensed, and is then rendered visible as a cloudy vapor or as a deposit of moisture. The amount of watery vapor thus discharged with the breath during 24 hours is, on the average, rather more than one pound avoirdupois. The oxygen absorbed from the air in the lungs is taken up by the blood, and carried away in the arterial circulation. At the same time the blood loses the dark purple color which it presents before entering the lungs, and assumes a bright scarlet hue. This process is the most immediate effect and the main purpose of respiration, and constitutes the principal distinction between arterial and venous blood. Venous blood is dark because it is deficient in oxygen; arterial blood is bright red because it contains an abundant supply of this necessary ingredient. The brilliant color of arterial blood is therefore an indication that it has absorbed its requisite quantity of oxygen, and is fit to provide for

the stimulus and nutrition of the tissues. As the arterial blood is disseminated throughout the body and comes in contact with the substance of the tissues, it gives up to them its oxygen and resumes a dark purple hue; it is thus reconverted into venous blood. At the same time it absorbs from the tissues a certain proportion of carbon, which has been set free in their substance, and, loaded with this product of disintegration, it returns to the right side of the heart, to be thence distributed to the lungs. There are accordingly two opposite and complementary changes taking place in the blood, during its passage through the lungs and the tissues respectively.—Since the air by respiration is deprived of a portion of its oxygen and loaded with carbonic acid, it will be incapable of supporting respiration continuously, unless renovated as rapidly as it is consumed. This renovation is provided for by the alternate movements of inspiration and expiration, by which the air already in the lungs, which has given up its oxygen to the blood and become mingled with carbonic acid, is discharged externally and replaced by a fresh supply. The expired air is at once disseminated in the external atmosphere and carried away by the currents which are always in motion; so that, while in the open air, the lungs are constantly supplied with the materials of respiration in a state of purity. But if respiration be carried on in a confined space, the oxygen of the air gradually diminishes in quantity, and carbonic acid accumulates in a corresponding degree. The air is thus at the same time impoverished and vitiated, and after a time its deterioration becomes so marked that it is no longer capable of supporting life. Air is completely unfit for respiration when its natural proportion of oxygen has been reduced one half, and when it has become contaminated with carbonic acid to the extent of one fifth of its volume. But although the most serious results follow when the air has been vitiated to this extent, a much smaller amount of deterioration is unwholesome. This is of the greater importance because, besides its loss in oxygen and its mixture with carbonic acid, the air in respiration is also contaminated by certain organic vapors which may be distinguished by their odor, and which are exhaled in the breath at the same time with the carbonic acid.

RESTIGOUCHE, a N. county of New Brunswick, Canada, bordering on Quebec and the bay of Chaleurs; area, 2,889 sq. m.; pop. in 1871, 5,575, of whom 2,695 were of Scotch, 1,143 of French, 1,133 of Irish, and 483 of English origin or descent. It is intersected by branches of the Restigouche river, which partly separates it from Quebec. The surface is diversified with mountains and valleys. The soil is well timbered; large quantities of timber are exported. Capital, Dalhousie.

RESTIGOUCHE, a river of Canada, rising in Madawaska co., in the N. W. part of New

Brunswick. It flows N. E. to the mouth of the Mistouche, and thence a little N. of E., forming the boundary between New Brunswick and Quebec, to the bay of Chaleurs, which it enters at Dalhousie, N. B. It is 3 m. wide at its mouth, and is navigable by the largest ships for 18 m. to Campbellton, N. B. The scenery along its course is grand and beautiful. With its tributaries it drains an area of about 5,000 sq. m. of fertile and well timbered country. It abounds in salmon. Its chief tributaries are the Wetomkegewick, Mistouche, and Matapediac from the north, and the Upsalquitch from the south.

RETHEL, Alfred, a German painter, born in Aix-la-Chapelle in 1816, died in Düsseldorf, Dec. 1, 1859. He studied under Schadow and Veit, visited Italy, and became insane in 1852. His principal works are the frescoes illustrating the history of Charlemagne in the town hall of Aix-la-Chapelle, his designs of "Hannibal crossing the Alps," and those of the "Dance of Death." His large cartoons of "Charlemagne at the Council of Frankfort" and "The embassy of the Caliph Haroun al-Rashid to Charlemagne" are at Düsseldorf.

RETINA. See EYE.

RETINISPORA (Gr. *ῥηίνη*, resin, and *σπορά*, seed), a name proposed by Siebold and Zuccarini in their *Flora Japonica* for a genus of *conifera*, which has been accepted until within a few years; but it has since been shown that the resinous coating of the seed, all that distinguishes it from *cupressus*, is found on undoubted species of that genus; hence it follows that the *retinisporas* cannot be kept distinct from the *cypresses*. As it is very difficult to supersede an established name, no doubt these Japanese species, having been introduced as *retinisporas*, will long retain that name in the catalogues and among arboriculturists. For their botanical characters, see *CYPRESS*. The species and varieties, though of comparatively recent introduction, have proved especially suited to the climate of the northern states. In Japan they are 100 ft. or more high, but in our gardens they are thus far only 1 to 6 or 8 ft. high. Like the *arborvitæ* and related plants, the foliage assumes very distinct forms, according to the age of the tree; and some good observers are disposed to regard the 15 or 20 named sorts of our gardens as all forms of a single species. For small places, these plants are especially valuable; they naturally assume a good form, and may be cut into any desired shape; they are generally upright, but there is one positively pendulous; some have the leaves small, blunt, and scale-like, others sharp and spreading; there are the darkest greens, and varieties with silver and golden variegation, and a collection of these forms presents wide contrasts in habit and color. The plants are for the most part propagated readily from cuttings; these are taken in the autumn, set in sand at a greenhouse temperature all winter, and as the heat increases in

spring root rapidly. The leading varieties are here enumerated by the names given in the catalogues, without reference to botanical accuracy. *Retinispora obtusa* has very dark green, small, blunt, appressed leaves, and there are several varieties. *R. pisifera* is more slender, and has a golden and silver variety. *R. ericoides* is a handsome heath-like plant. *R. lycopodioides* is much like a club moss. *R. filicoides* has fern-like branches. *R. plumosa* is one of the most valued of all, remarkably compact, with very numerous small branchlets which give the tree a plume-like appearance; the golden variety of this, *R. plumosa*, var. *aurea*, is of great beauty, and is destined to be one of the most popular of all conifers; it has the plumose habit of the green form, but the branchlets and all the spray are of a bright golden hue, and hold this color during the winter months; being easily propagated, it may be used for edgings and for a great variety of ornamental planting.

Plumy Retinispora (*Retinispora plumosa*).

RETORT. See DISTILLATION, and GAS.

RETRIEVER, a name given to several breeds of sporting dogs, from their being taught to retrieve or recover game which has fallen be-

Retriever.

yond the reach of the sportsman, or where he does not choose to go for it. The largest and best known is a cross between the Newfound-

land dog and the setter, best for game as large as a hare or pheasant; it stands nearly 2 ft. high, with powerful frame and stout limbs; the hair is moderately long and curly, and should be black; the sense of smell is very acute. They are very difficult to train. The smaller retrievers are a cross between the water spaniel or beagle and the terrier, smooth English or rough Scotch; they are less noisy and more companionable than the larger breed.

RETZ, Gilles de Laval, seigneur de, marshal of France, born about 1396, put to death in 1440. Under Charles VII. he distinguished himself in the war against the English, and fought at the side of the maid of Orleans. Money troubles obliged him to retire to his castle near Nantes. In consequence of rumors of shameful deeds practised by him, the bishop of Nantes summoned him to be tried before a mixed commission. It was proved that during 14 years the seigneur de Retz had enticed into his castle several hundred children, had practised magic, and had paid worship to the devil, in which his victims were obliged to take part as priests and priestesses. He was handed over to the civil power, and by a decree of Oct. 25, 1440, he was condemned to the stake, but, as a noble, was strangled.

RETZ, Jean François Paul de Gondl, cardinal de, a French politician, born at Montmirail in 1614, died in Paris, Aug. 24, 1679. He was a younger son of Philippe Emmanuel de Gondi, the general of the galleys under the reign of Louis XIII., and was intended for the church; but, with the design of establishing a reputation that would debar him from that employment, he entered on a career of intrigue and licentiousness, participating in every conspiracy against Richelieu. His family proved immovable, and at length he turned his attention to theological studies. He took rank among the most distinguished members of the church, and when not 30 years old became coadjutor to his uncle the archbishop Henri de Gondi. His winning manners, eloquence, and seeming Christian virtues secured for him unparalleled popularity among the Parisians. When the troubles of the Fronde broke out, he offered his services to the regent, Anne of Austria; but being coldly received, he used his popularity to cause the people of the metropolis to rise in arms against Mazarin, and became in effect the leader of the revolt. In 1651 he secured a cardinal's hat through his temporary alliance with the court, but he finally lost credit with all parties. Previous to the termination of the troubles, he was arrested by order of the queen, and was first taken to Vincennes, then to the castle of Nantes, whence he escaped. He took refuge in Spain, then in Italy, where his rank as a cardinal and his dignity of archbishop of Paris, in which he had nominally succeeded his uncle in 1654, secured him some respect. His return to France was permitted in 1661, but on condition of resigning his archbishopric, which he exchanged for

the abbacy of St. Denis, the richest preferment in France. He now gave up politics entirely, lived for the most part on an estate in Lorraine, and paid up his old debts, which amounted to more than 3,000,000 livres. His personal memoirs were printed for the first time in 1717 (3 vols. 12mo, Nancy), and have been often reprinted, with the addition of those of Guy-Joly and the duchess de Nemours, by which they are completed. They are included in Petitot's and Michaud and Poujoulat's *Collections de mémoires pour servir à l'histoire de France*. The most complete edition is that of Aimé-Champollion (4 vols. 12mo, 1859), with annotations and index.—See also *Œuvres du cardinal de Retz*, edited by Alphonse Feillet (vols. i. and ii., Paris, 1872).

RETZSCH, Friedrich August Moritz, a German designer, born in Dresden, Dec. 9, 1779, died near that city, June 11, 1857. He studied at Dresden, and in 1824 was appointed professor of painting there. His reputation rests upon his outline etchings illustrating "Faust" and the ballads of Goethe, Schiller, and Bürger, and Shakespeare's plays.

REUCHLIN (Hellenized into **CARNIO**), **Johann**, a German scholar, born in Pforzheim in 1455 (Feb. 22, according to Geiger), died in Stuttgart, June 30, 1522. On account of the sweetness of his voice he was admitted into the chapel of the margrave of Baden, and he was chosen by that prince to accompany his son Frederick in 1473 to the university of Paris. At the age of 20 he taught at Basel philosophy and Greek and Latin. He studied law in Orleans, and in 1481 was made teacher of jurisprudence and belles-lettres in the university of Tübingen. He received from the emperor Frederick III. the title of imperial councillor, and was employed in diplomacy. After the death of his patron Duke Eberhard of Würtemberg he went to the court of the elector palatine Philip at Heidelberg, where he made valuable additions to the library; and when the elector fell under the papal ban, Reuchlin went to Rome and obtained his absolution. For 11 years he was president of the Swabian confederate tribunal, but found time for the study of the eastern languages, and was constantly collecting Greek and Hebrew manuscripts. About 1509 a converted Jew named Pfefferkorn persuaded the inquisition of Cologne to solicit from the emperor Maximilian an order that all Hebrew books with the exception of the Bible should be burned. The emperor yielded, but subsequently asked the opinion of Reuchlin, who remonstrated strenuously, and the order was superseded. The inquisitors raised a furious cry against Reuchlin, charging him with being secretly inclined to Judaism. Reuchlin in 1511 published a defence under the title *Speculum Oculare*, in 1512 a German translation entitled *Augenspiegel*, and in 1513 his *Defensio contra Calumniatores*. In revenge the inquisitor Hoogstraaten formed a tribunal at Mentz, by the order of which the writings of

the German scholar were committed to the flames. An appeal was made to Pope Leo X., who referred the whole matter to the bishop of Spire, and that prelate declared Reuchlin innocent, and ordered the monks to pay the expenses of the investigation. Hoogstraaten appealed to the pope, who issued a mandate to suspend the proceedings against Reuchlin. The opening of the reformation prevented the matter from being revived; but the contest resulted really in favor of the advocates of classical literature, the study of Greek and Hebrew from that time becoming general among the Germans. (See EPISTOLÆ OBSCURORUM VIRO-
RUM.) In the war between Franz von Sickingen and Ulric, duke of Würtemberg, Reuchlin was obliged to leave Stuttgart, and in 1520 was made professor in the university of Ingolstadt by Duke William of Bavaria. He received an invitation to go to Wittenberg, and recommended in his place his cousin Philip Melancthon. Although suspected of a leaning toward Protestantism, he never renounced his connection with the Roman Catholic church. When in 1522 the plague broke out in Ingolstadt, he retired to Tübingen with the intention of devoting himself wholly to his studies, but soon sickened and died. Among his philological works are *Micropædia, sive Grammatica Græca* (Orleans, 1478); *Breviloquus, sive Dictionarium singulas Voces Latinas breviter Explicans*, which has been called the first Latin dictionary (Basel, 1478); *Rudimenta Hebraica* (Pforzheim, 1506); and *De Accentibus et Orthographia Hebræorum Libri III.* (Hagenau, 1518). His edition of the seven penitential psalms (Tübingen, 1512) is thought to have been the first Hebrew work printed in Germany. For the system of Greek pronunciation which he established, and which is known as iotacism or Reuchlinism, see GREECE (LANGUAGE AND LITERATURE), vol. viii., p. 209.—See *Johann Reuchlin, sein Leben und seine Werke*, by Ludw. Geiger (Leipsic, 1871).

RÉUNION, île de la, an island in the Indian ocean, belonging to France, between lat. 20° 50' and 21° 24' S., and lon. 52° 56' and 53° 34' E., 120 W. S. W. of Mauritius and about 410 m. E. of Madagascar; area, about 970 sq. m.; pop. in 1868, 212,536, about one sixth whites, and the rest chiefly negroes and coolies. The island is formed of two volcanic mountain ranges. The high central plateaus are known as *la plaine des Psalmistes* and *la plaine des Cafres*. The highest and northernmost peak, the Piton des Neiges, is more than 10,000 ft. high. In the south is the Piton de Fournaise, an active volcano, about 7,000 ft. high; the Gros Morne volcano is extinct. The climate is salubrious despite the great summer heats, violent hurricanes, and fevers. A girdle road finished in 1854 extends over 100 m. in the interior of the island. There are no navigable rivers, but many torrents and several lakes. The staple product is sugar, besides which the chief exports are mo-

lasses, coffee, cacao, and cloves. Horses, cattle, grain, rice, wines, beer, oils, salt fish, and other articles are imported. The chief commerce is with France. Since August, 1873, all foreign goods except tobacco are liable to only the same duties as those from France. The arrivals in 1873 comprised 185 French and 21 foreign vessels, and the total trade with France is estimated at about 36,000,000 francs.—The island was discovered in 1505 by the Portuguese Mascarenhas, whose name it bore till 1642, when the French took it and called it Bourbon. The English occupied it from 1810 to 1815, when it was restored to France. It was called Réunion during the revolution and the first empire, and Bourbon from the restoration till 1848, since which it has again been called Réunion. Slavery was abolished in 1848. The island is administered by a governor and a council of 30 members, the latter elected by the resident French. It is divided into the arrondissements du Vent and sous le Vent. The chief towns are St. Denis, the capital, St. Paul, and St. Benoît.

REUS, a city of Catalonia, Spain, in the province and 11 m. W. of the city of Tarragona; pop. about 25,000. It is situated on a gently sloping plain near the base of a low mountain range, and was formerly fortified. It consists of an old and a new town, the former dating from 1151, and the latter from the last century. There are 11 public squares and several subterranean aqueducts. The parish church of San Pedro is a stately Gothic pile with an imposing tower. Outside the town are two sanctuaries, one of which contains a gorgeous image of the Virgin, which is visited by large numbers of worshippers. The city has over 100 cotton and silk factories, and numerous oil mills, distilleries, and soap and earthenware factories. The commercial prosperity of Reus dates from the establishment there of English manufacturers in 1750.

REUSS, a river of Switzerland, tributary to the Aar, rising in the canton of Uri, near Mt. St. Gothard, within the small district where the Rhine, Rhône, and Ticino also have their source. It flows, fed by glaciers, in a northerly direction into the lake of Lucerne, and after leaving it follows a winding course, at first N. N. W. to the junction of the Emme, then N. E., and then crosses in a N. N. W. direction the canton of Aargau, joining the Aar at Windisch, east of Brugg. The total length of the river is about 100 m. Above Lake Lucerne it falls 4,500 ft., with many magnificent cascades; below it is navigable. The new road (built 1820-'32) over the St. Gothard crosses the Reuss eight times, one of the bridges being the celebrated Devil's bridge. (See DEVIL'S BRIDGE.)

REUSS, a territory of central Germany, between lat. 50° and 51° N., and lon. 11° and 13° E., enclosed by Saxe-Meiningen, Prussian Saxony, Saxe-Weimar, Altenburg, the kingdom of Saxony, and Bavaria; area, 443 sq. m.; pop.

in 1871, 134,126, nearly all Protestants. It consists of two unequal portions, separated by the southern part of Weimar. It is a part of what was formerly known as Voigtland, mostly hilly, and traversed by the upper courses of the White Elster and Saale. Cattle and sheep are reared, and linen, woollen, and cotton are manufactured. The territory forms now two sovereign principalities of the German empire, Reuss-Greiz and Reuss-Schleiz. The former division (area, 123 sq. m.) is the patrimony of the elder branch of the reigning family; its capital is Greiz, on the Elster. The latter (area, 320 sq. m.), which is ruled by the younger line, comprises the principalities of Schleiz, Lobenstein-Ebersdorf, and Gera, the capital being Schleiz. The house of Reuss had its origin in the 12th century. All the male members of the princely family have from the beginning been named Henry, at first distinguished by surnames and afterward by numbers, the elder line beginning a new series after reaching C. (100), and the younger with each century. The present reigning princes (1875) are Henry XXII. of the elder line, son of Henry XX., and Henry XIV. of the younger line, son of Henry LXVII.

REUTER, Fritz, a German novelist, born at Stavenhagen, Mecklenburg-Schwerin, Nov. 7, 1810, died in Eisenach, July 12, 1874. He studied at Jena, where he joined the *Burschenschaften*, and was in 1834 sentenced to death, but relieved after being imprisoned seven years. He afterward lived at Treptow and Eisenach, and acquired celebrity as a writer of works in Platt-Deutsch (complete ed., 13 vols., Wismar, 1863-'8). His posthumous works were published in 1875 (2 vols.).—See *Fritz Reuter und seine Gedichte*, by O. Glagau (Berlin, 1875).

REUTER, Paul Julius. See supplement.

REUTLINGEN, a town of Württemberg, capital of the Black Forest circle, on the Echatz, 20 m. S. of Stuttgart; pop. in 1871, 14,237. It has a pomological school, several other special schools, and a well endowed hospital. St. Mary's church, with a tower about 350 ft. high, which was erected in the 14th century and restored in 1844, is considered the most beautiful church of Württemberg. In 1863 a monument was erected here to Friedrich List, who was a native of the town. There are important manufactures of cloth, hats, powder, soap, &c. Reutlingen was in 1240 made a free imperial city, and in 1803 united with Württemberg. It has always been strongly Protestant, having subscribed the Augsburg confession in 1530.

REVEL, or **Reval**, a town of Russia, capital of the government of Esthonia, situated on the bay of Revel on the S. side of the gulf of Finland, 200 m. W. S. W. of St. Petersburg; pop. in 1867, 27,325. The town consists of two parts, the older and larger of which stands upon a rocky eminence, and the other is built along the beach. Buildings deserving notice are the provincial assembly house of the nobles, and

the imperial palace of Katharinenthal, founded by Peter the Great, with a beautiful park now open to the public. The town contains a gymnasium, a school of midwifery, several benevolent institutions and associations, Lutheran, Roman Catholic, and Greek churches, and public libraries. It is much resorted to as a watering place. A brisk export trade is carried on in corn, spirits, hemp, flax, timber, and other Baltic goods. Revel was founded by Walde-mar II. of Denmark about 1218, and was one of the most prosperous towns of the Hanseatic league. It subsequently fell under the sway of the knights sword-bearers of Livonia and under that of Sweden. Peter the Great obtained possession of it in 1710.

REVELATION, Book of the. See APOCALYPSE.

REVERE, Paul, an American patriot, born in Boston, Jan. 1, 1735, died there, May 10, 1818. He was of Huguenot descent, and was brought up to his father's trade of goldsmith. In 1756 he was a lieutenant of artillery in the colonial army, and was stationed at Fort Edward near Lake George. On his return he established himself as a goldsmith, and by his own unaided efforts learned the art of copperplate engraving, and at the breaking out of the revolutionary war was one of the four engravers then living in America. In 1766 he engraved a print emblematic of the repeal of the stamp act, which was very popular, as was likewise another called "The Seventeen Rescindors." In 1770 he published a print of "The Boston Massacre," and was one of the grand jury which refused to serve because of the action of parliament in making the judge independent of the people. In 1775 he engraved the plates, made the press, and printed the bills of the paper money ordered by the provincial congress of Massachusetts. By that body he was sent to Philadelphia to learn the art of making powder, and on his return set up a mill. He was one of those engaged in the destruction of the tea in Boston harbor (1773), and was sent to New York and Philadelphia to carry to those places the news of what had been done. When the decree for closing the port of Boston reached that city, he was again sent to those places to invoke their sympathy and coöperation. When Gen. Gage prepared an expedition to destroy the military stores of the colony at Concord, Warren, at 10 o'clock on the night of April 18, 1775, despatched William Dawes through Roxbury to Lexington, and Revere by way of Charlestown, to give notice of the event. Five minutes before Gen. Gage's order was received to prevent any American from leaving Boston, he was rowed across Charles river, and escaping the British officers rode in the still night to Lexington, rousing every house on his way. A little after midnight both messengers reached Lexington, roused Hancock and Adams, and then pushed on to Concord, but were afterward taken prisoners, brought to Lexington, and there released. Revere became a lieutenant colonel in the defence of the

state of Massachusetts, and after the war cast church bells and cannon. He built the copper-rolling works at Canton, Mass., now conducted by the Revere copper company.

REVOLVER. See **PISTOL**.

REYBAUD, Marie Roch Louis, a French author, born in Marseilles, Aug. 15, 1799. He was brought up as a merchant, made several commercial voyages, and in 1828 settled in Paris. He wrote for various liberal journals, and conducted the *Histoire scientifique et militaire de l'expédition française en Egypte* (10 vols. 8vo, with an atlas of 2 vols., 1830-'36), editing more particularly the six volumes relating to the expedition under Bonaparte, Kléber, and Menou. From 1837 to 1840 he published in the *Revue des Deux Mondes* a review of Utopian theories, under the title of *Études sur les réformateurs et socialistes modernes* (2 vols., 1840-'43; 7th ed., 1864), for which he received from the French academy the grand Montyon prize. His most popular work, *Jérôme Paturot à la recherche d'une position sociale* (3 vols. 8vo, 1843), was followed by *Jérôme Paturot à la recherche de la meilleure des républiques* (4 vols. 18mo, 1848). He has also written *La Syrie, l'Égypte et la Palestine* (4to, with plates, 1834 et seq.), in conjunction with Baron Taylor; *La Polynésie* (8vo, 1843); and *L'Industrie en Europe* (1856). M. Reybaud was elected to the legislature as a democrat in 1846, as a republican in 1848, and as a conservative in 1849; and he was a member of the consultative commission after the *coup d'état* of 1851.

REYER, Louis Étienne Ernest, a French composer, whose real name is Rey, born in Marseilles, Dec. 1, 1823. He was employed in the civil service at Algiers till 1848. His *Le Sélam*, for which Gautier wrote the words, was successfully performed in 1850, and in 1854 appeared his comic opera *Maitre Wolfgram*. His subsequent works comprise *Sacountala*, a ballet, and the opera of *La statue*. His *Érostrate* was less successful. His latest work is *Souvenirs d'Allemagne* (1875).

REYKIAVIK (Icel. *Reikjavig*), a seaport town and the capital of Iceland, at the head of a bay opening into Faxaflord, on the S. W. coast; lat. 64° 8' 24" N., lon. 21° 55' 15" W.; pop. about 1,400. It is the residence of the governor and the seat of the *althing* or legislature and of the supreme court. It has a cathedral church, a college with six professors, a school of theology and other schools, an observatory, a public library of 10,000 volumes, and two political newspapers. An important annual fair is held here. During summer regular steam communication is maintained with Leith and Copenhagen.—Reykjavik, founded in 874, was the first permanent settlement in Iceland. Its 1,000th anniversary was celebrated on Aug. 7, 1874; and on the same day the municipality of Copenhagen voted 6,000 rixdalers for the erection of a monument there in honor of Thorwaldsen, whose father was a native of Iceland.

REYNOLDS, a S. E. county of Missouri, drained by the head waters of the Big Black river; area, about 700 sq. m.; pop. in 1870, 3,756, of whom 11 were colored. It has an undulating surface and fertile soil. The chief productions in 1870 were 13,382 bushels of wheat, 168,255 of Indian corn, 17,680 of oats, 13,385 lbs. of tobacco, 6,607 of wool, and 48,000 of butter. There were 1,075 horses, 3,585 cattle, 4,810 sheep, and 9,953 swine. Capital, Centreville.

REYNOLDS, Sir Joshua, an English painter, born at Plympton, Devonshire, July 16, 1723, died in London, Feb. 23, 1792. He was educated in the free grammar school of Plympton, of which his father, the Rev. Samuel Reynolds, was master. In his 18th year he was placed with Hudson, the principal portrait painter of the time, and while with him made many careful copies of drawings by Guercino, which probably disqualified him in after life for drawing correctly from the living model. About the age of 20 he settled as a portrait painter in Plymouth, and through the assistance of Lord Mount Edgecombe, Captain (afterward Lord) Keppel, and other naval officers, commenced his career with considerable success. After the death of his father in 1746 he removed to London. In 1749 he accompanied Keppel in his ship, the *Centurion*, to the Mediterranean, and for three years and a half studied his profession in various cities of Italy. In the Vatican he caught a severe cold which resulted in permanent deafness. He was unable at first to appreciate the paintings of Raphael, and they never had much influence upon his style, which naturally imitated that of the great Venetian masters more than any others. He returned in the latter part of 1752 to London, and by a full-length portrait of Commodore Keppel, executed not long after his arrival, placed himself at the head of his profession in England, and in public estimation almost on a level with Vandyke. Thenceforth until the close of his life he enjoyed unvarying prosperity. He was soon obliged to employ several assistants to paint the draperies and other accessories of his pictures. His paintings were very numerous, 244 being sent to the academy for exhibition. Dr. Johnson mentions in 1762 that his professional income was 6,000 guineas a year, and it must subsequently have reached a much higher sum, as his price for heads was increased gradually from 10 guineas in 1752 to 50 in 1779, the other sizes being in proportion. Of his portraits, which, as Macaulay has observed, "have preserved to us the thoughtful foreheads of so many writers and statesmen, and the sweet smiles of so many noble matrons," the number is very considerable, and the technical merits, especially with respect to color and chiaroscuro, are of the first order. His portraits of women and children are among the most admired productions of modern art. Among the portraits of distinguished persons painted by him may be mentioned those of

Gen. Elliot (Lord Heathfield), Lord Ligonier on horseback, Sterne, Goldsmith, Dr. Johnson, Burke, Boswell, Wyndham, Earl Camden, Fox, Erskine, George III. and his queen, Horace Walpole, Beattie, John Hunter, Garrick between Tragedy and Comedy (for which in 1762 he received 300 guineas), Mrs. Siddons as the tragic muse (a picture which he valued at 1,000 guineas), the celebrated Georgiana, duchess of Devonshire, the earl and countess of Bute, and himself. His productions in history are generally admitted to be much inferior to his portraits, though many of them have been greatly admired. Among the most remarkable are his "Count Ugolino and his Sons," painted in 1773, and purchased by the duke of Dorset for 400 guineas; the designs of the cardinal and Christian virtues and the Nativity for the window of New college chapel, Oxford; the "Infant Hercules strangling the Serpents" (1784), now in St. Petersburg, for which the empress Catharine paid his executors 1,500 guineas; the "Cauldron Scene from Macbeth," "Puck," and the "Death of Cardinal Beaufort," for which he received respectively 1,000, 100, and 500 guineas; the "Holy Family," in the British national gallery; and "Cymon and Iphigenia," and the "Death of Dido," both in the queen's private collection. His "Strawberry Girl," formerly in the collection of Samuel Rogers, "Samuel Kneeling in Prayer," the portrait piece in the national gallery representing three ladies as the Graces decorating a terminal statue of Hymen, and the "Puck" above mentioned, illustrate very happily his taste and fancy in painting women and children. But many of these pictures are hastening to decay, owing to the introduction of wax and other incongruous mixtures, and the use of asphaltum glazes. Burnet says: "So anxious was he to combine the luminous qualities of the Venetian style with the rich transparency of Correggio and Rembrandt, that half his life was spent in trying experiments on the various modes of producing this union, and which has occasioned the decay and destruction of many of his works;" and Northcote tells us that he deliberately scraped away and destroyed Venetian paintings of value in order to discover their technical secrets. On the foundation of the royal academy in 1768, Reynolds was chosen its president and knighted. He retained this office until the close of his life, delivering within that period 15 annual discourses on art, which have been translated into various languages. A complete edition of his literary works forms vols. lxxviii. and lxx. of Bohn's "Standard Library," and contains his lectures, some contributions to the "Idler," remarks upon the works of Dutch and Flemish painters during a tour through the Netherlands in 1781, and other miscellaneous pieces, together with a life of the painter by Beechey. In private life Sir Joshua was remarkable for amiability and his varied and instructive conversation. Johnson, Gold-

smith, Burke, Garrick, and other distinguished literary men were his intimate associates, and he was one of the founders of the "Literary Club," of which they were prominent members. In the latter part of 1791 he was threatened with loss of sight in consequence of a tumor over his left eye, and at once resigned the practice of his art, the last effort of his pencil being a portrait of Fox. He died, after a painful illness, of a disease of the liver. He was never married, and his fortune, estimated at £80,000, was bequeathed to his niece, Miss Palmer, subsequently marchioness of Thomond.—There is a life of him by Northcote, valuable as a record of his conversation and aphorisms, and one by William Cotton. A biography left unfinished by C. R. Leslie was completed and published under the editorial supervision of Tom Taylor (2 vols., London, 1864-'5). See also "English Children as painted by Sir Joshua Reynolds," by F. G. Stephens (1866); "Sir Joshua Reynolds as a Portrait Painter," illustrated with autotype reproductions from engravings by Green, Watson, and others, by J. Churton Collins (fol., 1873); and "A Catalogue Raisonné of the Engraved Works of Sir Joshua Reynolds, from 1755 to 1820," by Edward Hamilton (1874).

RHABANUS. See **RABANUS**.

RHADAMANTHUS, in Greek mythology, one of the three infernal judges, the others being Minos and Æacus. Rhadamanthus judged the people of Asia and Africa, Æacus those of Europe, and the judgments of both were revised by Minos. Rhadamanthus was reputed the son of Jupiter, and sometimes of Vulcan, and was said to have been born at Cnossus in Crete, and to be the brother of Minos I., king of that island. At Thebes he married Alcmena, the widow of Amphitryon, and subsequently made a descent upon the Cyclades, which he conquered and over which he reigned.

RHÆTIA, a province of the Roman empire, which in the reign of Augustus was bounded N. by Vindelicia, E. by Noricum, S. by Gallia Cisalpina, and W. by the country of the Helvetii. Later Vindelicia was added to it, and the province extended as far N. as the Danube. At a still later period it was divided, the original province being called Rhætia Prima, and Vindelicia, Rhætia Secunda. Rhætia proper corresponded to the modern Grisons, Tyrol, and some of the northern parts of Lombardy. The valleys formed by the rivers Athesis (now Adige) and Enus (Inn) furnished fine lands for cultivation; but the inhabitants were engaged chiefly in the raising of flocks. They were a mountain race, fond of freedom, fighting, and plunder. They were subdued by the Romans under Drusus and Tiberius in 15 B. C., although they fought with desperate courage. Two roads were made through the province, the one leading from Augusta Vindelicorum (Augsburg) to Comum (Como), and the other from the same place to Verona. Their chief city was Tridentum (Trent), and the inhab-

itants were divided into tribes. Their descendants in Tyrol speak Romansh, which is a corruption of Latin intermixed with German, Celtic, and perhaps Etruscan elements. (See ETRURIA, and ROMANSH.) During the latter years of the empire the province became almost depopulated, but after the death of Theodoric it was settled by the Boioarii.

RHAMADAN. See RAMADAN.

RHAMNUS PURSHIANA. See supplement.

RHE. See Ré.

RHEA, in Greek mythology. See CYBELE.

RHEA, a S. E. county of Tennessee, bordered S. E. by the Tennessee river, drained by its branches, and intersected by a range of the Cumberland mountains; area, about 500 sq. m.; pop. in 1870, 5,538, of whom 531 were colored. The chief productions in 1870 were 32,639 bushels of wheat, 187,970 of Indian corn, 36,034 of oats, 1,332 tons of hay, 10,276 lbs. of tobacco, 9,088 of wool, and 9,041 gallons of sorghum molasses. There were 1,152 horses, 1,455 milch cows, 3,026 other cattle, 5,306 sheep, and 9,239 swine; and 3 wool-carding and cloth-dressing establishments. Capital, Washington.

RHEA SILVIA. See ROMULUS.

RHEGIUM. See REGGIO DI CALABRIA.

RHEIMS, or **Reims** (anc. *Durocortorum*, afterward *Remi*), a city of Champagne, France, in the department of Marne, on the Vesle, a tributary of the Aisne, near the Marne and Aisne canal, 82 m. E. N. E. of Paris; pop. in 1872, 71,994 (in 1851, 45,754). The cathedral, built in the early part of the 13th century, and completed in the 15th, is one of the finest Gothic edifices in Europe; in it the French kings were crowned for many centuries, the last coronation being that of Charles X., when the oil in the fragment of the holy ampulla was exhausted. (See AMPULLA.) Among the many other noteworthy buildings are the archbishop's palace and the hôtel de ville. There are several schools of high grade, a museum, and a library. A university existed here from 1547 to 1793. Rheims is a centre of the trade in Champagne wine, and of woollen, cotton, and other manufactures. The annual transactions in woollen goods are estimated at 75,000,000 francs.—Under the Romans Rheims was the capital of Belgica Secunda. Its bishops, dating from the 4th century, and its archbishops, from the 8th, were down to the revolution among the primates of France. After many sieges during the middle ages, it withstood one by the English under Edward III. (1359), but was occupied by them from 1421 to 1429, when they were expelled by Joan of Arc. The Germans occupied the city on Sept. 4, 1870.—See *Rheims, la ville des sacres*, by Baron Taylor (1854; new ed., 1860).

RHENISH CONFEDERATION (Ger. *Rheinbund*), a confederacy formed in 1806 by the kings of Bavaria and Würtemberg, the elector arch-chancellor of the empire, the elector of Baden, the duke of Berg, the landgrave of Hesse-

Darmstadt, the princes of Nassau-Usingen, Nassau-Weilburg, Hohenzollern-Hechingen, Hohenzollern-Sigmaringen, Salm-Salm, and Salm-Kyrburg, the duke of Arenberg, the princes of Isenburg-Birstein and of Liechtenstein, and the count von der Leyen. They communicated to the federal diet their withdrawal from the empire, Aug. 1, 1806, assigning as the reason for the separation the defects of the imperial constitution. At the same time Napoleon, the instigator of this movement, officially declared to the diet that he would no longer acknowledge a German empire. Francis II. consequently, on Aug. 6, abdicated as emperor of Germany, and took the title of emperor of Austria. Napoleon constituted himself "protector of the Rhenish confederation," the members of which bound themselves to take up arms against the enemies of France. The confederacy was subsequently joined by the elector of Würzburg, the king (formerly elector) of Saxony, the five Saxon dukes, the two princes of Schwarzburg, the three dukes of Anhalt, the new king of Westphalia, and many minor princes; so that by the end of 1808 the confederacy extended over 125,000 sq. m., with a population of nearly 15,000,000. The reverses of Napoleon in 1813 put an end to its existence, and its members were soon after merged in the Germanic confederation.

RHEUMATISM (Gr. *ῥεῦμα*, a flow, discharge). Acute rheumatism is an inflammation of the joints, characterized by general fever, by pain, heat, redness, and swelling of the joints affected, and by a tendency to leave one joint suddenly and fasten upon another. The affection sometimes commences by chills and fever, and general uneasiness; and these symptoms (rheumatic fever) may last for 24 hours or more before the local manifestations show themselves. More frequently the local symptoms make their appearance at the same time with the fever, and occasionally they are present some little time before it supervenes. The pain in the joint or joints affected, commonly but little felt while the patient is perfectly quiet, becomes intense on the slightest motion, so that he is rendered completely helpless. The superficial joints become swollen and tense, they are hotter than natural, and the skin covering them is generally more or less reddened. The swelling is sometimes mainly caused by effusion within the capsular ligament of the joint itself, at others by the inflammation and thickening of the fibrous tissues external to the joint. The pulse is generally full, strong, and moderately frequent, rarely rising over 100 beats in a minute; the skin is warm, and copious sour perspirations are commonly present; sweating was present in rather more than four fifths of the cases noted by M. Louis. The tongue is thickly coated, the bowels somewhat constipated, and the appetite completely

lost. The inflammation at first affects one or two joints, rarely three; after a variable time it commonly leaves the joints first affected as suddenly as it attacked them, and fastens on some other articulation; often however new joints are attacked without the disease leaving its original seat. As a rule, the larger joints are the ones most liable to be attacked, the knees, elbows, ankles, wrists, and hips; more rarely the smaller joints of the toes and fingers become affected. Besides the articulations, acute rheumatism frequently attacks the heart, not by metastasis, or transference of the inflammation from one part to the other, but by seizing on the fibrous textures of the heart as on one of the series of textures liable to the disease. Sometimes the pericardium is attacked (pericarditis), sometimes the lining membrane of the heart's cavities (endocarditis). (See HEART, DISEASES OF THE.) The younger the patient, the more liable is the heart to be affected; so that when rheumatism occurs previous to adult age, the heart is attacked in a large majority of cases. The rheumatic constitution is frequently hereditary, and rheumatism is peculiarly a complaint of cold, damp seasons and climates; but beyond this we know but little of the causes which induce it. The disease sometimes disappears in 10 or 12 days, sometimes lasts for months, while in other cases again it may lapse into a subacute or chronic state and continue indefinitely. Rheumatism, when uncomplicated, is rarely attended with immediate danger to life; but by damaging the heart it often lays the foundation for incurable disease. Occasionally fatal cases are met with.—Acute rheumatism has been treated in a great variety of ways. Bleeding, mercurials, mercurials with purgatives, opium, sulphate of quinine, and nitrate of potassa in large doses have been at various times resorted to. Of these methods, those by large doses of sulphate of quinine and by nitrate of potassa have seemed to have an influence in controlling and cutting short the disease, and the treatment by quinine appears to be successful in the acutest and most violent attacks; but they are both subject to inconvenience and dangers which counterbalance their advantages. The treatment which is most generally relied on is the alkaline. Tartrate of potash and soda (Rochelle salt) or acetate of potash is given in full doses short of producing purgation, until the urine is rendered alkaline. Occasionally a purgative may be required, or an opiate may be given at night to produce sleep. The treatment by lemon juice, advocated by Dr. Garrod, is in truth an alkaline treatment, the acid citrate of potash contained in the lemon juice being eliminated by the kidneys as a carbonate.—Chronic rheumatism presents itself under two forms. In one the joints are swollen and painful, the pain being aggravated by motion; there is no general fever, and the appetite may be good and the digestion sound. The affection is exceed-

ingly obstinate, attacking new joints without leaving those first affected; it frequently attacks the smaller joints, rendering them permanently swollen and deformed, while the immobility to which the joints are sometimes reduced may cause atrophy of the muscles connected with them. The treatment is unsatisfactory; sometimes alkalies or diuretics are of service, sometimes iodide of potassium seems of use; while the native sulphur waters, such as those of Sharon, St. Catharine's, the Virginia sulphur springs, &c., used both externally and internally, are frequently of great service. In the second variety of chronic rheumatism, sometimes termed passive rheumatism, the joints are neither red nor swollen, but simply stiff and painful, the pain being increased by motion, but not preventing labor or exercise. It is aggravated by cold and damp and relieved by heat. Warm salt water baths, and the use of flannel and stimulating liniments, afford some relief. Where it is possible, removal to a warm climate is advisable.

RHIN, Haut. See HAUT-RHIN.

RHINE (Ger. *Rhein*; Dutch, *Rijn* or *Ryn*; Fr. *Rhin*; anc. *Rhenus*), one of the principal rivers of Europe, having its sources in the Swiss canton of Grisons, and flowing into the North sea by an extensive delta of five mouths in Holland, after a circuitous but general N. N. W. course of about 800 m. The Rhine is usually divided into three parts, the upper, middle, and lower, the first lying within and along part of the boundary line of Switzerland, the second between Basel and Cologne, and the third between Cologne and the sea. The river originates in the Lepontine Alps in three branches, the Vorder, Mittel, and Hinter Rhein, the first and most western of which is considered the principal source. It rises in lat. 46° 38' N., lon. 8° 48' E., in the small lake of Toma, on the E. side of a mountain of the St. Gothard group, 7,687 ft. above the sea, runs as a torrent for about 12 m., during which it descends nearly 4,000 ft., and is joined at Dissentis by the Mittel Rhein from the right. It then flows in a general E. by N. direction for about 36 m. to Reichenau, where it receives the Hinter Rhein, also from the right, and becomes about 180 ft. wide, and navigable for river boats. Having continued the same course to Coire, it thence flows through a valley about 50 m. long and from 1 to 2 m. wide in a northerly direction to the lake of Constance, and for part of the distance forms the boundary line separating the principality of Liechtenstein and the Austrian district of Vorarlberg from Switzerland. After issuing from the lake at Constance it flows for a few miles in a westerly direction, till it enters the Untersee, which is about 30 ft. lower than the lake of Constance. It continues its course in the same direction to the falls of Schaffhausen, a little way below the town of that name, where the surface of the

river is 1,280 ft. above the sea, and the falls vary from 60 to 75 ft. in height. Below these falls the general course is still westerly, but very tortuous; and the river flows between mountains for about 50 m. to Laufenburg, where the navigation is again interrupted by a cataract. The bed is here narrowed to about 50 ft., and boats ascend and descend by means of ropes after being unloaded. About 10 m. below Laufenburg there is a rapid of considerable length, which is exceedingly dangerous, though it does not stop navigation. This is the last impediment to the navigation of the upper Rhine. Below this rapid the level of the river is 850 ft. above the sea, and it is only 50 ft. less at Basel. Above this point the Rhine receives numerous tributaries, the most important being the Aar, which, emptying about 12 m. above Laufenburg, brings the drainage of the greater part of Switzerland. From the lake of Constance to Basel the Rhine forms the boundary line between Baden and Switzerland.—Where the middle Rhine begins at Basel, the river has left the mountainous region, and changed its course to a northerly direction. It flows for about 200 m., to Mentz, through a valley from 30 to 50 m. wide, extending between the Black Forest and other mountains on the east, and the Vosges and the Hardt mountains on the west, forming the boundary line between Baden and Alsace, and Baden and Rhenish Bavaria, and passing through Hesse-Darmstadt. Between Basel and Strasburg, about 80 m., the fall of the river is $4\frac{1}{2}$ ft. per mile, and the current very rapid. The bed is wide and obstructed by numerous movable sand banks and small islands, which render the navigation intricate and dangerous. For the next 60 m., to Germersheim, the islands increase in size and are less liable to shift their position. Gold is washed from the sand and gravel along this part of its course, but not in paying quantities. Below Germersheim islands are rare, and the river flows sluggishly in large bends to Mentz, where its surface is only about 250 ft. above the sea. Many of the isthmuses formed by these bends have been cut through of late years, so as to shorten its course. Between Strasburg and Mentz it is navigable for boats of about 100 tons burden, which descend with the current, but in going up are tracked chiefly by horses. Between Mentz and Cologne, about 120 m., the course of the river is first W., then N. N. W., and afterward mostly N. W. It first forms the boundary between Hesse-Darmstadt and the Prussian province of Hesse-Nassau, and then between the latter and the Prussian Rhine province, which it enters near Coblenz. This part of the river runs between two mountain regions, where in many places the hills come so close to the banks of the river that there is scarcely room for a road. The produce of the extensive vineyards in this neighborhood is known as Rhenish wines. There is a ledge of rocks at Bingen which pre-

vents steamers and barges from passing during foggy weather or at night. The surface of the water at Cologne is 120 ft. above the sea. During its middle course the Rhine receives many tributaries; but, with the exception of the Moselle, those from the west are all short and not navigable. On the right or E. side the tributaries are much larger and more numerous, the most important being the Neckar, Main, Lahn, and Sieg.—The lower Rhine extends for about 300 m. from Cologne to its mouths, and flows through a low level country, with the hills of Sauerland near its E. bank between Cologne and Düsseldorf. From Cologne to Wesel its course is mostly N. N. W., though very tortuous. From Wesel to the frontiers of Holland it flows N. W. Below Cologne the Rhine is navigable for sea-going vessels, and the fall from thence to its mouth is only about 4 in. in a mile, and the current extremely sluggish. Shortly after entering Holland, near the village of Pansterdam, the Rhine divides into two arms, the southern of which takes the name of Waal, the northern preserving that of Rhine. The Waal, which joins the Maas, is here 210 yards broad, while the Rhine is only 114 yards, and about two thirds of the volume of water runs into the former. After the separation the Rhine flows N. N. W., and near Arnhem, 12 m. lower down, it again divides into the Yssel, which runs N. to the Zuyder Zee, and the Rhine, which flows W. At Wyck, about 30 m. lower down, the Rhine divides for the third time, into the Leck and Kromme Ryn (Crooked Rhine), the former of which is the larger. The Kromme Ryn runs N. W. to Utrecht, where the last division takes place, into the Vecht, which flows to the Zuyder Zee, and the Oude Ryn (Old Rhine), which continues westward past Leyden. The mouth of the Oude Ryn was formerly obstructed by dunes or sand hills, and the river did not reach the sea; but in 1807 a canal was cut through them, and it now communicates with the North sea at Katwyk, a few miles N. W. of Leyden. Before it begins to form the delta the lower Rhine is augmented by the Erft, Ruhr, and Lippe, all of which are navigable. The Yssel was originally a canal cut by Drusus to unite the Rhine with the river now called Oude Yssel (Old Yssel). The Leck, or middle branch of the Rhine, was also originally a canal made by the Roman general Corbulo; but in A. D. 839 its bed was so much enlarged by a flood that it became the main stream. The delta of the Rhine is bounded N. by the Zuyder Zee, E. by the Yssel, S. by the Waal and Maas, and W. by the North sea; it comprehends the three Dutch provinces of North and South Holland and Utrecht, and about two thirds of Gelderland, all of which country would be subject to inundations were it not protected by embankments. These embankments begin in the Prussian district of Düsseldorf, extend along the banks of the different arms of the Rhine

to the sea, and are generally from 25 to 30 ft. above the lowest level of the river.—The basin of the Rhine is estimated at 80,000 sq. m., of which 13,000 belong to the upper, 40,000 to the middle, and 27,000 to the lower Rhine. The river is generally covered with ice for from six weeks to two months in winter; and when snow accumulates and a thaw suddenly sets in, the lowlands are liable to inundations that are sometimes attended with great loss of life and property. The different arms of the Rhine are united by numerous canals, and the river itself is connected by canals with the Saône and Rhône, the Scheldt, Maas, and Danube; and an extensive trade is carried on upon all these as well as the chief navigable tributaries, the Moselle, Main, Ruhr, and Neckar. The annual traffic is of great importance, and is regulated by treaties between the different states through which it runs, all of which lay toll duties on vessels and goods passing their boundaries.—The Rhine is celebrated for the picturesque beauty of the scenery in the upper and middle part of its course, and is annually visited by a multitude of tourists. More than 1,000,000 passengers are conveyed up and down annually. Steam vessels ply between the principal towns on its banks. It is crossed at several points by pontoon bridges, and many of the principal places on either side are connected by railways. There is great discrepancy among ancient writers with regard to the number of mouths by which the waters of the Rhine formerly flowed into the sea. Some speak only of two; others say there were three; and Cæsar says there were several branches.

RHINE, Province of the, or Rhenish Prussia (Ger. *Rheinprovinz*, *Rheinpreussen*, or *Rheinland*), a W. province of the kingdom of Prussia, lying on both sides of the Rhine, bordering on the provinces of Westphalia and Hesse-Nassau, the grand duchy of Hesse, Bavaria, Alsace-Lorraine, Luxemburg, Belgium, and Holland; area, 10,416 sq. m.; pop. in 1871, 3,579,347, of whom about 74 per cent. were Roman Catholics, 25 per cent. Protestants, and the remainder Jews. The N. part of the province is level, the E. and S. parts mountainous. The principal mountain ranges are the Hohe Venne, the Eifel (about 2,500 ft. high), and the Hunsrück, W. of the Rhine, and the Siebengebirge, E. of it. The chief river next to the Rhine is its western affluent the Moselle. The province is rich in minerals, and is fertile and well cultivated. The manufactures are extensive, and comprise almost every species of industry. It is divided into the administrative districts of Cologne, Düsseldorf, Coblenz, Treves, and Aix-la-Chapelle, and contains besides the cities of those names Bonn, Crefeld, Elberfeld, Jülich, Wesel, Berg, and Cleves. Capital, Coblenz.

RHINOCEROS (Gr. *ῥίς*, nose, and *κέρας*, horn), an ungulate mammal, surpassed in size among present terrestrial animals only by the elephant, and perhaps by the hippopotamus. The head

is long and triangular, and from the upper surface of the end of the nose springs a single or double horn, composed of a solid mass of agglutinated hairs or horny fibres; this is supported on the nasal bones, though not connected with them, belonging entirely to the skin and removed with it; it is often more than 3 ft. long, and gently curved backward, and so sharp as to make it a very formidable weapon; when there are two horns, the hinder is generally much the shorter. There are no canine teeth, and the incisors sometimes fall out when the animal is full-grown; the molars are $\frac{7}{2}$, with lunate ridges; the nose is blunt and rounded, and the upper lip elongated and very movable; the eyes are small, and the ears moderate, tipped with rigid hairs; the body is very bulky, the legs short and strong, and the feet three-toed with as many broad hoofs; the tail is short, round at the base, compressed laterally toward the end, and hairy at the tip; on the hind feet are sebaceous glands opening on the posterior surface, in a sacculated inversion of the skin, as on the anterior surface of the feet of sheep; the mammae are two, and inguinal. The skin is naked, very rough and hard, divided into large folds which give to the animal a shielded appearance; it is impervious to the claws of the lion and tiger, will turn the edge of a sword, and is impenetrable to ordinary musket bullets. The stomach is large and simple, the intestinal canal eight times as long as the body, the villi of the small intestine greatly developed, the large intestine very wide, and the cæcum sacculated. The ribs are 19 pairs, the iliac bones very wide, and the femur with a prominent ridge on the outer border terminating in a hook-like process and with the great trochanter exceedingly prolonged; the incisor teeth seem to be developed in an inverse ratio to the horns; the brain is large, but the relative size of the cerebrum, especially the upper and anterior portion, is less than in the elephant. The rhinoceros is found in the warm regions of Asia and Africa, living with the elephant in forests, and feeding on herbage and leafy twigs and shrubs. It is peaceable unless irritated; it then charges upon its enemy with the head down and the horn forward; though not very active, its great weight and strength make it a formidable assailant, and a match even for the elephant. The senses of smell and hearing are so acute that the hunter must approach against the wind and in perfect silence; it is hunted for sport by Europeans, and the natives eat the flesh, and sell the skin to traders for the manufacture of canes, whips, and defensive armor, and the horns for boxes and cups. In its native forests the rhinoceros has a tortoise-like appearance, with its stolid expression, slow movements, thick armor, short legs and tail, and curved upper lip.—Several species have been described, of which the best known is the single-horned or Indian rhinoceros (*R. unicornis*, Linn.; *R. Indicus*, Cuv.). This animal measures about 12 ft. in length,

with a circumference of the same, and a height of 6 ft.; the skin is very thick, arranged in broad folds in many parts, rough and tuberculated, and deep purplish gray. It was well known to the ancients, and is generally believed to be the unicorn or *reem* of the sacred writings, though not of the Arabian poets, which was either a wild bull or an antelope. It leads a quiet indolent life, wallowing on the marshy borders of rivers and lakes, and bathing in their waters; it moves slowly, the head carried low as in the hog; its strength enables it to pass with ease through the thickest jungles; it is found in the warmer parts of continental India. In captivity, especially if taken young, it is gentle, obedient, and grateful for kind treatment, with occasional paroxysms of rage without apparent cause; it is fond of bread, fruit, and particularly sweets, collecting and holding its food by the long upper lip; it is not uncommon in menageries, and has been trained to perform simple tricks, but its intelligence is far inferior to that of the elephant; though these two animals are said to have a natural antipathy to each other, they agree very well together in confinement. The Java rhinoceros (*R. Sondaicus*, Horsf.), with a single horn, is confined to Java; the epidermis is arranged in pentagonal shields. The Sumatran rhinoceros (*R. Sumatrensis*, Cuv.) is a smaller species with two horns and a comparatively smooth skin. For an account of its breeding see Maunder's "Treasury of Natural History" (London, 1874).—The black African rhinoceros (*R. bicornis*, Linn.; *R. Africanus*, Camper), the *borélé* of the S. African aborigines, has two horns, and a smoother skin, wrinkled instead of folded;

Black African Rhinoceros (*Rhinoceros bicornis*).

the incisors are either latent or fall away early; the horns, which as in the other species occur in both sexes, are brightly polished by rubbing against the trees, and the posterior is only one third the length of the anterior, the latter being rarely more than 18 in. The general color

in the male is black, in the female pale yellowish brown with purplish tints on the head, and the groins flesh-colored; the head seems too deep in proportion to its length, giving it a very clumsy appearance; the upper lip is scarcely at all prolonged; the neck short and thick, with a deep furrow where it joins the head, and a rudimentary hump on the shoulder. In size and habits it resembles the Indian species; it was formerly found even on the slopes of Table mountain, but has now been driven far beyond the limits of Cape Colony into the interior, where it is seldom molested. They keep concealed by day, wandering at night in search of water and food, especially the branches of the wait-a-bit thorns; the gait is equal to that of a good horse, and when disturbed the head is carried high; they are usually seen singly or in pairs. They are suspicious and savage, attacking the traveller, and so lean that the flesh is rarely eaten; wherever the footprints are seen, the ground and bushes are found torn up; this they do, not from rage, but in a mere wanton display of strength; they also dig the ground with the fore feet, throwing it backward in the manner of a dog. Dr. A. Smith, in his "Zoology of South Africa," makes three species; Dr. Livingstone considers that all the species made by naturalists beyond two are based on mere differences in size, age, and direction of horns, which vary much within the limit of a single species. The *R. keitloa* (A. Smith) is a rather smaller species, with two horns nearly equal in length, with more slender head and longer neck than in the *borélé*; the general color is pale brownish yellow, with a black mark on the inside of the thighs; the upper lip is elongated; it is swift, fierce, and dangerous, comparatively rare, and not found further south than lat. 25°.—The white rhinoceros (*R. simus*, Burch.), the *mohooohoo* of the Bechuanas, is the largest of the genus; the color is pale brownish white, with purplish tints on the shoulders and posterior parts; the head is comparatively long and slender, the face concave, forehead convex, neck long with three well marked wrinkles on nape, the nose truncated, the upper lip perfectly square and ox-like, and the shoulders with a distinct hump; the horns are two, the first very long and pointed, the second just behind it, short and obtuse. This is a rare species, timid, unsuspecting, easily captured on account of its slow movements, and much prized by the natives for its fat flesh; the food is principally grass. The Bechuanas call the rhinoceros by the general name of *chukuroo*. The best friend of this animal is a bird of the genus *buphaga*, known as the rhinoceros bird, which warns it of the approach of danger. It makes a harsh cry in the ear of the sleeping rhinoceros, which awaking rushes off into the forest to escape the hunter; it perches on the animal's back, returning when frightened or swept off by the branches, and remains with it all night. Cumming says he has often shot the rhinoceros

at midnight at fountains, and that these birds, imagining "chukuroo" was asleep, would remain until morning, and on his approaching, before taking flight, would try to awaken him from his deep sleep.—The rhinoceros played an important part among the animals of the tertiary and diluvial epochs, numerous species of great size occupying cold countries of Europe, where they now could not exist. Since 1781 many fragments have been found in Germany, Italy, France, England, and Russia. A few species have been detected in the lower miocene of France, of which the *R. tapirinus* (Pomel), of the size of a tapir, belonged to Kaup's group of *acerotherium*, characterized by two large incisors in each jaw, four toes on the anterior feet, and probably a very small, if any, nasal horn. In the upper miocene of France and Germany occur many species which De Blainville has united into the single *R. incisivus*, without bony partition between the nostrils, with two large incisors in each jaw and three toes on each foot. In the pliocene of France and England are species without bony nasal partition and with moderate incisors, like the *R. megarhinus* (Cuv.). The best known fossil species is the *R. tichorhinus* (Cuv.), of the diluvial deposits of Siberia and the most of Europe, contemporary with the mammoth. The most remarkable specimen was found in 1731 in arctic Siberia by a hunter; the body was well preserved and half buried in the frozen sand, in lat. 64° N.; it was $11\frac{1}{2}$ ft. long, with a skin like leather covered with short hair; the nasal bones were curved in front of the nose to unite with the intermaxillaries, and the partition between the nostrils was bony to the extremity, giving greater solidity to the nose for the support of the two large horns, which were further separated than in the living species; the incisors fell out in the adults, and the symphysis of the lower jaw was very long; coming nearest to the *R. bicornis* of Africa, it had a longer and narrower cranium, more bulky body, and shorter and stouter limbs. It occurs in diluvial sands, in caverns, and in bone breccia. This genus has also been found in the tertiary and diluvial deposits of Asia; Cautley and Falconer describe four species among the Sivalik hills of northern Hindostan. The most singular fact in connection with the geological distribution of the rhinoceros is its occurrence during the diluvial period in America, like the elephant not now existing on this continent; several species differing from *R. tichorhinus* are described by Profs. Leidy, Marsh, and others, from the tertiary of Nebraska, Texas, the upper Missouri, California, and the neighboring territories. The genus *elasmotherium* of Fischer probably comes near if not in the rhinoceros family; judging from the teeth, and the size, form, and thickness of jaw, it must have been an animal of heavy proportions, with the size and habits of the rhinoceros, and essentially herbivorous; it was found in Siberia. The family *brontotherida*, so fully

described by Profs. Marsh and Cope, from the miocene of Colorado and the adjoining territories, seems to have combined some of the characters of the rhinoceros and elephant, which succeeded them in the pliocene period.

RHIZOPODS. See FORAMINIFERA, GLOBIGERINA, and PROTOZOA.

RHODE ISLAND, one of the thirteen original states of the American Union and one of the New England states, the smallest of the 37 of which the Union is now composed. It is bounded N. and E. by Massachusetts, S. by the Atlantic ocean, and W. by Connecticut, and lies between lat. $41^{\circ} 9'$ and $42^{\circ} 8' N.$, and lon. $71^{\circ} 8'$ and $71^{\circ} 53' W.$; extreme length N. and S. $47\frac{1}{2}$ m., greatest breadth E. and W. 40 m.; area, 1,306 sq. m. It is divided into five counties: Bristol, Kent, Newport, Providence, and Washington. These are subdivided into two cities, Providence (pop. in 1875, 100,675) and

State Seal of Rhode Island.

Newport (pop. 14,028), and 34 towns. Providence and Pawtucket, which had 68,904 and 6,619 inhabitants respectively in 1870, have since received territory from North Providence. The largest towns are Pawtucket (pop. in 1875, 18,464), Woonsocket (13,576), Warwick (11,614), Lincoln (11,565), Bristol (5,829), Cranston (5,688), Westerly (5,408), Burrillville (5,249), Johnston (4,999), Coventry (4,580), and South Kingstown (4,240). The population of Rhode Island in 1730 was 17,935; in 1755, 40,414; in 1770, 59,678. According to the federal enumerations, it has been as follows:

CENSUSES.	White.	Free colored.	Slave.	Aggregate.
1790.....	64,470	3,407	945	68,825
1800.....	65,438	3,304	380	69,122
1810.....	73,214	3,609	108	76,931
1820.....	79,413	3,554	43	83,050*
1830.....	93,621	3,561	17	97,199
1840.....	105,587	3,288	5	108,830
1850.....	143,875	3,670	..	147,545
1860.....	170,649	3,952	..	174,620
1870.....	212,219	4,980	..	217,353

* Including 44 persons not classified.

RHODE ISLAND

THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS

The aggregate included 19 Indians in 1860, and 154 in 1870. The gain in population from 1860 to 1870 was 24.47 per cent. Rhode Island at the latter date had 166,43 inhabitants to a square mile, being next to Massachusetts the most densely populated state in the Union. The total population in 1875, according to the state census, was 258,239. Of the population in 1870, 161,957 were natives and 55,396 foreigners, 104,756 males and 112,597 females. Of the natives, 125,269 were born in the state, 18,719 in Massachusetts, 5,524 in Connecticut, 3,932 in New York, 1,875 in Maine, and 1,242 in New Hampshire. There were 45,371 persons born in the state living in other parts of the Union. Of the foreigners, 42,984 were natives of the United Kingdom (31,534 Irish, 9,291 English, and 1,948 Scotch), 10,242 of British America, and 1,201 of Germany. There were in the state 27,834 males and 27,941 females between 5 and 18 years of age, 44,377 males between 18 and 45, and 58,752 males 21 years old and upward, of whom 43,996 were citizens of the United States and 14,756 unnaturalized foreigners. There were 46,133 families, with an average of 4.71 persons to each, and 34,828 dwellings, with an average of 6.24 to each; 15,416 persons 10 years old and upward who could not read, and 21,921 who could not write, of whom 4,444 were native and 17,477 foreign born, 2,531 between 10 and 15 years of age, 2,588 between 15 and 21, and 16,802 21 and upward, of whom 6,218 were males and 10,584 females. The number of blind persons was 121; of deaf and dumb, 64; of insane, 312; of idiotic, 123. The number of paupers supported during the year ending June 1, 1870, was 1,046, at a cost of \$97,702; receiving support on that date, 634, of whom 192 were foreigners; persons convicted of crimes during the year, 209; in prison on June 1, 180, of whom 55 were foreigners. Of the 88,574 (66,859 males and 21,715 females) persons 10 years old and over returned as engaged in all occupations, 11,780 were employed in agriculture, 19,679 in professional and personal services, 10,108 in trade and transportation, and 47,007 in manufactures, including 20,504 cotton and woollen mill operatives. The number of deaths, according to the census of 1870, was 2,741, of which 552 were from consumption and 169 from pneumonia. Rhode Island was formerly the abode of the Narragansett Indians, a large and powerful tribe, of which there is a small remnant. In 1709 the sachem Ninegret gave a quitclaim to the colony of all the Indian lands, except a reservation in the town of Charlestown, portions of which have from time to time been sold. Of this reservation there remains 2,685 acres, 637 of which are arable, and the remainder swamp and timber lands. The tribe now consists of fewer than 150 persons, all of whom are of mixed blood. They possess a church and a school house, and about a third of the tribe can read and write.—The surface of the state is gen-

erally rough and hilly, but has no elevations which can with propriety be called mountains. Mt. Hope, the seat of the famous Indian king Philip, near Bristol, is a considerable elevation, but the hills near Woonsocket in the north, and Hopkins hill near the centre of the state, have a greater height above the sea. Narragansett bay, which divides the state into two unequal parts, leaving far the greater portion on the west, extends N. from the Atlantic ocean a distance of 28 m. It is from 3 to 12 m. wide, and holds in its embrace the islands of Aquidneck, or Rhode island, Canonicut, Prudence, and several smaller ones. The first named, which has been called the "Eden of America," is 15 m. long, from 3 to 3½ m. wide, and contains about 50 sq. m. It comprises the city of Newport, the town of Middletown, and the greater part of Portsmouth. Newport, near its S. end, is a celebrated watering place. Newport harbor, which lies between Canonicut and Rhode island, is one of the finest in the world, and has a depth of water sufficient for the largest ships. Canonicut is 7 m. long and about 1 m. wide, and forms the town of Jamestown. Prudence island lies N. E. of Canonicut, and is of less extent; it forms a portion of the town of Portsmouth. Projecting southward from the mainland on the east is a peninsula which divides Narragansett bay and forms Mt. Hope bay, at the head of which Taunton river enters. In the Atlantic, about 10 m. S. by W. of Point Judith (at the W. entrance of Narragansett bay), is Block island, so named from the Dutch captain Adriaen Block, who visited it in 1614; it is 8 m. long by from 2 to 5 m. wide, contains a large salt pond, and forms the town of New Shoreham, Newport co. The islanders support themselves chiefly by fishing. Sheep in considerable numbers are raised, and excellent butter and cheese are made there.—The rivers in the state are small, but have considerable falls, and their waters are used over and over again during their whole course for manufacturing purposes. The Pawtucket or Blackstone river rises in Massachusetts, runs S., and flows into Providence river. At Pawtucket it has a fall of from 30 to 40 ft., below which it bears the name of Seekonk river. The Woonasquatucket and Mooshassuck flow into a cove within the city of Providence which is connected with Providence river. Pawtucket river enters Narragansett bay 5 m. below Providence. It courses through the central parts of the state and abounds with falls; hence it is used to its full extent for mills and various kinds of manufacturing establishments. Pawcatuck river waters the S. W. section of the state, and falls into Stonington harbor; along its course are many thriving manufacturing villages. Providence river is the northern arm of Narragansett bay, and is navigable to Providence for ships of 1,500 tons burden.—The western portions of the state are very uniform and simple in their geological character,

the primary stratified and unstratified rocks generally prevailing with great uniformity. Cumberland in the north, on the contrary, is a very complicated geological district. As a general thing it may be said that the geological formation which distinguishes S. E. Massachusetts extends to the N. parts of Rhode Island. The S. section is chiefly of a later era. Anthracite coal of an inferior quality exists in Cumberland and on Rhode island, in both of which localities it has been mined to a considerable extent. Iron ore is found in several places. Limestone abounds in the N. section, and there are some excellent quarries of marble, freestone, and granite. Serpentine is also abundant.—The climate of the whole state is mild, owing to its proximity to the sea. Newport and its vicinity, more affected by the vapors from the Atlantic, is milder than the N. parts of the state. The soil is moderately fertile, but rough in many parts and difficult of cultivation. The island of Rhode Island was formerly well wooded, but it was entirely denuded of its forest trees while in possession of the British in the revolutionary war. It is now noted for its fine cattle, sheep, butter, and cheese. The soil of the islands is slaty, yet they are the most productive portions of the state. There is very little alluvial land. Pine plains are found in several places. Oak, walnut, and chestnut are the prevailing growth, with some pine. In the S. parts are some large cedar swamps. Indian corn, rye, and oats are the principal cereals. Wheat is rarely sown. On the whole the lands are better adapted to grazing than to the cultivation of cereals. The number of acres of improved

land in farms in 1870 was 289,030; of farms, 5,368, of which 440 contained less than 10 acres each, 719 between 10 and 20, 1,960 between 20 and 50, 1,488 between 50 and 100, 750 between 100 and 500, and 11 more than 500; cash value of farms, \$21,574,968; of farming implements and machinery, \$786,246; wages paid during the year, including value of board, \$1,124,118; estimated value of all farm productions, including betterments and additions to stock, \$4,761,163; value of orchard products, \$43,036; of produce of market gardens, \$316,133; of forest products, \$254,683; of home manufactures, \$37,847; of animals slaughtered or sold for slaughter, \$755,552; of live stock, \$3,135,132. The productions were 784 bushels of wheat, 20,214 of rye, 311,957 of Indian corn, 157,010 of oats, 33,559 of barley, 1,444 of buckwheat, 9,920 of peas and beans, 669,408 of Irish potatoes, 142 of sweet potatoes, 954 of clover seed, 1,938 of grass seed, 796 lbs. of tobacco, 77,328 of wool, 941,199 of butter, 81,976 of cheese, 249 of hops, 498 of wax, 6,290 of honey, 20 gallons of sorghum molasses, 765 of wine, 1,944,044 of milk sold, and 89,045 tons of hay. The live stock on farms included 7,770 horses, 43 mules and asses, 18,806 milch cows, 5,821 working oxen, 9,748 other cattle, 23,938 sheep, and 14,607 swine; besides which there were 3,343 horses and 5,730 cattle not on farms.—Manufacturing is the most important interest of the state. The chief water power is in Providence and Kent counties. The city of Providence is largely engaged in manufacturing by steam power. The following table is compiled from the last three federal censuses:

YEAR.	Number of establishments.	Number of hands employed.	Amount of capital invested.	Annual wages.	Value of materials used during year.	Value of annual product.
1850.....	864	20,967	\$12,985,676	\$5,047,030	\$13,186,703	\$22,117,683
1860.....	1,191	32,490	24,278,295	8,760,125	19,858,515	40,711,296
1870.....	1,550	49,417	66,557,322	19,354,256	73,154,109	111,418,354

Of the hands employed in 1870, 28,804 were males above 16, 14,752 females above 15, and 5,861 youth. The motive power was furnished by 402 steam engines of 23,546 horse power, and 456 water wheels of 18,481 horse power. In that year, though 32d among the states in population, Rhode Island was 10th in the value

of manufactures. In proportion to population it ranked first, averaging \$512 61 of manufactured products to each inhabitant. The following table gives the statistics for 1870 of the leading branches, together with the rank of Rhode Island and the states that surpass it in value of products in each branch:

INDUSTRIES.	Establishments.	Hands.	Capital.	Value of materials.	Value of products.	Rank.	States superior in value of products.
Cotton goods.....	140	16,872	\$18,848,300	\$13,286,315	\$22,072,208	2	Mass.
Woollen goods.....	65	6,363	8,167,500	8,089,948	12,558,117	5	Mass., Pa., Conn., N. Y.
Worsted goods.....	11	1,631	2,900,000	1,736,210	2,835,950	3	Mass., Pa.
All textiles*.....	219	25,054	30,352,800	23,280,096	37,907,670	3	Mass., Pa.
Printing cotton and woollen goods.....	9	2,996	6,770,000	14,604,962	17,842,450	1
Bleaching and dyeing.....	15	780	1,474,000	13,842,026	15,138,723	2	Mass.
Cotton and woollen machinery.....	70	3,087	9,583,060	1,412,715	4,816,376	2	Mass.
Jewelry.....	71	1,579	1,850,400	1,858,581	3,043,846	3	N. Y., N. J.
Plated ware.....	9	380	634,700	564,900	1,212,240	2	Conn.
Screws.....	2	972	7,080,000	718,465	1,882,318	1
India-rubber and elastic goods.....	2	845	403,000	901,053	1,804,568	5	Conn., Mass., N. Y., N. J.

* Including cotton, woollen, worsted, and linen goods.

—Rhode Island is divided into three customs districts, Bristol and Warren, Newport, and Providence. The direct foreign commerce is not extensive, but there is a large coasting trade. The statistics of the foreign commerce

for the year ending June 30, 1875, including imports and exports and entrances and clearances, with the number and tonnage of vessels belonging in the different districts on that date, are contained in the following table:

DISTRICTS.	Imports.	Exports.	ENTRANCES.		CLEARANCES.		BELONGING.	
			No.	Tons.	No.	Tons.	No.	Tons.
Bristol and Warren.....		\$5,100	1	191	20	1,265
Newport.....	\$1,750	11,632	6	617	5	620	137	6,643
Providence.....	312,950	23,088	143	22,590	125	19,636	182	36,485
State.....	\$314,700	\$39,820	154	23,207	131	20,447	289	44,593

Of the vessels belonging in the state, 48, with an aggregate tonnage of 21,570, were steamers. Cod and mackerel fishing for the New York and other markets is carried on to a considerable extent, chiefly from Newport. The number of vessels engaged in this business on June 30, 1875, was 105, with an aggregate tonnage of 1,547. Menhaden, scup, and bluefish are also extensively caught, while clams and other shellfish are abundant on the shores of Narragansett bay. The latest published statistics of the coasting trade, for the year ending June 30, 1875, are as follows:

DISTRICTS.	ENTRANCES.		CLEARANCES.	
	No.	Tons.	No.	Tons.
Bristol and Warren.....	39	5,471	61	50,561
Newport.....	330	801,948	327	806,039
Providence.....	844	748,765	157	113,923
State.....	1,213	1,556,184	545	969,623

Rhode Island is well supplied with railroads. The particulars of the different lines at the beginning of 1875 are shown in the following table:

LINES.	TERMINI.	Length in state.	Total length when different from preceding.
Boston and Providence.....	Boston, Mass., to Providence.....	101½ m.	44 m.
Boston, Hartford, and Erie (Woonsocket division)	Brookline, Mass., to Woonsocket.....	1 "	32½ "
Fall River, Warren, and Providence.....	Warren to Fall River, Mass.....	9 "	5½ "
Hartford, Providence, and Fishkill.....	Providence to Waterbury, Conn.....	26½ "	122½ "
Newport and Wickford.....	Wickford Junction to Wickford, opposite Newport	45 "	62½ "
New York, Providence, and Boston.....	Groton, opp. New London, Conn., to Providence.	2 "	67½ "
Old Colony.....	Boston, Mass., to Newport.....	14½ "
Pawtuxet Valley.....	River Point to Hope.....	2½ "
Providence and Springfield.....	Providence to Pascoag.....	23 "
Providence and Worcester.....	Providence to Worcester, Mass.....	18 "	44½ "
Providence, Warren, and Bristol.....	Providence to Bristol.....	13½ "
Warwick.....	Auburn to Coweset Bay.....	8½ "
Wood River branch.....	Wood River Junction to Locustville.....	5½ "
Total.....		176 m.

There are 62 national banks, which on Oct. 2, 1874, had an aggregate capital of \$20,504,800; outstanding circulation, \$12,990,605; individual deposits, \$7,930,653 64; total assets, \$49,008,801 37. The number of state banks is 15 (12 in Providence and 3 in Newport), which on Dec. 2, 1874, had an aggregate paid-in capital of \$3,210,000, and deposits to the amount of \$1,537,701 22; total assets, \$5,229,253 46. The institutions for savings, 37 in number, on the same date had 98,359 depositors and de-

posits to the amount of \$48,771,501 86. The aggregate assets amounted to \$50,540,703 19. The condition of the Rhode Island Hospital trust company in Providence, the only one in the state, was as follows: capital, \$500,000; deposits, \$1,935,520 59; moneys in trust, \$3,696,344 43; total assets, \$6,694,862 65. The following are the statistics of the fire, fire and marine, and life insurance companies authorized to transact business in the state on Jan. 1, 1875:

COMPANIES.	Number.	Capital paid up.	Gross assets.	Liabilities, including reinsurance.	Surplus as to policy holders.
Fire, &c. { Rhode Island companies.....	23	\$1,300,000	\$3,103,200	\$1,272,271	\$1,580,929
{ Companies of other states.....	102	32,132,270	79,720,055	31,966,194	47,753,861
{ Foreign companies.....	13	14,595,821*	7,204,276*	7,391,044*
Life companies of other states.....	31	4,476,000	331,073,845	292,353,751	38,725,064

—The official designation of the state is "the state of Rhode Island and Providence Plantations." The government is vested in a governor (salary \$1,000), lieutenant governor

(\$500), secretary of state (\$2,500 and fees), attorney general (\$2,500), treasurer (\$2,000),

* In the United States.

and a general assembly consisting of a senate and house of representatives. They are all elected annually by the qualified voters on the first Wednesday of April. An auditor (salary \$1,500) is chosen annually by the general assembly. The senate consists of the lieutenant governor and one member from each city and town in the state. The governor, and in his absence the lieutenant governor, presides, voting only in case of a tie. The secretary of state is *ex officio* secretary of the senate. The house of representatives cannot exceed 72 members, apportioned among the cities and towns according to population after each census; but each town is entitled to at least one representative, and none can have more than 12; the latter number is sent by the city of Providence. The pay of the members is \$1 a day and 8 cents for every mile travelled. The present number of senators is 36 and of representatives 72. Rhode Island has two capitals, Providence and Newport, the general assembly holding annually its regular session in the latter city commencing on the last Tuesday of May, and a session by adjournment in the former. The pardoning power is vested exclusively in the governor, with the advice and consent of the senate. The judicial power is vested in a supreme court and courts of common pleas. The supreme court has general appellate and original jurisdiction, and consists of a chief justice, with a salary of \$4,500, and three associate justices with salaries of \$4,000 each; they are elected by the general assembly, and hold office until removed by a resolution of both houses. The court of common pleas in each of the five counties is held by a single judge of the supreme court. It has jurisdiction of appeals from justices' and other inferior courts, of crimes not punishable by imprisonment for life, and of civil cases involving \$100 and upward, or the title to real estate. Justices' courts are held in each town and city by a trial justice selected from the qualified justices of the peace. The town councils are courts of probate within their respective towns, though in each a special judge of probate may be elected, who then has exclusive jurisdiction of probate matters. In the city of Providence the municipal court is the court of probate. Voters must be male citizens of the United States 21 years old and upward. Naturalized citizens must also be possessed of a freehold of \$184 or renting for \$7 per annum, and have resided one year in the state and six months in the town or city in which they offer to vote. Native-born citizens may vote upon the same qualifications; they may also vote, without the property qualification, if they have resided two years in the state and six months in the town or city, have been registered on or before the last day of December preceding the election, and have within a year paid taxes amounting to \$1 or served at least one day in the militia. But no person can vote "upon any

proposition to impose a tax, or for the expenditure of money in any town or city, unless he shall, within the year next preceding, have paid a tax assessed upon his property therein, valued at least at \$134." The distinction between native and naturalized citizens is not expressly stated in the constitution, but rests upon a reference in that instrument to the act calling the convention to frame it. The voting for general state officers and for representatives in congress must be by ballot; voting for senators and representatives in the general assembly and for town or city officers is by ballot when demanded by any seven persons entitled to vote for those officers. In all elections a majority of all the electors voting is necessary to a choice. If there be no choice for governor or other state officers, the election is made by the general assembly in joint session from the two candidates having the greatest number of votes. In the case of senators and representatives, a new election is held by the people until some candidate receives a majority. Amendments to the constitution must be adopted by a majority of all the members elected to each house of two successive legislatures, and subsequently by a three-fifths vote of the people. Rhode Island is entitled to two representatives and in common with the other states to two senators in congress, and has thus four votes in the electoral college.—The valuation of the real and personal property of the state according to the federal censuses has been as follows:

YEARS.	ASSESSED VALUE.			True value of real and personal estate.
	Real estate.	Personal estate.	Total.	
1850....				\$80,508,794
1860....	\$83,778,204	\$41,326,101	\$125,104,305	135,337,583
1870....	132,876,581	111,402,273	244,278,854	296,965,646

The total taxation not national in 1870 was \$2,170,152, of which \$489,253 was state and \$1,680,899 town, city, &c.; total public debt, \$5,938,642, of which \$2,913,500 was state and \$3,025,142 town, city, &c. The receipts and payments into and from the state treasury during the year ending April 30, 1875, were as follows:

Balance in treasury May 1, 1874.....	\$294,300 63
RECEIPTS.	
State tax	\$492,418 77
Institutions for savings.....	112,923 17

Balance in treasury April 30, 1875.....		\$475,850 23

The funded debt of the state at the above date amounted to \$2,563,500.—The state institutions are the state prison in Providence, and the workhouse and house of correction, the state asylum for the incurable insane, and the state almshouse on the state farm (418 acres) in Cranston. The state prison and Providence county jail (on the same premises) are under the management of a board of seven inspectors appointed annually by the governor, who serve without pay. The labor of the prisoners is let to contractors, and is employed in the manufacture of furniture and wire goods and in chair seating. The number of convicts in prison during the year ending Jan. 1, 1875, was 101; remaining on that date 67; number of persons in jail during the year, 2,618; remaining at the close, 147. The receipts of these institutions amounted to \$23,428 93, of which \$14,715 42 were from labor; ordinary expenses, \$22,967 46. The institutions on the state farm are under the management of a board of state charities and corrections, consisting of six members appointed by the governor and senate for six years (one retiring annually). These serve without pay, and appoint a secretary, who is *ex officio* a member of the board. The board appoints a superintendent of state charities and corrections. The state almshouse, for paupers not having a legal settlement in any town, was opened on Aug. 1, 1874. The following statistics are for the year ending Jan. 1, 1875:

INSTITUTIONS.	Inmates during year.	Inmates at close of year.
Workhouse and house of correction.....	735	199
Asylum for incurable insane.....	207	172
Almshouse (five months).....	196	141

Of the insane in the asylum on Jan. 1, 1875, 62 were supported wholly by the state; the board of the others was paid by the towns or by friends of the patients at from \$2 to \$4 per week. The average number of paupers in the town asylums during the year ending June 1,

1874, was 472, and they were supported at the cost of \$32,082 89, exclusive of the income of the farms connected with the asylums. The Butler hospital for the insane in Providence is a corporate institution, but some poor patients are supported at the expense of the state or of the towns. It was opened in 1848. A fine farm is connected with it. The number under treatment during 1874 was 234; remaining at the close of the year, 127. The greater number are supported from private means. The number of public patients during the year was 40, at the close 16; toward the maintenance of these \$1,630 18 was paid by the state and \$1,817 28 by the towns. The entire net expenditure of the institution was \$55,217 44. The Providence reform school is a city institution, but it receives children and youth from all parts of the state. It was opened in 1850. The number of inmates during the year ending Nov. 30, 1874, was 369 (314 boys and 55 girls); remaining on that date, 220 (179 boys and 41 girls). The receipts during the year were \$41,699 79, of which \$20,955 71 were from the state; expenditures, \$41,295 38.—The public schools are under the management of a board of education, consisting of the governor and lieutenant governor *ex officio*, and six members elected by the general assembly for three years (two retiring annually). The members serve gratuitously. The board elects annually a commissioner of public schools (salary \$2,500), who also acts as its secretary. A school committee, varying in number, is elected in each town by the qualified voters for three years. Women are eligible to the committees. There is a board of trustees for each district, elected by the qualified voters. The schools in the city of Providence are governed by ordinances and regulations adopted by the city authorities. The public schools are free, and are supported by state, town, and district taxes. The following are the statistics for 1873-'4:

Number of school districts.....	429
“ of day schools.....	732

More than half of the schools are graded. The following cities and towns have high schools, or schools of an equal grade, either public or private: Providence, Newport, Woonsocket, Pawtucket, Bristol, Warren, Westerly, Lincoln, East Greenwich, Barrington, Scituate, and East Providence. Children under 15 years of age employed in manufactories are required to attend school at least three months in the year. The state normal school is in Providence. Tuition is free to such as intend to teach in the public schools of the state. The number of instructors is 8; number of pupils in 1873-'4, 141. The most important institution of learning in the state is Brown university at Providence, founded in 1764. By a legislative act of 1862 it received the congressional land grant of 120,000 acres for the establishment of a college of agriculture and the mechanic arts. This has been sold for \$50,000, and entitles the state to the gratuitous tuition of 30 students in those branches. In 1874-'5 the university had 11 professors, 4 instructors, 253 students, and a library of upward of 40,000 volumes. (See BROWN UNIVERSITY.) The number of libraries, according to the census of 1870, was 759, with 693,387 volumes, of which 425, with 383,691 volumes, were private, and 334, with 309,696 volumes, not private, viz.: 1 state, 1,500 volumes; 10 town, city, &c., 15,198; 5 court and law, 2,147; 12 school, college, &c., 97,500; 248 Sabbath school, 116,441; 26 church, 11,160; 32 circulating, 65,750. There were 32 newspapers and periodicals, having an aggregate circulation of 82,050, and issuing 9,781,500 copies annually, viz.: 6 daily, circulation 23,250; 1 semi-weekly, 1,200; 19 weekly, 43,950; and 6 monthly, 13,650. The statistics of churches, according to the census, are as follows:

—Geographers have recently fixed upon Rhode Island as the ancient Vinland, said to have been discovered by the Northmen about A. D. 1000 (see NORTHMEN); indeed, if reliance is to be placed on the Icelandic sagas, a critical examination of them leads to this result. In 1524 Verrazzani, coasting eastward from a bay which has been identified as that of New York, passed up an opening into a large bay where he remained a fortnight. There is little doubt that this was Narragansett bay, and that he first came to anchor in Newport harbor. He held a friendly intercourse with the natives, who visited his vessel in great numbers. The country was then very thickly populated. Many have believed that the "old stone mill," an interesting ruin in Newport, long the puzzle of antiquaries, was the work of some of the early European navigators who followed Verrazzani, while the Danish antiquaries claim it as a work of the Northmen. It was used for a grist mill by the settlers who accompanied Williams and Coddington to Rhode Island, and was probably erected by them for that purpose. The celebrated Dighton rock, on Taunton river, a few miles from Mt. Hope bay, bearing a variety of strange figures, has been claimed by the Danish antiquaries as a memorial of the visit of the ancient Northmen under Thorfin in the 10th century. They have even gone so far as to attempt to trace out the name of this hero among the rude sculptures on the rock. Rhode Island was first settled at Providence (so called in grateful acknowledgment of "God's merciful providence to him in his distress") in the year 1636 by Roger Williams, who had been banished from Massachusetts for maintaining opinions in political and religious matters at variance with those of the rulers in that colony. He immediately put into practice the doctrine of liberty of conscience. In 1638 William Coddington and some others, who were also persecuted and forced to leave Massachusetts for religious opinions, deemed to be heresies there, purchased from the Indians the island of Aquidneck or Aquiday, afterward called Rhode island, and effected a settlement there, from which sprung the towns of Newport and Portsmouth. A third settlement was formed at Warwick in 1643, by a party among whom John Greene and Samuel Gorton were prominent. The same year Williams went to England and obtained a patent for the united government of the settlements, dated March 14, 1643-'4, which did not go into operation till 1647. This patent remained in force till 1663, when a charter was obtained from Charles II., incorporating the colony of "Rhode Island and Providence Plantations," which was the only constitution of government for 180 years. The great war between the English settlers and the Indian tribes of New England broke out in June, 1675. Rhode Island suffered severely from it. Many towns, villages, and farm houses were burned, and families

butchered. Providence, among others, was burned. The war only terminated with the death of Philip, king of the Wampanoags, a powerful tribe which dwelt on the eastern shore of Narragansett bay, in August, 1676. But the great contest in this war, and which decided the fate of the Indians, took place in December previous in the "Narragansett country," so called, in the S. part of the state, the seat of the great and powerful tribe of Narragansetts. Here the Indians had collected in great numbers and fortified themselves, on a rising ground in the centre of a dense swamp. A considerable force was sent against them from Massachusetts, Plymouth, and Connecticut. The Indians were defeated with great loss, many perishing in the flames that destroyed their village. The loss of the colonists was also severe. Rhode Island was opposed to this exterminating war, and was not even consulted in regard to it by the other colonies. In January, 1687, Sir Edmund Andros, having been commissioned as governor of New England, New York, &c., abrogated the charter of Rhode Island, with those of other colonies, which then became a mere county, governed by civil officers appointed by him, till he was seized and sent to England in 1689. Rhode Island took a prominent part in the struggle between Great Britain and France for empire in America. She furnished large numbers of troops for the expeditions against Louisburg, Crown Point, Oswego, and Canada; but it was on the ocean that she rendered the most important service. In 1756 she had 50 privateers at sea, manned by upward of 1,500 men, which cruised along the coast and among the West India islands, making many captures. In the war of the revolution the first naval squadron sent against the enemy was fitted out and sailed from Providence under command of Commodore Hopkins, who was styled admiral. Commodores Whipple and Talbot also sailed from and belonged to Rhode Island. Gen. Nathanael Greene was a native of and began his military career in this state. In December, 1776, Rhode Island was invaded by the British, who occupied Newport several years. Gen. Sullivan, aided by a French fleet under Count d'Estaing, made several unsuccessful attempts to dislodge the enemy, and in the autumn of 1778 laid siege to Newport, but was finally obliged to abandon the project. Toward the close of 1779 the British troops were withdrawn, and the following year Rochambeau arrived with 6,000 French auxiliaries. Rhode Island was the last of the thirteen colonies that accepted the constitution of the United States, her assent being given on May 29, 1790. In the war of 1812 with Great Britain the state was made conspicuous by the victory on Lake Erie of Commodore O. H. Perry, a native of this state, won by the aid of a party of seamen and shipwrights from Rhode Island. Under the charter as in force at the breaking out of the revolution the low-

er house of the legislature consisted of six deputies from Newport, four each from Providence, Portsmouth, and Warwick, and two from each of the other towns. The right of suffrage was restricted to owners of a freehold worth £40 or \$134, or renting for 40s. or \$7 a year, and to their eldest sons. In process of time the property qualification and the inequality of representation, which continued to increase, caused much dissatisfaction. In 1840 Providence with only four representatives had 23,171 inhabitants, while Newport with six representatives had only 8,333 inhabitants. Of the 72 representatives elected in that year, 38 were chosen from towns having only 29,026 inhabitants and 2,846 voters, while the remaining 34 were chosen from towns having 79,804 inhabitants and 5,776 voters. Various attempts to obtain reform from the legislature having failed, suffrage associations were organized in the latter part of 1840 and the early part of 1841, which, at a mass convention held at Providence on July 5 of the latter year, authorized their state committee to call a convention to frame a constitution. Delegates were elected on Aug. 28, and on Oct. 4 the convention assembled at Providence. A constitution was framed and submitted to the people on Dec. 27, 28, and 29, when, it was asserted, about 14,000 votes were cast for its adoption, being a majority of the adult male citizens of the state. It was also asserted that a majority of those entitled to vote under the charter voted in its favor. An election for state officers under this constitution was held on April 18, 1842, when Thomas Wilson Dorr, the most prominent leader in the movement, was chosen governor. On May 3 Mr. Dorr's government attempted to organize at Providence and to seize the reins of power. They were resisted by the legal state government, at the head of which was Gov. Samuel W. King. On May 18 a portion of the suffrage party assembled at Providence under arms, and attempted to seize the arsenal, but dispersed on the approach of Gov. King with a military force. They assembled again to the number of several hundred, June 25, at Chepachet, 10 m. from Providence, but upon the approach of the state forces they dispersed without resistance, and the affair was over on the 28th. Mr. Dorr was arrested, tried, and convicted of high treason, and on June 25, 1844, sentenced to imprisonment for life. In 1847 he was released under an act of general amnesty, and in 1851 he was restored to his civil and political rights. In 1854 an act was passed to reverse and annul the judgment in his case, on the ground that the proceedings against him had been illegal and unjust; but the supreme court subsequently declared it unconstitutional, as an assumption of judicial authority by the legislature. In the mean time the legislature on Feb. 6, 1841, called a convention to frame a new constitution. The delegates were elected in August, and the con-

vention assembled in November and adjourned to February, 1842, when they agreed upon a constitution, which was submitted to the people on March 21, 22, and 23, and rejected. In June the legislature called another convention, which met at Providence in September and subsequently adjourned to East Greenwich, where on Nov. 5 it agreed upon the present constitution, which was ratified by the people almost unanimously. It went into effect on the first Tuesday of May, 1843. In 1861 a controversy respecting the boundary with Massachusetts, transmitted from colonial times, was settled by the cession on the part of Rhode Island of that portion of the town of Tiverton containing the village of Fall River, in exchange for the town of Pawtucket and a part of Seekonk (now known as East Providence). In 1861 Rhode Island sent off a body of troops for the defence of Washington three days after President Lincoln issued his call for troops. During the war she furnished 23,711 men to the federal armies, equivalent to 17,878 for three years. (See supplement.)

RHODES (ancient and modern Gr. *Rhodos*, from *ῥόδον*, a rose). **I.** An island of Turkey in the Mediterranean, off the S. W. coast of Asia Minor, from which it is separated by a channel 10 m. wide. It is between lat. 35° 50' and 36° 30' N., and lon. 27° 40' and 28° 20' E.; area, about 452 sq. m.; pop. about 34,000, of whom about 7,000 are Turks, 2,000 Jews, and the remainder Greeks, with a few hundred Franks or Europeans. It is ruled by a pasha, who holds office for life, governing also the adjoining islands belonging to Turkey, and who farms the revenues. It is the seat of an archbishop of the Greek church. The island is divided lengthwise, N. and S., by a mountain chain or ridge. The loftiest summits are Artamiti, the ancient Atabyris, about 6,000 ft. high, and Attairo, 4,000 ft. The most considerable river is the Fisco. The well watered and fertile valleys are not fully cultivated. Some cotton is grown, and a tract of low hills next to the coast district still produces the perfumed wine for which the island was once celebrated. The climate is said to be the finest in the Mediterranean. Commerce is carried on in oil, oranges, citrons, coral, sponges, leather, and marble.—The earliest historical inhabitants of Rhodes were of Doric race, and the three most ancient towns of the island, Lindus, Ialysus, and Camirus, formed, together with Cos, Cnidus, and Halicarnassus on the mainland, the confederation called the Doric hexapolis. At a remote period Rhodes was populous and prosperous. It was one of the stations of Phœnician commerce, and though in a state of decadence at the time of the fall of Sidon, it continued for several centuries to be one of the principal centres of trade, and sent colonies to Spain, Italy, and Sicily, as well as to the coasts of Asia Minor. In conjunction with Asiatic Greeks and Cnidians, the Rhodians established in 578 B. C. a colony on the N. E.

coast of Spain, to which was given the name of Rhoda (now Rosas.) The island did not take a prominent position among the Grecian states till 408, when the three cities before named joined in building the city of Rhodes, which thenceforth became the capital. The island fell under the dominion of Alexander the Great, but after his death the Macedonian garrison was expelled, and Rhodes entered upon the most glorious epoch of her history, during which her power was admitted by all the surrounding nations, and her dominion, in consequence of her alliance with Rome against Antiochus the Great and others, established for a time over a portion of the adjacent coast of Asia Minor. The Rhodians remained faithful to Rome during the Mithridatic wars, entered actively into her civil wars, and their adhesion to the party of Cæsar was severely punished by the capture and plunder of the city of Rhodes in 42 B. C. From this period the island rapidly declined in political power, though it long continued to be famous as a seat of learning. It was finally deprived of its autonomy by the emperor Vespasian. In 330 the city was made the metropolis of the Provincia Insularum. Upon the ruin of the empire of the East the island fell successively into the hands of the caliphs, the crusaders, and the Genoese; and in 1309 the knights of St. John of Jerusalem, who had been compelled to evacuate Palestine, landed at Rhodes, and under the grand master Foulque de Villaret vanquished the Moslems and Greeks in several encounters, and made themselves masters of the city and the island. The knights held the place for two centuries, and in 1522 Sultan Solymán the Magnificent advanced against it with an army numbering upward of 200,000. There was on the island to oppose this only a force of 6,000, headed by the grand master Villiers de l'Isle-Adam. After a siege that lasted through the whole summer, almost innumerable assaults, and a most heroic defence, the city capitulated in October, and has ever since remained under its present masters. The surviving defenders were allowed to leave the island. (See SAINT JOHN OF JERUSALEM, KNIGHTS OF.) Rhodes has many times been visited by earthquakes; that of April 22, 1863, ruined hundreds of dwellings and destroyed thousands of lives. There are now on the island about 44 villages, thinly populated. **II.** The chief city and capital of the island, on the N. E. coast; pop. about 20,000, Turks, Greeks, and Jews. It is built in the form of an amphitheatre upon a bay between two capes, and is surrounded by ancient walls and towers built by the knights of St. John. There are two harbors, separated by a narrow quay. The palace of the grand master was a large and handsome building and commanded the city; it was much injured by the explosion of a powder magazine in 1856, and the earthquake of 1863 completely destroyed it, as well as the once magnificent church of St. John, then a

Turkish mosque. There are no considerable remains of an earlier time than the residence of the knights of St. John, among which is a moated castle of great size and strength, containing the cloisters of the knights. The city of Rhodes, which in 304 B. C. withstood a

famous siege by Demetrius Poliorcetes, is described by Strabo as superior to all other cities for the beauty and convenience of its ports, streets, walls, and public edifices, all of them profusely adorned with works of art. There are said to have been about 3,000 statues in

Rhodes, from the hill northwest of the city.

the city. It contained one of the seven wonders of the ancient world in its brazen statue of Apollo, commonly called the colossus of Rhodes. (See *COLOSSUS*.)

RHODES, Inner and Outer. See APPENZELL.

RHODEZ. See RODEZ.

RHODIUM, a metal belonging to the platinum group, discovered by Wollaston in 1803. He found 0.4 per cent. in ore from Brazil, and in a specimen from another locality as much as 3 per cent. It usually forms about one half of one per cent. of the ore. It may be extracted from the solution from which platinum and palladium have been separated in the manner which has been described. (See *OSMIUM*, *PALLADIUM*, and *PLATINUM*.) The solution is mixed with hydrochloric acid and evaporated to dryness, and the residue is treated with alcohol of sp. gr. 0.837; this dissolves everything except the double chloride of sodium and rhodium, which remains behind as a red powder. This is dissolved in water, and the rhodium precipitated by the action of metallic zinc, or the salt may be reduced by heating it in a current of hydrogen gas. Rhodium is white and very hard. When quite pure it is malleable after fusion upon lime, and is then of sp. gr. 12.1. Wollaston's estimate was 11, but he experimented on the unfused metal. The fusing point of rhodium is higher than that of platinum, and it will only melt in the voltaic arc

or in the oxyhydrogen furnace; the precise degree cannot be estimated. Its symbol is Ro; its atomic weight 104 or 104.3. It is unalterable in the air at ordinary temperatures, but oxidizes, and also combines with chlorine, at a red heat. It resists the action of the strongest acid, singly or combined, unless alloyed with some other metal, when it will dissolve in nitro-muriatic acid. Rhodium forms four oxides: a monoxide, RoO ; a sesquioxide, Ro_2O_3 ; a dioxide, RoO_2 ; and a trioxide, RoO_3 . The principal oxygen salts are the acetate, nitrate, phosphate, sulphate, and sulphite. There are two sulphides, RoS and Ro_2S_3 . According to Berzelius, there are three chlorides, RoCl_2 , Ro_2Cl_3 , and RoCl_3 ; but more recent investigations by Claus make it probable that there is only one, the trichloride, RoCl_3 , which forms double chlorides with the alkalis. The best known salt of rhodium is the sodic rhodic chloride, which is obtained in the extraction of the metal as described above. The rhodic salts generally form rose-colored solutions, and are decomposed by metallic iron or zinc, with precipitation of metallic rhodium. Potassic and sodic hydrates added to rhodic salt solutions slowly precipitate a yellow hydrated rhodic oxide, which is soluble in excess of alkali as well as in acids. Potassic iodide precipitates a sparingly soluble yellow tri-iodide of rhodium. Sulphuretted hydrogen in hot

solutions slowly forms a brown sulphide. Rhodium salts heated in a current of hydrogen gas are reduced to the metallic state.

RHODODENDRON (Gr. *ῥοδὸδένδρον*, rose tree, the ancient name), a genus of plants of the order *ericaceæ* or heath family, to which the name rose bay has been given, but the botanical name is in more common use. The rhododendrons are shrubs or low trees with evergreen, entire, alternate leaves, and (usually) large showy flowers in close terminal clusters, from large scaly-bracted buds. The bell-shaped or funnel-shaped corolla is five-lobed, and often somewhat irregular; the ten stamens (rarely less) are usually declined or bent downward, as is the elongated style; anthers short, opening by terminal pores; pod five-celled, five-valved, and many-seeded. The genus is widely distributed, some species occurring in the arctic zone, others in the temperate portions of North America, still others in Europe and China, while in the mountains of India they are very numerous. Four species are found east of the Mississippi, one of which, the Lapland rhododendron (*R. Lapponicum*), belongs to the arctic flora of both continents, and with us is found only on the alpine summits of the mountains of Maine, New Hampshire, and New York; it is a little, dwarf, prostrate species, with branches only a few inches long, its stems and leaves dotted with rusty scales; the flowers are open, bell-shaped, violet purple and dotted. The great rhododendron (*R. maximum*), also called great laurel, is found sparingly from Maine to Ohio, but is very common in the mountains of the

Hybrid of *Rhododendron Catawbiense*.

middle states, and along the watercourses as far south as Georgia; it flourishes best in deep, damp woods, and in cedar swamps it often forms the principal undergrowth. It is from 6 to 20 ft. high, with the habit of a shrub rather than of a tree. The leaves are

very thick and leathery, from 4 to 10 in. long, elliptical-oblong, acute, narrowed toward the base, somewhat revolute or turned over on the margins, very smooth, and dark green. The flowers appear in July in large clusters, with somewhat viscid stalks; the corolla is an inch broad, white or pale rose-colored, and greenish at the throat on the upper side and spotted with yellow or reddish dots; a variety is sometimes met with having pure white and one with purplish flowers. This species is not common in cultivation, and succeeds best in a shaded situation; some hybrids have been produced from it, but very few in number compared with those from the next. The *Catawba rhododendron* (*R. Catawbiense*) grows on the higher Alleghanies from Virginia to Georgia. It is a compact shrub, from 3 to 6 ft. high; its oval or oblong leaves are rounded at both ends, pale beneath, and 3 to 5 in. long; the broadly bell-shaped flowers are lilac purple, and on (usually) rusty-downy stalks. This species, hybridized with tender exotic species, is the original of the fine ornamental rhododendrons to be mentioned presently. The dotted rhododendron (*R. punctatum*) completes the list of the eastern native species; this is found from the mountains of North Carolina southward, a small-leaved form occurring in West Florida. It grows 4 to 6 ft. high, has leaves 2 to 4 in. long, and, though evergreen, thinner than in the other species, and their lower surface, as well as branchlets, and outside of the flowers, sprinkled with rusty dots; the flowers are rather small and rose-colored.—Two species, both first described and figured by Sir William Hooker, occur in the far west. The white-flowered rhododendron (*R. albiflorum*), first found on the Rocky mountains, and since on the Cascade range, is a low shrub with drooping cream-colored flowers, unlike those of others in appearance. The Californian species (*R. Californicum*), from the mountains of California, has proved hardy in England, and is described as of moderate size, good habit, and having very showy rose-colored flowers.—The most important exotic species is the Pontic rhododendron (*R. Ponticum*), from Pontus in Asia Minor; it is sometimes 20 ft. high, but usually less than half that height. Its obovate-lanceolate leaves taper to the base, and its large, very open bell-shaped corolla is purple, opening in early spring. This is the common rhododendron of European gardens, and, though not generally hardy in our northern states, sometimes succeeds if kept as a low bush and given a slight protection, without which its flower-buds will be winter-killed. Its chief use in this country is to furnish stocks upon which to graft hardier kinds, as it grows readily from seeds. In Europe it has produced a number of varieties, some of which are harder than the species. The tree rhododendron (*R. arboreum*) is a noble species from Nepaul, and still more tender than the Pontic; the dark green leaves

are silvery white beneath, and the large clusters of flowers are scarlet, varying, even in the wild state, through various shades to pure white. The catalogue of varieties is a long one, but they can only be cultivated in the northern states, as in England, under glass, where, when room can be afforded, they make a most brilliant show. Other exotic species seen in rare collections are the yellow-flowered (*R. chrysanthum*), from the Caucasus; the hairy (*R. hirsutum*), very dwarf, with pale red flowers; and the Daurian (*R. Dauricum*), from Siberia, a dwarf species with bright rose-purple and very early flowers; these three are hardy. A magnificent group of rhododendrons is found in the Himalaya, presenting a great variety in foliage and flowers, as well as habit of growth, some of them being epiphytes; they require to be cultivated under glass, both here and in Europe; the majority of these were first made known by Dr. J. D. Hooker, to whose work, "The Rhododendrons of the Sikkim Himalaya," reference may be made for descriptions and colored plates of these wonderfully beautiful plants.—The rhododendrons of our gardens are known as hybrids of *R. Catawbiense*; European horticulturists have long practised hybridizing this species with *R. arboreum*, *R. Ponticum*, and possibly others; among these hybrids are many very beautiful varieties which do not endure northern winters, requiring to be housed; but there are several perfectly hardy varieties, which some experienced cultivators think are not hybrids at all, but merely seedling variations of *R. Catawbiense*. Especial attention is given to these plants in England, and their popularity in this country is increasing. For beauty of form and foliage and profusion and variety in flowers no other shrubs can equal them. Their general cultivation has been hindered by the supposition that they require a peat soil; but the plants, at least those raised in this country, will flourish perfectly well in any good garden soil that is not calcareous; they will not succeed in a heavy clay or on a limestone soil. The varieties are numbered by hundreds; twelve well tested sorts are: *grandiflorum*, *album elegans*, *roseum elegans*, *Everestianum*, *album grandiflorum*, *giganteum*, Lee's dark purple, *gloriosum*, *macranthum*, *purpureum elegans*, *candidissimum*, and *speciosum*. The rhododendrons are exceedingly manageable plants; they may be taken up at almost any time without injury, and when in full bloom may be lifted and used for the decoration of rooms, and set out again without showing the effects of the disturbance. In England the commoner seedlings are largely planted to form game coverts.—But little positive is known about the active properties of our native rhododendrons; narcotic powers are attributed to *R. maximum*, while others regard it as a simple astringent; Michaux says that *R. punctatum* yields a honey that is deleterious, but this

statement needs confirmation. The information in regard to exotic species is hardly more definite; the yellow-flowered rhododendron is said to be narcotic and dangerous. In India the natives eat the flowers of *R. arboreum*, and European residents prepare a conserve from them; this species secretes honey in such quantities that when the bush is shaken it falls like rain in large drops.

RHODOPE. See THRACE.

RHODORA (Gr. ῥόδον, a rose, from the color of the flowers), a native shrub of which the botanical and common names are the same. *R. Canadensis* is the only species, and is by some botanists appended to *rhododendron*, from which it differs in its deciduous leaves and its very irregular flowers, the corolla being two-lipped, the upper lip three-lobed, and the lower two-parted, or of two distinct spreading petals. The shrub is 1 to 3 ft. high, with copper-colored stems and oblong leaves,

Rhodora Canadensis.

revolute on the margin, pale glaucous green above, and whiter and downy beneath. The flowers, in umbel-like clusters, or little tufts, at the ends of the branches, appear just before the leaves, and are of a bright rose-purple and showy; occasionally white-flowered specimens are met with. It is found from Pennsylvania to New England and northward and eastward; it sometimes grows in damp cold mountain woods, but more abundantly in wet marshes, where, especially in the vicinity of Boston, it sometimes covers acres in April or May, with its bright yet modest bloom. Like many other plants, which when growing wild are always found in very wet places, the rhodora succeeds well when transferred to ordinary garden soil, and is a shrub eminently worthy of cultivation.

RHÔNE (anc. *Rhodanus*), a river of Europe, rising in the N. E. corner of the Swiss canton of Valais, not far from the sources of the Rhine, and flowing into the gulf of Lyons in

the Mediterranean sea by two mouths, after a circuitous but general W. and S. course of about 600 m., 350 of which are in France. It originates at the foot of the Mayenwand, on the W. side of the St. Gothard, near the Furca pass, but can scarcely be called a river until its junction with several other streams at the bottom of the Rhône glacier, about 5,500 ft. above the sea. Thence it traverses Valais in a S. W. and then N. W. direction as a mountain torrent, passing by Sion, till it enters the lake of Geneva near its E. extremity, where it has descended upward of 4,000 ft. In this part of its course it receives many small tributaries, the most important of which is the Dranse. When the Rhône enters the lake of Geneva its waters are exceedingly turbid; but on issuing from the S. W. extremity of that lake the river is of a clear blue color, which, however, is changed to brown by the accession of the Arve, a muddy stream, about 1½ m. below Geneva. It flows S. W. for about 15 m. till it enters France, when it turns S. through a narrow pass between the Alps and the Jura. A little way below this place is the Perte du Rhône, where the river descends into a deep chasm partly covered over with massive fragments of rock. The Valsérine, a fine stream from the Jura, joins here from the right. At St. Genix, where the Rhône receives the Guiers from the south, it turns abruptly N. W. and afterward more to the west, till it reaches Lyons, receiving during this part of its course the Ain from the north; and at Lyons it is joined by the Saône, also from the north. The Rhône is here a considerable river, and flows almost due S. to Arles, through a beautiful and fertile country, but the rapidity of the current and the shifting sands in its bed render navigation dangerous and tedious. The most important tributaries in this part of its course, from the Cévennes on the right, are the Doux, Ardèche, Cèze, and Gard; and on the left, from the Alps, the Isère, Drôme, and Durance. At Arles the river separates into two branches, the principal one, called the Grand Rhône, flowing S. E. to the sea, while the other, called the Petit Rhône, flows S. W., enclosing between them the deltoid island of Camargue. The Grand Rhône enters the gulf of Lyons below the Tour St. Louis, and has there commenced the formation of a new delta; and the Petit Rhône has its mouth a little W. of the village of Saintes Maries. Both these mouths are so much obstructed by bars, that vessels from the Mediterranean enter the river by the Étang de Berre, a shore lake or lagoon to the east, which is connected with the Rhône by the Martigues canal, and by the Beaucaire canal, which leads from Arles to the lagoons to the west on the coasts of the departments of Gard and Hérault. Steamers sometimes ascend the Rhône as far as Seyssel, and by means of the Saône it is navigated to Châlon; while by canals it is connected with the Garonne, Seine, Loire, and Rhine. The Rhône is of great

commercial importance, and below Lyons is navigated by numerous steamers. The Paris and Marseilles railway runs along its left bank between Lyons and Arles; and in this part of its course the river passes many considerable towns, the principal of which are Vienne, Tournon, Valence, Avignon, Beaucaire, Tarascon, and Arles. Some of the finest wines of France are produced on the banks of the Rhône below Lyons.

RHÔNE, a S. E. department of France, formed from the old province of Lyonnais, bordering on Saône-et-Loire, Ain, Isère, and Loire; area, 1,077 sq. m.; pop. in 1872, 670,247. The department is traversed in a N. and S. direction by a continuation of the Cévennes; Mont Tarare, the highest summit, is about 3,300 ft. above the sea. The Rhône and Saône form the E. boundary. The soil is not fertile, and only about half the surface is arable; the vine is grown, and some of the wines are excellent. It is divided into the arrondissements of Lyons and Villefranche. Capital, Lyons.

RHUBARB (Lat. *rha*, or *rheu barbarum*, a name given by the early writers), in medicine, the root alone of *rheum officinale* and some other species, but in horticulture the name of the plants of several species. The genus *rheum* (either from Gr. *ρῆν*, to flow, in reference to its purgative properties, or from *Rha*, the ancient name of the Volga, upon the banks of which it grew) belongs to Asia and southern Russia; and growing in localities from which Europeans have been excluded, there has been much confusion as to the species, of which according to Meisner there are about 20. They are all perennials, with large woody rootstocks, from which proceed radical leaves with long, thick petioles, the blade of the leaf usually very broad, entire, or variously lobed, and with strong palmate ribs; the annual stem is erect, large, and hollow, bearing smaller leaves, and spikes or panicles of flowers; all the leaves have large sheathing stipules, but those of the stem leaves are very conspicuous; the apetalous flowers have a white, greenish or pinkish, six-parted calyx; nine stamens; a triangular ovary, surmounted by three styles, and becoming a three-winged fruit. The common rhubarb of the gardens, or pie plant, as it is frequently called, is a familiar representative of the genus; this species, *R. Rhaponticum* (with several synonyms), a native of Siberia and the country along the Volga, was introduced into England as early as 1573, and in the time of Elizabeth its leaves were in use as a pot herb, like spinach. It is now cultivated in gardens solely for its acid petioles or leaf stalks, which are used as a substitute for fruit, a custom unknown until early in the present century. Coming early in spring (and they may be had by forcing at any time during the winter), at a season when fruit is scarce, the leaf stalks are in great demand; their consumption in England is even more general than with us. The rapidly grown stalks contain but little woody fibre,

and cook readily to a pulp, which with sugar is used for pies, tarts, and other culinary preparations; their acidity is due in part to oxalic, but more largely to malic acid, both acids being in combination with potash as acid salts; it disagrees with some, but its large consumption indicates that it is not especially deleterious. About 1860 great efforts were made to establish its use as a wine plant, but the product proved inferior, and was by many considered injurious. There are several garden varieties, as at one time many seedlings were raised with a view to produce plants with the greatest development of leaf stalk; the Cahoon has stalks 3 in. or more in diameter and often 2 ft. long, but it is coarse and harsh in flavor; the best variety is Myatt's Linnaeus, very early, of medium size, tender, and of excellent flavor; Tobolsk is a small kind, very early and good. For field culture the plants are raised in a seed bed, and when a year old are transplanted to 3 or 4 ft. each way; they yield the third year; small plantings are made by dividing the old roots into as many pieces as they have buds, and setting out the pieces; the soil can hardly be too rich. Rhubarb is readily forced by placing the plants in winter in boxes or barrels with earth in a warm cellar, or on a larger scale in frames. In the present style of sub-tropical gardening the rhubarbs are employed on account of their vigor of growth and pic-

are a yard across, and have red veins; this is cultivated in England by gardeners for the sake of its large leaves, which are used for covering baskets of fruit. The finest of all the species is the Himalayan (*R. nobile*), discovered by Dr. J. D. Hooker; it forms a pyramid a yard and more high, the base of which is of shining green leaves with red petioles and nerves, and the upper parts of delicate straw-colored bracts with pink edges.—Rhubarb as a drug has been known from very early times,

Medicinal Rhubarb (*Rheum officinale*).

and it is said to be treated of in a Chinese herbal written about 2700 B. C. European naturalists early endeavored to ascertain the exact species that produced the excellent kinds of rhubarb procured through Russia and Turkey, and distinguished by the name of either one of these countries. Several species of *rheum* have from time to time been regarded as furnishing the better sorts; it is probably produced by different species, one of which is *R. officinale*; this is much larger than the garden rhubarb, differing among other characters in having nearly cylindrical petioles, and the under side of the leaf being covered with short, erect hairs. Formerly the best variety was known as Turkey rhubarb, being brought by caravans from Tartary by way of Persia to the Levant ports, whence it reached Europe; but rhubarb from this source disappeared from the trade about a quarter of a century ago. A similar article entered commerce by way of Russia, and was known as Russian rhubarb. It was brought to the fron-

Himalayan Rhubarb (*Rheum nobile*).

turesqueness; an isolated plant of the common rhubarb is very effective, but the Nepal rhubarb (*R. Emodi*) is much finer; the leaves

tier town of Kiakhta, where it was rigorously inspected by the agent of the Russian government. Every piece of the root was perforated to the centre in order to prove its soundness, and all the defective pieces were destroyed; those accepted were sent to St. Petersburg. The roots were of irregular shape, and appear to have been sliced on the surface with knives, probably for removing the bark, and marked with the large holes going partly through which were made for inspection. On account of the superior quality of the Russian rhubarb it commanded a high price, and to secure this other varieties were made to imitate it. The opening of various ports in northern China, and the rebellion beginning in 1851, exerted a depressing influence on the trade at Kiakhta, and the Chinese being very willing to avoid the great severity of the Russian inspection, the quantity of rhubarb delivered there became so small that the rhubarb office was abolished in 1863, so that Russian rhubarb has become a thing of the past. Most of the rhubarb that comes to the United States is from China, shipped from Canton. Some of this is very good, though still inferior to the Russian. The roots are more cylindrical and smoother, as if scraped; they are not of so bright a color, and the powder has a reddish brown tinge. Defective pieces are mixed in with the best, and as all are usually powdered together the medicine must be of inferior efficacy. The Chinese sometimes attempt to give it the appearance of the Russian variety by cutting it into angular shapes, and filling up with powdered root, in order to conceal the little holes that have been made through the roots for suspending them on strings to dry. It is believed that both the Russian and Chinese come from the same regions in Chinese Tartary and China proper, but there being in the Chinese market no such stringent regulations about the preparation of the drug, the inferior qualities are sent there. The roots are allowed to grow six years before they are sufficiently mature; and after they are dug the bark is removed and the root cut in pieces for drying, which is done in the sun and by the aid of fire heat. Owing to the risk and expense of land transport, rhubarb was in ancient times considerably more costly than opium. It is now purchased for the European market chiefly at Hankow on the upper Yangtse. From 1866 to 1872 the average exports of rhubarb from Hankow were over 3,000 peculs (1 pecul = 133½ lbs.). The cultivation of rhubarb for its root has been attempted in various European countries, and was at one time carried on by order of the Russian government in southern Siberia; some is produced in Hungary, Moravia, and Silesia; in France the cultivation, which in former years was considerable, has ceased except in the neighborhood of Avignon and in a few other localities. In England the cultivation of rhubarb for commerce commenced about a century ago,

and is still continued, the product being known in our commerce; it was formerly called Crimean rhubarb, and is sometimes fraudulently sold as the Turkey drug; in England it is known as Banbury rhubarb, from the locality of the plantations. The root is simply pared, sliced, and dried in a kiln; though very handsome in appearance, English rhubarb is of very inferior character. The species is mainly the common garden rhubarb (*R. Rhaponticum*). The medicinal qualities of the root are much affected by soil and climate, and those species known to give a valuable drug in their native localities yield in the cooler and moister climate of Europe a much deteriorated product. The rhubarb as imported, while hardly subject to adulteration, varies greatly in quality, unsound and poor being mixed with the good, and the inferior pieces being covered with a yellow powder to conceal the surface. In the powdered state there is, as with other drugs, ample room for adulteration, and a large share of that sold is of inferior quality.—The taste of rhubarb is a bitter astringent, the smell aromatic, though to most persons disagreeable; when chewed it crackles in the teeth from the presence of minute crystals of oxalate of lime, and it imparts a yellow color to the saliva. The best sorts are recognized by the bright yellow color of the powder. Its chemical composition is very complicated, and chemists have failed to discover any peculiar principle in the drug which fully accounts for its purgative properties. Brandes found in 100 parts of Chinese rhubarb 2 of pure rhubarbaric acid, 7·5 of the same impure, 2·5 of gallic acid, 9 of tannin, 3·5 of coloring extractive, 11 of uncrystallizable sugar with tannin, 4 of starch, 14·4 of gummy extractive, 4 of pectic acid, 1·1 of malate and gallate of lime, 11 of oxalate of lime, 1·5 of sulphate of potassa and chloride of potassium, 1 of silica, 0·5 of phosphate of lime and oxide of iron, 25 of lignine, and 2 of water. The analyses of Schlossberger and Döpping are still more elaborate, introducing a variety of new principles, among which the chrysophanic acid, resembling the rhubarbaric acid of Brandes, is the most interesting. It is a beautiful yellow substance, emitting yellow vapors when heated, soluble in alcohol, its alkaline solution of a fine red color, and those with potassa changing by evaporation to a violet and then to blue. It is a purgative, but less powerful than rhubarb itself. Magnificent purples also are obtained from the yellow coloring matter produced by treating rhubarb with nitric acid and then with alkalies; and it has been proposed to apply these, called erythrose, in the arts as a dyestuff. The still more recent examinations of Kubly (1867) do not materially change the aspect of the question.—The medical properties of rhubarb are very peculiar. Its first effects upon the system are cathartic, and to these succeeds an astringent action, checking the excessive operation of the purgative. The medicine is at the same time

tonic and stomachic. As a purgative its action is moderate, and affects rather the muscular fibre than the secretory vessels. Its use is obviously indicated for relaxed conditions of the bowels, when the stomach is enfeebled, and a gentle cathartic is required, as in certain cases of dyspepsia, diarrhœa, dysentery, &c. It is much used in combination with magnesia, calomel, and other cathartics, when greater purgative action is required. This action may be reduced by roasting or long boiling. It is exhibited in powder, sometimes made into pills with soap, also in infusion, sirup, and tincture.

RIAD. See RİYAD.

RIANZARES, Duke of. See MUÑOZ.

RIAZAN, or Riezan. I. A central government of European Russia, bordering on Vladimir, Tambov, Tula, and Moscow; area, 16,249 sq. m.; pop. in 1870, 1,477,433. The most important river is the Oka, which enters it in the north, and is connected with the Don by the Upa and the Ivanov canal. The soil is fertile in the south, but marshy in the north. There are extensive pastures; the principal products are grain, fruits, hops, and tobacco. The inhabitants are nearly all Russians, but there are a few Mordvins and Tartars. There are manufactories of coarse linen and woollen goods and of glass and iron. II. A city, capital of the government, on the Oka, 110 m. S. W. of Moscow, with which it is connected by rail; pop. in 1867, 17,950. It is the seat of a Greek archbishop, and has a theological seminary, a gymnasium, a school for young noblemen, and manufactories of cloth, linen, and iron ware.

RIB. See SKELETON.

RIBAUT, Jean, a French navigator, born in Dieppe, killed in Florida in 1565. When Admiral Coligni had obtained from Charles IX. a patent authorizing him to send an expedition to Florida, two vessels under command of Ribault sailed from Dieppe Feb. 18, 1562, and, leaving the usual track so as not to touch at any of the islands held by the Spaniards, came on April 30 in sight of the coast of Florida. Sailing northward along the coast, Ribault anchored in Port Royal harbor in the present state of South Carolina. A fort was built, probably not far south of the present site of Beaufort, and named Fort Charles in honor of the king of France, and 26 colonists were left to keep possession of the country. Returning home, Ribault found France distracted by a civil war, and no aid could be procured for the new colony, the members of which were soon reduced by violence and starvation, and at last the few survivors set sail for their native country in a crazy bark and were picked up by an English ship. A new expedition under René de Laudonnière sailed in April, 1564, and made a settlement on the river May, now called the St. John's, building a fort which they called Caroline. Affairs were mismanaged, no ground was cultivated, some engaged in depredations upon the Spaniards, and all were on the point

of returning to France when Ribault, who had sailed from Dieppe on May 22, 1565, arrived with a fleet of seven vessels, and superseded Laudonnière in the government of the colony. Scarcely had he anchored when, on Sept. 4, five Spanish vessels under Don Pedro Menendez de Aviles made their appearance. His name and objects were demanded. "I am Menendez of Spain," was the haughty answer, "sent with strict orders from my king to gibbet and behead all the Protestants in these regions. The Frenchman who is a Catholic I will spare; every heretic shall die." The French fleet, unprepared for battle, cut its cables; and the Spaniards after an ineffectual chase entered the harbor of St. Augustine. Against the advice of his officers, especially Laudonnière, Ribault determined to sail for St. Augustine with all the available forces of the colony, and there attack the Spaniards. He had scarcely reached the open sea when a terrible storm arose, by which his squadron was all wrecked on the coast of Florida not far from Cape Canaveral. In the mean time Menendez marched over land, surprised Fort Caroline, and massacred nearly 200 of both sexes. Ignorant of this, Ribault and more than 500 men set out for their fort, travelling through an unknown country. They divided into two parties, the first of which, consisting of 200 men, went in advance of the others, and after coming within a few leagues of St. Augustine surrendered to Menendez at discretion, and were executed. Ribault was with the second party, most of which also fell into the hands of Menendez, who massacred nearly all of them, among them their commander, "not as Frenchmen, but as Lutherans." The French and Spanish accounts differ in some particulars, but agree in the leading facts. In London a volume of 42 pages, now extremely rare, consisting of an English translation of the report of his first voyage made by Ribault to Coligni, was published under the title of "The whole and true Discoverie of Terra Florida (Englished the Florishing Land), conteyning as well the wonderful strange Natures and Maners of the People, with the merveylous Commodities and Treasures of the Country; as also the pleasant Portes and Havens, and Wayes thereunto never found out before the last year, 1562. Written in French, by Captain Ribault, the fyrst that whollye discovered the same, and now newly set forth in Englishe, the xxx. of May, 1563."

RIBBON (formerly spelled riband and riban; Fr. *ruban*), a narrow strip of woven silk, either plain or ornamented. The manufacture of ribbons first attained great importance in the 17th century. About 1680 embossed ribbons were much in fashion, as they are again becoming (1875). They are stamped with hot plates of steel, each piece having a portion of the pattern engraved upon it. Figured ribbons were made chiefly at Paris, but Lyons and Avignon were also largely engaged in the manufacture until after 1723, when the former had secured most

of the trade. Before the revocation of the edict of Nantes (1685) there were about 3,000 ribbon looms in Tours; but that measure, which banished the Protestants, broke up the industry. The city of St. Étienne, the chief town in the department of Loire, is now the principal seat of the ribbon manufacture in the world. The annual consumption of silk there is about 435,000 kilogrammes, and the manufactured product is worth about 65,000,000 francs. Four fifths of all the ribbons in France, and the finest and heaviest in the world, are made here, and about 28,000 workmen and 15,000 looms are employed. Basel in Switzerland is the second place in importance for the manufacture of ribbons, and a large portion of the medium grades imported to the United States come from here. Most of the Basel ribbons are plain or simply striped. In France and Switzerland all ribbons as well as dress silks are made on hand looms, which is the principal reason for the superiority in the French goods. It requires frequent manipulation in silk weaving to preserve a perfect evenness of tension and disposition of the threads, and all power-woven silk fabrics are disposed to "cockle" or crimp in places. Crefeld in Rhenish Prussia is another important place of manufacture, but nearly all its ribbons are black and plain. The ribbon industry is spread through the country, and is divided into small establishments, averaging from 20 to 50 looms each, and power is sometimes employed. In England ribbons are mostly made at Coventry, and with power looms. The warp of the best ribbons is made from the best organzine, thrown from the best Italian and French raw silk. For inferior sorts, silk from China, Japan, and Bengal is used, the last being the poorest. In the fancy ribbon called *chiné* the watered effect is produced by an irregularity in the surface caused by passing two ribbons laid together between two cylinders, one of which is heated.—Galloons, strong thick ribbons, the filling composed of cotton, are mostly made in England on power looms.

RIBBON FISH, the common name of several genera of acanthopterygian fishes of the family *tæniidae*. They are characterized by a compressed, elongated, ensiform body, with very small or no scales; the bones are of loose texture; the eyes large, and teeth small or none. To this ribbon-like body is attached a dorsal commencing close to or upon the head, and completely furnished with membrane; the caudal when present is distinct from the perpendicular fins, and in some is set on at a right angle, like a fan extended upward; the ventrals are often wanting, or are placed beneath the pectorals. They are all marine species.—Among the genera having a protractile mouth with a small aperture belongs *stylephorus* (Shaw), having neither teeth, scales, nor ventrals, and the caudal standing upward, its last ray continuous with the tail and produced into a filament longer than the body. In *trachypterus* (Gouan)

there are a few teeth, thoracic ventrals, a dorsal the whole length of the body, and an erect caudal; the northern ribbon fish or *vaagmeer* (*T. bogmarus*, Val.), from the polar seas, attains a length of 3 or 4 ft., sometimes much more; the skin is covered with a silvery envelope like the shining covering of the choroid of the fish's eye, consisting of minute needle-shaped crystals (see "Annals and Magazine of Natural History," vol. iii., London, 1849); it looks like a silvery ribbon in the water; the lateral line is armed with hooked scales. The *T. falx* (Cuv.) of the Mediterranean has 168 rays on the dorsal and plumes of rays on the head and tail; the color is brilliant silvery, with large, round, black spots.—In the genus *gymnetrus* (Bloch) the ventrals are reduced to a single ray, very long and dilated at the end; the caudal is very small and continuous with the dorsal. Of the eight species, the best known is the ribbon fish of the Mediterranean (*G. gladius*, Val.), attaining a length of 6 or 8 ft.; the rays of the dorsal over the head are elongated and curve backward like a crest; the silvery skin is studded with smooth osseous warts, and the fins are rosy red; like all the rest of the family, it is very easily broken; it lives in still deep waters, and is rarely seen except when thrown ashore after storms in a mutilated

Ribbon Fish (*Gymnetrus Hawkenii*).

condition. The *G. Hawkenii* (Bloch) is occasionally seen on the English coasts, and with its narrow, long, and shining body, and sinuous movements, has been the basis of more than one story of the sea serpent.—In the genera with non-protractile mouth, with large gape and ascending lower jaw, belongs *lophotes* (Giorna); this has on the head a vertical corneous crest sustaining a strong spine, which is the first dorsal ray; the dorsal extends the whole length of the body and has numerous simple rays, the anal and caudal small, and the ventrals near the pectorals. The *L. Cepedianus* (Giorna) of the Mediterranean attains a length of more than 4 ft., and is rarely seen. In *cepola* (Linn.) the body is covered with small scales; there is a single row of teeth in each jaw; the dorsal and anal are very long, and the caudal small. The red ribbon fish (*C. rubescens*, Linn.) occurs from the Mediterranean to the English coasts; it is about 18 in. long,

brilliant red, with indistinct dark bands, and the dorsal saffron yellow bordered with rose.

RIBBON WORMS, the common name of the family *nemertidae*, with the planarians constituting the order *turbellaria*. They are found on the seashore, are worm-like in shape, have a distinct anus, and, in many cases, no external opening to the water-vascular system. The larvæ are generally free-swimming and ciliated, a small portion only producing the adult, the rest being cast away. (See PLANARIANS.)

RIBERA, José. See SPAGNOLETTA.

RICARDO, David, an English political economist, born of Jewish parentage in London, April 19, 1772, died at Gatcomb park, Gloucestershire, Sept. 11, 1823. He received a commercial education in Holland, and was associated with his father in his business of stock broker. He became a Christian, and in 1793 married against his father's wishes. The partnership was dissolved, but the younger Ricardo in a few years realized a fortune. He studied mathematics, chemistry, and mineralogy, and was one of the promoters of the London geological society. In 1819 he was elected to parliament by the Irish borough of Portarlington, which he continued to represent till his death. His first publication was a tract, "The High Price of Bullion a Proof of the Depreciation of Bank Notes" (1809). His principal work is "On the Principles of Political Economy and Taxation" (1817). His works with an account of his life have been collected and edited by J. R. McCulloch (8vo, London, 1846). (See POLITICAL ECONOMY.)

RICAREES. See RICKAREES.

RICASOLI, Bettino, baron, an Italian statesman, born in Florence, March 9, 1809. He became known in 1847 as an advocate of constitutional liberty, and was chosen mayor of Florence. In 1848 he was elected to the Tuscan parliament. He opposed the extreme radicals, and after the disastrous battle of Novara (March 23, 1849) he favored the restoration of the grand duke of Tuscany as a barrier against Austrian invasion; but the reactionary policy of the latter soon drove him from political life. In 1859 he hastened the overthrow of the grand duke, and as a member of the provisional government he brought about the union of Tuscany with Sardinia, and became Victor Emanuel's chief representative and afterward governor general at Florence. On the death of Cavour in June, 1861, he succeeded him as prime minister, with several portfolios, holding the post till March, 1862; and he was again premier in 1866-'7. He was reelected to the Italian parliament in September, 1874, having first entered that body in 1861.

RICAUT, or Ryaute, Sir Paul, an English diplomatist, died in London, Dec. 16, 1700. He graduated at Cambridge, accompanied the earl of Winchelsea to Constantinople, was British consul at Smyrna for 11 years, accompanied the earl of Clarendon in 1685 to Ireland, and was for 10 years minister to the Hanse towns.

He wrote "The Present State of the Ottoman Empire" (1668); "The Present State of the Greek and Armenian Churches" (1679); and "History of the Turkish Empire from 1623 to 1679" (1680), a continuation of Knolle's "General History of the Turks."

RICCI, Federigo, an Italian composer, born in Naples about 1809. He studied with his elder brother Luigi (who died in 1859) at the conservatory of Naples, and jointly with him composed *Crispino e la comare*. He has been director of the operas at Madrid, Lisbon, and St. Petersburg.

RICCIO, Domenico. See BRUSASORCI.

RICCIOLI, Giovanni Battista, an Italian astronomer, born in Ferrara, April 17, 1598, died in Bologna, June 25, 1671. He was a member of the society of Jesus, taught in the Jesuit colleges of Parma and Bologna, and finally devoted himself to astronomy and geography. He undertook, though in a friendly spirit, to refute Copernicus in the *Almagestum Novum* (2 vols. fol., Bologna, 1651). His *Astronomia Reformata* (2 vols., 1665) is a completion of the former work. Mädler says that Riccioli's work "would have been forgotten had he not been led by vanity to find a place for his own name on the moon, an arrangement which he only achieved by displacing all the names used by Hevelius, at the risk of causing perplexity and confusion to later astronomers." He also published *Geographiæ et Hydrographiæ Reformatae Libri XII.* (fol., 1661) and *Chronologia Reformata* (1669).

RICE (Gr. *ὄρυζα*, Lat. *oryza*, Fr. *riz*), one of the cereal grains, *oryza sativa*, of the grass family. The genus is the type of a small tribe of *gramineæ*, the *oryzææ*, in which the one-flowered spikelets have the glumes very

Rice (*Oryza sativa*), bearded and beardless varieties. Separate Spikelet enlarged.

much reduced, or wanting altogether, and the palea, which in most grasses are more delicate, are in these firm and prominently nerved. In rice itself, an annual 2 to 4 ft. high, the lance-

linear leaves are rough on the upper surface; the flowers are in panicles with somewhat erect branches; the one-flowered spikelets have very minute glumes, not one fourth as long as the palea, which are much flattened laterally, the upper strongly three- and the lower five-nerved and pointed or bearing an awn; the palea grow with the grain, and completely invest it when ripe; stamens six. Rice has been cultivated from the earliest times in India, and the Chinese records state that it was introduced into that country in 2822 B. C.; it is found growing spontaneously in various parts of India, but chiefly on the banks of rivers, where it may have been carried from cultivation, and there is much doubt as to the place of its origin. In the wild state and in cultivation there are numerous varieties, differing in the size, shape, and color of the grain; in India a wild variety found on the borders of certain lakes is preferred by the rich Hindoos to all others, but as its yield is very small it is not cultivated. The improvement of rice by selection has long been practised by the Chinese; an early imperial edict enjoined the selection of the largest seed for sowing; the most valued kind cultivated in this country was obtained by a planter in South Carolina, who, noticing some remarkably long grains upon a head, selected these, and thus obtained the variety known as the long grain; in Ceylon 161 varieties are enumerated. Ordinary rice requires irrigation for its successful culture, but in the mountainous parts of India, in northern China, and in Japan, an upland variety (or species?) is in common cultivation, which is only 3 ft. high and is grown like ordinary grain. Rice is in some parts of India the chief article of produce, and in some districts, particularly in the marshy lands along the coast of Orissa, it is almost the only object of agricultural labor. In China and the islands of the eastern archipelago it is the principal support of the vast population of that portion of the globe. It is extensively cultivated in parts of Africa, in southern Europe, and in the tropical countries of North and South America. Various accounts are given of its introduction into this country. Gov. Alston of South Carolina in an agricultural address (1854) says: "Rice, for which we are indebted to the island of Madagascar, was introduced into Carolina and America at once, toward the close of the 17th century." One account states that a vessel from Madagascar "put into Carolina" and left some seed there. Gov. Alston gives no particulars, but says that a few grains of this Madagascar rice were sown in a garden, which is now one of the thickly built parts of Charleston, and that from this came the seed which has made South Carolina the great rice-growing state. Another account says that rice was grown in Virginia by Sir William Berkeley as early as 1647, but gives no particulars. There are three principal varieties in the rice-growing states: 1. White rice, valued for its earliness and for growing upon uplands; the husk

is cream-colored; an ounce contains 960 grains. 2. The gold-seeded, which has a deep yellow husk and a large, fine, white grain; an ounce contains 896 grains. 3. The long-grain, a sub-variety of the gold-seeded, obtained as already described; it has 840 grains in the ounce; the grains are longer than any other, and it is the most valued for exportation. For home use a long-awned variety called the white-bearded is often sown.—The best lands for the cultivation of rice are on the banks of rivers having a deep soil, chiefly of decomposed vegetable matters, and so situated as to be overflowed by the opening of tide gates. They must be above the salt or brackish water, and below the reach of the freshets, so as not to be flooded at unseasonable times. Other low lands not in the tide region may bear good crops if so situated that they can be drained and flooded at will. The land is prepared by a thorough system of embankments and ditches, so laid out as to form independent fields, the size of which is limited by the number of hands that can finish any one operation connected with the culture in one day; they usually consist of from 14 to 20 acres. The ditches are of various dimensions, often 5 ft. wide and as many deep, and sometimes the principal one is large enough to be used as a canal for transportation between the fields and the barns. Early in the winter the land is either ploughed or dug over with the hoe, and in the warm changes of the weather it is covered with water. In March it is kept dry, the drains are cleansed, the clods broken, and the surface smoothed off with the harrow or hoe, and trenches for the seed are made with a 4-inch trenching hoe at right angles with the drains 12 to 15 in. apart. In April and till the middle of May the seed is scattered in these trenches at the rate of $2\frac{1}{2}$ to 3 bushels to the acre. Great attention is given to selecting the seed; and sometimes the rice for this purpose is threshed by hand over a log or barrel, so as to throw out only the full-sized grains. "Volunteer" rice, the product of scattered seeds that have remained in the ground from the crop of the preceding year, is treated as a weed, and all that appears outside of the drills is cut up with the hoe. As the seed is sown it is covered lightly with soil, and the water is then let in through the gates and kept upon the land for four to six days, till the grain swells and begins to sprout. If the seed is not to be covered in the drills, it is previously prepared by stirring it in clayey water, and being then dried enough clay adheres to insure its remaining in the trenches when the water is let on. With the first method the water has to be let on a second time when the plants sprout and appear like needles above the ground, while with the latter one flooding answers. The water, after standing four to six days on the sprouts, is drained off, and when the plant is five or six weeks old the earth is stirred with the hoe; this is repeated ten days afterward, and the "long

water" is then put on for about two weeks, deep for four days, and then gradually diminishing. After the water has been drawn off about eight days and the field is dry, it is hoed to a good depth. On the appearance of a joint in the plant the land is lightly hoed again, and is then "laid by," that is, the "joint water" is put on to remain until the grain is matured, which may be two months. A few days before cutting, the water is run off and the ditches are washed out by the succeeding tide. The rice is cut with a sickle, and is carefully laid across the high and thick stubble to cure. The day after cutting, when the dew is off, it is bound in sheaves, and either borne on the heads of the laborers or packed in large flats, each one carrying the product of five to seven acres, to be conveyed to the barn yard. It is there stacked in small ricks, and when thoroughly cured it is put away in large stacks, each of which holds enough to make 200 to 400 bushels of threshed grain. The threshing is done with a machine invented by Calvin Emmons of New York, which is generally in use; this separates the grain by the action of toothed beaters revolving at the rate of 750 to 800 turns per minute. The grain comes from the threshing mills as rough rice or paddy, which requires milling or grinding to free it from the hulls; but it is often shipped in this state, in which it is well protected against damage, to be hulled in Europe or in New York, the rice being delivered fresh and clean to the consumers. The old method of removing the hulls was by pounding in hand mortars made of pitch pine blocks and holding about a bushel; it is at present hulled by steam power; an elevator takes the grain to the top of the building, where a screen frees it from sand; it then passes between a pair of heavy stones 5 ft. across, which remove the outer husk; thence it goes into large wooden mortars, the iron-shod pestles to which weigh 250 to 350 lbs. each, and is pounded for about two hours, when it is ready for screening. There are some mills which clean the rice by means of wire cards, without pounding. Finally the rice is passed through an inclined revolving cylindrical wire screen, the gratings of which grow coarser toward the lower end. It is thus assorted into a number of products. At the upper end of the screen the flour passes through, next the eyes and small pieces of broken rice, then the "middling rice," which consists of larger fragments and of the smaller grains, and lastly the "prime rice," or best and mostly unbroken grains. The head rice or largest grains of all, together with the rough that escaped the mill, pass out at the lower end and are thence returned to the mill. The prime rice as it falls through the screen descends to the "polishing" or "brushing screen," which is a vertical cylinder, laid up and down with shreds of sheepskin, and made to revolve rapidly within a wire screen. The rice, falling down in the space between these, is swept clean of the flour that adheres to it,

and is discharged below in a perfectly clean and polished condition. It is received in barrels holding about 6 cwt. each, and is then ready for the market. The middling and small rice, being cleaned by a fan, are kept for home consumption.—The average of several analyses gives as the proximate composition of rice: albuminoids 7.5, carbo-hydrates 76.5, water 14.6, ash 0.5. It will be seen that, as compared with wheat, rice is deficient in albuminoids, or flesh-forming principles; it is a very easily digestible food, and especially adapted to use in warm climates. New rice is said to produce indigestion and diarrhoea, and it should not be used until six months old. It is said that in some parts of India it is regarded as fit for food only when it has been kept three years. Some southern physicians assert that a diet consisting largely of rice produces near-sightedness, and that there are ten times as many persons with disordered eyes in the rice-consuming districts as elsewhere. The common method of cooking rice is to boil it in water properly salted, the rice being introduced into the water after this is boiling hot. In four or five minutes the water is drained off, and the pot covered is left 20 minutes longer on the coals. The rice is then ready to be served up as a vegetable, in which state the grains should be thoroughly cooked, but still retain their identity. In tropical countries it is much eaten in curries, which consist of rice, meat, and various aromatics. It is also made into puddings, as is the ground rice or rice flour, of which are made varieties of bread and of griddle cakes. Parched rice is one of the many substitutes for coffee. Rice flour or rice starch is found in the stores put up in packages as *rizena* and under other trade names. In medical practice a decoction known as rice water is often prescribed as a nutritive drink in fevers and inflammatory affections of the bowels, lungs, and kidneys. Its decoction fermented and distilled produces the spirituous liquor known as *arrack*. A useful cement is readily prepared from rice by mixing the flour with cold water and boiling. It dries nearly transparent, and is used in making many articles in paper. If made with little water, it may be moulded into models, busts, &c. Although so rich in starch, it has not been found an economical material for supplying that article.—The total production of rice in the United States in 1870, according to the federal census, was 73,635,021 lbs., of which South Carolina produced 32,304,825 lbs., Georgia 22,277,380, Louisiana 15,854,012, North Carolina 2,059,281, Florida 401,687, Mississippi 374,627, Alabama 222,945, Arkansas 73,021, Texas 63,844, and Tennessee 3,399. There has been a marked decrease in the production since the civil war; the total yield in 1850 was 215,313,497 lbs., and in 1860 187,167,032. A small quantity is annually exported from the United States, amounting during the year ending June 30, 1874, to 558,922 lbs., valued at \$27,075. The imports during

the same year amounted to 73,257,716 lbs., valued at \$2,083,248; 38,716,980 lbs. were imported from England, 29,218,123 from China, 2,443,601 from the British East Indies, and 1,087,785 from the Hawaiian Islands.

RICE. I. A S. E. county of Minnesota, drained by the head waters of Cannon river; area, about 575 sq. m.; pop. in 1870, 16,025. The surface is uneven; the soil is productive. It is intersected by the Milwaukee and St. Paul railroad. The chief productions in 1870 were 531,206 bushels of wheat, 227,931 of Indian corn, 348,543 of oats, 36,773 of barley, 57,862 of potatoes, 33,615 tons of hay, 20,607 lbs. of wool, and 364,260 of butter. There were 3,775 horses, 4,240 milch cows, 7,603 other cattle, 7,907 sheep, and 7,324 swine; 1 manufactory of agricultural implements, 3 of carriages and wagons, 6 of cooperage, 4 of furniture, 4 of saddlery and harness, 6 of tin, copper, and sheet-iron ware, 8 flour mills, 9 saw mills, and 1 distillery. Capital, Faribault. **II.** A central county of Kansas, intersected by the Arkansas river, and watered by Low creek and the Little Arkansas; area, 900 sq. m.; pop. in 1870, 5. It is traversed by the Atchison, Topeka, and Santa Fé railroad. The surface consists of undulating prairies, which have a fertile soil. The bottom lands are well timbered. Capital, Brookdale.

RICE, Indian, also called water rice, Minnesota rice, and water oats (*zizania aquatica*, the generic name being the ancient Greek one for some wild grain), an annual aquatic grass, with stems from 3 to 10 ft. high, growing in the swampy margins of streams, where it frequently forms the sole vegetation of extensive tracts. The genus belongs to the same tribe

ers, which have six stamens, and fall soon after shedding their pollen; the upper branches, with the pistillate flowers, are erect; the pedicels to the flowers club-shaped; glumes rudimentary; lower palet long-awned; the grain slender, cylindrical, about half an inch long, and purplish. The seeds of this plant afford abundant food for birds, especially water fowl; they are a favorite food of the reed bird, and when the grain is ripe the birds are shot in great numbers, especially along the Delaware river. The grain was formerly an important article of food with the Indians of the northwest, who collected their winter supplies by pushing their canoes through the thickets, and shaking off the grain, which falls when ripe with the slightest touch into the canoes. Every few years there has been an attempt to bring this plant into notice as a valuable cereal; but were there no other obstacle to its cultivation, the remarkable readiness with which the grain drops would prevent its coming into use. As a food the grain, according to Dr. Bachman, ranks with oats, an estimate which probably refers to the taste rather than to nutritious qualities. Recently the plant has been mentioned in English journals as a highly valuable paper stock, and some very coarse paper has been made from it; if the experiment should prove successful, the supply in our northwestern states and in Canada would be found practically inexhaustible.—Another species, *Z. miliacea*, is common southward; it differs from the foregoing in being a perennial, is somewhat smaller, and has the staminate and pistillate flowers intermixed, and not on separate branches of the panicle; the grain is ovate.

RICE, Luther, an American clergyman, born in Northborough, Mass., March 25, 1783, died in Edgefield district, S. C., Sept. 25, 1836. He graduated at Williams college in 1810, and after studying at Andover theological seminary sailed in 1812 for India as a missionary under the American board. On the voyage Mr. Rice, like his friend the Rev. Adoniram Judson, changed his views, accepting those of the Baptists. He consequently returned, and spent several years in organizing missionary societies and raising funds among that body. He also projected the establishment of the Columbian college at Washington, D. C., and was for many years its financial manager.

RICE BIRD, or Java Sparrow. See FINCH, vol. vii., p. 190.

RICE BUNTING. See BOBOLINK.

RICE PAPER TREE. Beautifully executed paintings of flowers and insects upon a delicate semi-transparent material, and the material itself, were brought from China in the early days of commerce with that country; for the want of a better name it was called rice paper, but the microscope showed that rice did not enter into its composition, and that it was some kind of pith. Various plants, among others the breadfruit, were suggested as the source of this material, but it was not until

Indian Rice (*Zizania aquatica*). Panicle, and a separate Pistillate and Staminate Flower.

with rice, but differs in having separated flowers, the staminate and pistillate being upon the same plant; the lower branches of the ample panicle are spreading, and bear staminate flow-

1852 that its history was made out; in that year Sir William Hooker in the "Journal of Botany" gave an account of the rice paper plant, which he referred to the genus *aralia*

Rice Paper Tree (*Fatsia papyrifera*).

and called *A. papyrifera*. In a revision of *aralia* and related plants Decaisne and Planchon in 1854, for botanical reasons, separated this from *aralia*, and made a new genus, *Fatsia*; and though the plant will be found in most current botanical and horticultural works as *aralia papyrifera*, its proper botanical name is *Fatsia papyrifera*. The tree is a native of Formosa, rarely growing more than 20 ft. high, and branching above; the young stems, leaves, and inflorescence are covered with a copious down of stellate hairs; the leaves, on long petioles, are often a foot across, round-heart-shaped, and five- to seven-lobed. The flowers are small and greenish, and are produced in pendulous panicles, 1 to 3 ft. long at the end of the branches. The plant has such ample leaves and so stately an aspect that it is a favorite in subtropical planting; a single young and vigorous specimen as a centre to a bed of low-growing plants produces a fine effect. It must be kept in a greenhouse or dry cellar during winter, though if left out the roots would no doubt prove hardy, as the writer had numerous young plants come up in the spring from fragments of the roots left in the soil on taking up a large plant the previous autumn. The vigorous stems have a pith which is an inch and a half in diameter and of a snowy whiteness; after the woody exterior is removed, the Chinese cut the pith into sheets, by paring with a sharp knife from the circumference toward the centre, unrolling it, as it were, and then flattening it out and pressing it under weights until dry, when it remains as a flat sheet. It is imported in sheets a few inches

square, and in dry weather it is exceedingly fragile. It is used solely for fancy ornamental work; some of the pith is exported in the stem for artificial flower makers, who find in its tissue a material which more closely than any other imitates the petals of the most delicate flowers.

RICH, a N. E. county of Utah, bordering on Idaho and Wyoming, and intersected by Bear river; area, about 850 sq. m.; pop. in 1870, 1,955. The E. part is mountainous. It is generally well timbered, and adapted to the raising of grain, stock, and vegetables. The chief productions in 1870 were 3,782 bushels of wheat, 6,175 of oats, 2,530 of barley, 4,660 of potatoes, and 775 tons of hay. The value of live stock was \$26,015. Capital, St. Charles.

RICH, **Claudius James**, an English traveller, born near Dijon, France, March 28, 1787, died in Shiraz, Persia, Oct. 5, 1821. When 15 years old he was familiar with Arabic, Hebrew, Syriac, Persian, and Turkish. In 1803 he became a cadet of the East India company, and in 1804 a writer at Bombay. He was appointed secretary to Mr. Lock, consul general to Egypt, and after perfectly acquiring the Turkish and Arabic languages, travelled over a great part of Palestine and Syria as a Mameluke, and finally reached Bassorah, whence he sailed to Bombay. In 1808 he was appointed by the East India company resident at Bagdad, where he remained about six years. In 1811 he visited the site of Babylon, and published a "Memoir on the Ruins of Babylon." After a second journey to that place, he published a "Second Memoir on Babylon" (1818). In 1820 he travelled in Kurdistan, going as far east as Sinna. His widow published his "Narrative of a Residence in Kurdistan" (1839). His collections are in the British museum.

RICH, **Edmund, Saint** (called by the French *Saint Edme*), archbishop of Canterbury, born in Abingdon, Berkshire, about 1190, died at Soissy, France, Nov. 16, 1242. He studied at Oxford, graduated in theology at the university of Paris, and lectured for some time there on Scripture. From 1219 to 1226 he taught philosophy at Oxford, being the first there to expound the logic of Aristotle. He accepted a prebend in the cathedral of Salisbury, but gave nearly all the revenues to the poor; and on April 2, 1234, he was consecrated archbishop of Canterbury. The king permitted him to enforce discipline in spite of the opposition of his clergy, his chapter, and even his own relatives. Pope Gregory IX. sent him a bull empowering him to appoint to all vacant benefices not filled within six months after the decease of the former occupant; but the king persuaded the pope to revoke the bull, and the pope then appointed Italians to the vacancies. Edmund, deeming this an abuse of the papal power, about 1239 retired to the Cistercian abbey of Pontigny in France. On account of enfeebled health he went to Soissy in Champagne, where he died. His remains were taken

back to Pontigny. He was canonized by Innocent IV. in 1246. (See PILGRIMAGE, and PONTIGNY.) Among his works are: "Constitutions" in 36 canons, extant in, among other collections, Labbe's editions of the councils; *Speculum Ecclesiæ*, published in vol. iii. of the *Bibliotheca Patrum*; and several manuscript treatises on moral subjects, preserved in the Bodleian library. A manuscript life of St. Edmund, by his brother Robert, is preserved in the Cottonian collection; another by Bertrand, his secretary and companion in exile and afterward prior of Pontigny, was published in Martenne's *Thesaurus Anecdotorum*.

RICHARD I., surnamed CŒUR DE LION (the lion-hearted), second king of England of the line of Plantagenet, born in Oxford, Sept. 13, 1157, died near Limoges, France, April 6, 1199. He was the second son of Henry II. and Eleanor of Aquitaine, and great-grandson in the female line of Henry I. He became celebrated for his proficiency in arms and his fondness for music and poetry. He engaged with his brothers Henry and Geoffrey in a revolt against Henry II. before he had completed his 16th year, and fled to France, where he was knighted by Louis VII. Claiming Aquitaine and Poitou, he was compelled to give way before his father, to whom he surrendered, and by whom he was forgiven. He was then known as the count of Poitou, but claimed to be duke of Aquitaine, and having distinguished himself in the war against the rebels there, the duchy was ceded to him by his father. The last rebellion in Aquitaine was aided by Richard's brother Henry, whose death brought it to an end, and made Richard heir apparent. The king then desired that Richard should give up Aquitaine to his brother John, which he refused to do, and by their father's orders John and Geoffrey ravaged his territories, which Richard punished by invading Brittany, of which Geoffrey was ruler. Richard subsequently surrendered Aquitaine to his mother, but it was shortly after restored to him, and by his father's orders he entered upon a successful war with the count of Toulouse. After a violent but brief rupture with his father, caused by his intimacy with Philip Augustus, Richard took the cross in the third crusade; but in spite of his vow he had to renew the war with the count of Toulouse. He also took part in the next contest between Henry and Philip; but a report prevailing that his father intended to exclude him from the succession, and confer the crown upon Prince John, Richard did homage to Philip for his English territories in France. In the war that followed, Philip and Richard were victorious, and dictated terms to Henry, who soon after died of mortification, July 6, 1189, cursing his sons. Richard was present at his burial, and was greatly affected. He was crowned at Westminster, Sept. 3. The people having risen against the Jews on the occasion of his coronation, he protected them. In the sum-

mer of 1190 the French and English armies destined for the crusade, under their respective kings, met on the plains of Vezelay, on the borders of Burgundy, 100,000 strong, and in September arrived in Sicily, where they passed the autumn and winter. This led to much trouble, Richard becoming involved in quarrels with the king of Sicily and his subjects, in which the French favored the latter. While they were at Messina a treaty was made which set Richard free from his betrothal to Philip's sister Alice, and enabled him to arrange for his marriage with Berengaria, daughter of Sancho, king of Navarre, who arrived in Sicily in company with his mother. Leaving Messina in April, 1191, his fleet encountered rough weather; some of his ships were wrecked on the coast of Cyprus, and their crews were inhospitably treated by the ruler of that island, Isaac Comnenus, who endeavored to get possession of the persons of Berengaria and of Richard's sister Joan, dowager queen of Sicily. Richard conquered the island in a fortnight, and made Isaac a perpetual prisoner. While at Cyprus he married Berengaria. On June 4 he sailed for Acre, capturing a Saracenic ship on his way. He found the French king at Acre, and that rivalry which defeated the object of the crusaders soon broke out, Philip favoring the faction of Conrad of Montferrat, while Richard supported Guy of Lusignan. Philip wished to assault Acre immediately, to which Richard objected, as all his troops had not arrived, and he was himself suffering from the pestilence that was raging in the Christian host. Philip made the attack, and was beaten. During his illness Richard is said to have received many courtesies from their enemy, Sultan Saladin. He slowly recovered, and the siege was prosecuted, every attempt of Saladin to relieve the place failing. Acre was surrendered on July 12, and soon afterward Philip sailed for France. On Aug. 20 Richard caused his Saracen prisoners to be butchered, because the terms of the surrender of Acre had not been fulfilled; and the next day he began his march toward Jerusalem, suffering much from the active operations of the light troops of Saladin. He completely defeated the Saracens at Arsuf Sept. 7, and took Jaffa; and after much opposition from his associates, he proceeded with a portion of the crusading force to Ascalon, which he reached in January, 1192, and where he was joined by most of the French troops. He rebuilt the walls, and hoped to invest Jerusalem; but the renewed dissensions of the Christians marred his plans. The news from England, too, required that he should return home. Still he adhered to the purpose of the crusade, and made arrangements to proceed to Jerusalem, but Saladin had so fortified that city that it was considered impregnable. Richard returned to Acre in July, and was about to embark for England, when he heard that Jaffa was in danger of falling into the hands of the Sara-

cens. Hastening to its relief, at the head of a small force, he defeated Saladin, and afterward defended the place against an attack by the Mohammedans. A truce soon followed, and Richard left Acre in October. He was shipwrecked at the head of the Adriatic, and while seeking to continue his journey by land became the prisoner of Leopold, duke of Austria, whom he had insulted and struck in Palestine. Surrendered by Leopold to the emperor Henry VI., he was held in confinement at various places, but was finally released for a ransom, notwithstanding the efforts of his brother John and the French king for his detention, and reached England March 13, 1194. The greater part of the latter years of his reign was passed in France, where he carried on almost constant warfare with Philip Augustus, in which he won brilliant successes, that do not seem to have produced any permanent effect. In 1199 he laid siege to the castle of Chalus, to compel the viscount of Limoges to surrender a treasure that had been found in one of his fields, which Richard claimed as sovereign lord of the soil. Here he received a wound from which, as it was unskillfully treated, he died. He left no legitimate children, and his wife Berengaria, who survived him many years, never visited England. Besides his reputation for soldierly valor and strength, he was renowned in his own day for wit, eloquence, and song, ranking as one of the best troubadours. Some of his poems in Romance have been preserved.

RICHARD II., eighth king of England of the house of Plantagenet, born in Bordeaux in 1366, supposed to have been murdered at Pontefract castle in February, 1400. He was the second and only surviving child of Edward the Black Prince, eldest son of Edward III., by Joan, sister of the last earl of Kent. The prince dying June 8, 1376, Richard became heir apparent, and succeeded to the crown, June 21, 1377. His coronation took place July 16. A council was appointed to conduct the business of government, from which the king's unpopular uncles were formally excluded, but its members were in part under their influence. The war between England and France was continued, to the disadvantage of England. Scotland was hostile; and the ambition of Richard's uncles, the duke of Lancaster (John of Gaunt) and the earl of Cambridge (afterward duke of York), who by right of their wives expected to obtain possession of Spain, was the cause of trouble between England and the peninsula. It was found necessary to lay new and heavy taxes, which were rigorously collected. The first poll tax, which bore upon persons in good circumstances, was submitted to; but when the tax was extended to persons of every condition, three groats being levied on each male and female above the age of 15 years, the returns were small. This was attributed to negligent collection, and a commission was

appointed to enforce the tax. Its proceedings were odious, and resistance was made in Essex and Kent. At Dartford, in Kent, one Walter the Tiler, having struck dead a tax gatherer who had insulted his daughter, was made chief of the insurgents, and hence the popular rising is known as Wat Tyler's rebellion. The insurrection spread over nine counties, and partook of the character of the Jacquerie that had occurred in France 23 years before. The insurgents marched upon London, and assembled to the number of 100,000 on Blackheath, June 12, 1381. The city was entered, the tower seized, and the archbishop of Canterbury, the treasurer, and several other persons of eminence, were put to death. There was some plundering, and the palace of the duke of Lancaster was destroyed. The early demands made upon the king were deemed reasonable, such as the abolition of slavery, the commutation of the dues of villenage, free trade in the market towns, &c.; and Richard promised that they should all be complied with, whereupon many of the people returned to their homes. Tyler now became insolent, and made further demands upon the king, compliance with which was impossible; and in an interview with Richard he behaved so arrogantly that he was slain by Sir William Walworth, lord mayor of London. The king, who was in his 16th year, immediately placed himself at the head of the rebels, thereby saving his own life and the lives of his attendants. They accepted him, and he led them into the country, and allowed them to depart without molestation. The promises made to the people were not kept, and they were punished with merciless severity. Richard married Anne of Bohemia, eldest daughter of Charles IV., emperor of Germany. An invasion of Scotland was made in 1385, the king heading a large army, which accomplished little. Lancaster being absent in Spain, the duke of Gloucester, another of the king's uncles, made himself master of the kingdom, but Richard was induced by his favorite, the earl of Oxford, to attempt to throw off the yoke. In the ensuing contest Gloucester triumphed, and was placed at the head of a council of regency in 1386, which held sovereign power. In 1387 the king, who was aided by the judges, sought to recover his power, but Gloucester defeated his soldiers, and slaughtered or banished his immediate supporters. Two years later Richard was more successful, and changed his ministers, Gloucester himself being removed. The French war languished, and that with Scotland was remarkable only for the battle of Otterburn, in which the Scotch were victorious. A truce for 25 years was concluded with France, and, Queen Anne having died in 1394, it was provided that Richard should marry Isabella, daughter of Charles VI., in 1396, though the princess was a mere child. Gloucester endeavored to recover his former power, but failed, the king being supported by parliament, and

crushing his enemies, some of the most prominent of whom were banished or put to death. Richard banished Henry of Bolingbroke, duke of Hereford, son of the duke of Lancaster, in 1398, for ten years; and on the death of Lancaster he made the term of banishment perpetual, and seized the estates of the exile. Richard had now become very unpopular, and in July, 1399, Henry, now duke of Lancaster, during the king's absence in Ireland, landed at Ravenspur, accompanied by a few eminent Englishmen. He was joined by several powerful nobles and great numbers of people of all degrees. Richard returned, but was seized and imprisoned, and deposed by parliament, after a renunciation of the crown had been obtained from him. Lancaster was called to the throne, and became king as Henry IV. Parliament thus set aside the legitimate heir to the throne, Roger Mortimer, earl of March (grandson of Lionel, duke of Clarence, third son of Edward III.), upon whom an earlier parliament had settled the crown, in accordance with the received laws of inheritance. Richard was imprisoned in Pontefract castle, and it is supposed that he was there murdered by his keeper, Sir Piers Exton. A corpse, purporting to be that of the ex-king, was exhibited in London for two days, and was buried in Westminster abbey; but the tomb having been accidentally opened long afterward, no marks of violence were found on the skull. One story was that he was starved to death. It has been plausibly maintained that he escaped from Pontefract and fled to the Western islands, was there recognized, and carried to the Scotch court, where he died in 1419, and was buried at Stirling. Richard was a weak prince, and owed his fall to his fondness for favorites, to the vehemence of his despotism in the latter part of his reign, and to the wantonness of his expenditures, which England was then ill able to bear. He was fond of literature, like most of the Plantagenets, and appreciated and enjoyed the works of Chaucer, Gower, and Froissart. In the 16th year of his reign (1393) the statute of *præmunire* was enacted.

RICHARD III., last king of England of the Plantagenet line, born at Fotheringay castle, Oct. 2, 1452, killed at the battle of Bosworth field, Aug. 22, 1485. He was the eleventh child and eighth son of Richard, duke of York, and of his wife Cecily Neville, daughter of the earl of Westmoreland. The duke of York was descended in the female line from Lionel, duke of Clarence, third son of Edward III., and the English throne was held by Henry VI., great-grandson of John of Gaunt, duke of Lancaster, Edward III.'s fourth son. York became the chief of that party which sought to set aside the line of Lancaster, but was defeated and captured at Wakefield at the close of 1460, and was immediately executed. His son Richard was a prisoner at the age of eight. On his father's death Richard was sent by his mother to Utrecht. When his eldest brother

became king of England, in 1461, as Edward IV., Richard was brought home and made duke of Gloucester, and afterward lord high admiral and chief constable of England for life, and chief justice of South Wales. In 1470, during the rebellion of the earl of Warwick and the duke of Clarence (the king's brother George), the duke of Gloucester was appointed commissioner of array in Gloucestershire, Devonshire, and Cornwall, and in the same year warden of the northern marches. In September he accompanied the king when he fled to Flanders because of the triumph of Warwick at the head of the Lancastrian party, and he was attainted and outlawed by parliament. When Edward returned Gloucester was in his train, and had the principal part in effecting that reconciliation between the king and Clarence which restored the throne to the house of York. At the battle of Barnet, April 14, 1471, Gloucester commanded the van of the Yorkist army, being in immediate opposition to Warwick, and by his conduct proved himself a skilful leader and a brave soldier, and contributed to the victory. The same post was assigned to him at the battle of Tewkesbury, 20 days later. In reward for his services, the king created him lord high chamberlain of England for life, and endowed him with a large number of manors and lordships that had belonged to the Nevilles, and several forfeited estates. He sought and found the lady Anne Neville, Warwick's youngest daughter, who had been betrothed to Prince Edward of Lancaster and concealed by her relatives, and married her about the month of March, 1472. He was a second time appointed lord high constable of England, and shortly afterward "keeper of all the king's forests beyond the Trent for life," and justiciary of North Wales, and took up his official residence at Pontefract castle, as chief seneschal of the duchy of Lancaster. Gloucester exerted his influence with the king to mitigate the horrors of the contests of those times, and especially in behalf of the Nevilles. In 1475 he accompanied Edward IV. in his invasion of France, and was the only Englishman of note in the army who was neither corrupted nor cajoled by Louis XI. On the execution of his brother Clarence, with which he had no connection, he received his possession of Barnard castle in Durham and his office of chamberlain; and he was constituted admiral of England, Ireland, and Aquitaine, and "one of the triers of petitions" in the parliament that met in 1478. War breaking out between England and Scotland, Gloucester was created lieutenant general of the kingdom, and in the summer of 1482 he took possession of Berwick, and penetrated to Edinburgh, at the head of a large army, and compelled the Scotch to accede to the terms of peace he proposed. One of the king's last acts was to bestow upon his brother the wardenship of the west marches of England, the lordship of Carlisle with everything

connected therewith, and a large sum of money. Edward IV. died April 9, 1483, and Richard, who was then in the north, prepared to go to London, and took the oath of allegiance to his nephew, Edward V., and compelled all who were under him also to take it. Hastening south, he seized the young king's person, and escorted him to the capital, having imprisoned Lords Rivers and Grey, and some other persons of the queen mother's party. Gloucester was appointed "protector and defender of the realm" by the council of state, which act parliament confirmed. He now resolved to make himself king, as the only alternative to becoming a victim of the queen mother's party. His proceedings are involved in much obscurity, but on June 13 Lord Hastings, the lord chamberlain, was suddenly seized at the tower by Gloucester's order and put to death, without even the form of a trial, on the charge of being concerned in a conspiracy against the protector and for the seizure of the government. Hastings, to whom Gloucester was attached, was probably murdered because the latter knew that he would never be false to Edward V. The children of Edward IV. were declared illegitimate, because their father had entered into a contract with Lady Elinor Butler before he married Elizabeth Grey. The young king was set aside by the estates of the realm, by whom Gloucester was requested to ascend the vacant throne. He complied, and became king June 26, 1483, with the style and title of Richard III. No opposition was made to him, and his coronation took place July 6. But the people soon began to murmur because of the fate of the young princes. (See EDWARD V.) The duke of Buckingham, who had been the chief agent in Richard's elevation to the throne, entered into a conspiracy for his overthrow. The earl of Richmond, who was regarded as the head of the Lancastrian party, was to be made king, on condition that he espoused Elizabeth, eldest daughter of Edward IV. This conspiracy failed, and Buckingham was executed. The queen dowager was prevailed upon to leave sanctuary, in which she had taken refuge, and to place herself and family in Richard's hands. The parliament of 1484 confirmed the king's title, and settled the crown on his son Edward, prince of Wales; but that prince died immediately after. Edward, earl of Warwick, son of the late duke of Clarence, was then named heir to the crown, but was soon set aside, and the earl of Lincoln, eldest son of the king's eldest living sister, the duchess of Suffolk, was substituted for him. Richard had now become very unpopular, because of the forced loans he had made, though his general legislation was good. The earl of Richmond, after several failures, resolved to make another attempt to gain the English crown. Assisted by the French government and by the duke of Brittany, he landed at Milford Haven Aug. 7, 1485. Richard had assembled a large army, and would have

easily crushed his rival but for the infidelity of some of his nobles. The two armies met on Bosworth field, Aug. 22, and Lord Stanley went over to Richmond in the heat of the battle, while the earl of Northumberland, who commanded the second line of the royal army, stood aloof. Even then the king might have retrieved his fortune but for the conduct of Sir William Stanley, who had remained neutral until Richard had hewn his way to where Richmond stood, when he joined the Lancastrians at the head of 3,000 men. This decided the result of the battle. Richard fell fighting bravely, declaring that he would die king of England. His body was basely treated by the victors, and was begged and buried by the nuns of Leicester in their chapel. Richard III. was the last of the Plantagenets, whose dynasty was succeeded by that of the Tudors.

RICHARD DE BURY. See AUNGERVILLE.

RICHARD PLANTAGENET, earl of Cornwall, a German emperor (known in English history as king of the Romans), born in Winchester in January, 1209, died April 2, 1272. He was the younger son of King John of England, was engaged in the French wars of his brother Henry III., and fought in Palestine. During the anarchy following the death of Conrad IV. his wealth secured him a partial election to the imperial throne (1256), while his opponents chose Alfonso of Castile. Richard was crowned at Aix-la-Chapelle in May, 1257, but achieved no general recognition. He took part in the troubles of England, and was made prisoner by Simon de Montfort at the battle of Lewes, May 13, 1264. He finally quitted Germany in 1269. The tin mines of Cornwall made him the richest prince in Christendom.

RICHARDS, Brinley. See supplement.

RICHARDS, Thomas A. See supplement.

RICHARDS, William T. See supplement.

RICHARDSON, the S. E. county of Nebraska, separated from Missouri on the east by the Missouri river, bordering S. on Kansas, and watered by the Nemaha and other streams; area, about 550 sq. m.; pop. in 1870, 9,780. It is traversed by the Atchison and Nebraska railroad. The surface is undulating and the soil very fertile. There are extensive prairies and numerous groves. The chief productions in 1870 were 140,143 bushels of wheat, 1,003,010 of Indian corn, 143,006 of oats, 98,056 of potatoes, 10,749 lbs. of wool, 164,358 of butter, and 15,398 tons of hay. There were 3,924 horses, 3,829 milch cows, 6,077 other cattle, 3,712 sheep, and 12,743 swine; 3 brick manufacturing and 3 saw mills. Capital, Falls City.

RICHARDSON, Benjamin Ward, an English physician, born at Somerby, Leicestershire, Oct. 31, 1828. He took his degree in 1854 at the university of St. Andrews, became a member of the royal college of physicians in 1856, and gained the Astley Cooper prize of £300 for his treatise on the coagulation of the blood, and the Fothergillian gold medal for his disquisition on the diseases of the foetus. He

was the first to employ ether spray for local pain (1866), and in 1867 he introduced methylene bichloride as a general anæsthetic. He has published "Discourses on Practical Physics," and many monographs in periodicals, and edited the "Journal of Public Health," founded by him, and the "Social Science Review."

RICHARDSON, Charles, an English philologist, born in July, 1775, died at Feltham, Middlesex, Oct. 6, 1865. In 1815 appeared his "Illustrations of English Philology," in which he advocated the principles set forth by Horne Tooke. He undertook the lexicographical portion of the "Encyclopædia Metropolitana," the first part appearing in January, 1818; but after the issue of the fourth part the work was suspended for some years. The publication of the dictionary as a separate work was commenced in January, 1835, and finished at the end of 1837 (2 vols. 4to). He also published a volume "On the Study of Languages" (12mo, 1854), an exposition of the principles laid down in the "Diversions of Parley."

RICHARDSON, James, an English traveller, born in Boston, Lincolnshire, Nov. 3, 1809, died at Ungurutua, central Africa, March 4, 1851. He early visited Algeria and the Barbary states, and in 1845 travelled across the desert of Sahara as far as Ghadames and Ghat, and after his return published "Travels in the Great Desert of Sak'ara" (2 vols., London, 1849). The English government placed him at the head of a new expedition, and, joined by Barth and Overweg, he left Tripoli in 1850, and was the first European visitor of the stony desert of Hammadah, whence he proceeded to Bornoo, where he died. Bayle St. John edited his "Narrative of a Mission to Central Africa" (2 vols., 1853).

RICHARDSON, Sir John, a Scottish naturalist, born in Dumfries, Nov. 5, 1787, died near Grasmere, June 5, 1865. He entered the navy in 1801 as an assistant surgeon, and subsequently became acting surgeon in the Hercules, 74. In 1819-'22 and 1825-'7 he accompanied Sir John Franklin in his arctic expeditions as surgeon and naturalist, and in the second with one detachment of the party explored the coast E. of the Mackenzie to the mouth of the Coppermine river. In 1848 he commanded one of the three expeditions which went out in search of Sir John Franklin, and returned in November, 1849. In 1855 he retired from the naval service. His most important work is the *Fauna Boreali-Americana* (4 vols. 4to, London, 1829-'37), in which he was assisted by Swainson and Kirby. He also published "The Arctic Searching Expedition, a Journal of a Boat Voyage through Rupert's Land and the Arctic Sea," &c. (2 vols. 8vo, 1851), and "The Polar Regions" (8vo, Edinburgh, 1861).

RICHARDSON, Samuel, an English author, born in Derbyshire in 1689, died in London, July 4, 1761. He was apprenticed to a printer of London, with whom he remained several years in the capacity of foreman. He then set up a

printing office for himself, and obtained the employment of printing the journals of the house of commons. In 1754 he was master of the stationers' company. To his avocation of printer he gradually united that of preparing indexes, prefaces, or dedications to the works which he printed; and finally, after he was 50 years old, he wrote his novel "Pamela" (2 vols. 8vo, 1741), five editions of which were published within a year. He afterward wrote two additional volumes, which are considered greatly inferior to the first. The ridicule of Fielding is well known. Richardson was deeply hurt by it, and predicted for Fielding a speedy fall into oblivion. In 1748-'9 appeared "The History of Clarissa Harlowe" (8 vols.), which, besides passing through several editions at home, was speedily translated into French and German. His last work of fiction was "The History of Sir Charles Grandison" (6 vols., 1753-'54). He also published "Æsop's Fables with Reflections," and "Familiar Letters to and from several Persons upon Business and other Subjects," out of which the project of "Pamela" had arisen. His "Correspondence" was published by Mrs. Barbauld in 1804 (6 vols. 12mo). A condensed edition of "Clarissa Harlowe" appeared in New York in 1874.

RICHELIEU, a S. W. county of Quebec, Canada, bounded N. W. by the St. Lawrence river; area, 189 sq. m.; pop. in 1871, 20,048, of whom 19,317 were of French origin or descent. It is intersected by the Richelieu river, and bounded S. E. by the Yamaska. Capital, Sorel.

RICHELIEU, Armand Jean Duplessis, cardinal and duke de, a French statesman, born in Paris, Sept. 5, 1585, died there, Dec. 4, 1642. He was first destined to the career of arms, and began his military education as marquis du Chillon; but his elder brother having resigned the bishopric of Luçon, he decided to take holy orders in order to succeed to that office. He studied theology, and was consecrated bishop on April 16, 1607. In 1614 he was one of the deputies of the clergy to the states general, and ingratiated himself with Maria de' Medici, assisted by Barbin, then comptroller of the treasury, and by Marshal d'Ancre. He was appointed almoner of the queen mother, and in November, 1616, he entered the council as secretary of state. When, after the murder of Marshal d'Ancre, Maria de' Medici was exiled to Blois, Richelieu accompanied her, actuated less by gratitude than by self-interest. His efforts to bring about a reconciliation between the king and his mother resulted only in his own banishment to his diocese of Luçon, which was followed in 1618 by a removal to Avignon, where he produced among other works one entitled *De la perfection du Chrétien*, a book of exalted asceticism. When Maria de' Medici was recalled to the court, she reinstated Richelieu in favor. From that period his credit constantly increased. Having strengthened his position by the marriage of his niece

with the nephew of the duke de Luynes, constable of France, he received the cardinal's hat (1622), reëntered the state council, and soon after, in spite of the unabated dislike of Louis XIII., rose to the premiership. His policy comprised three principal designs for the consolidation of the monarchy and the greatness of France: 1, the consummation of the work of Louis XI. by the extinction of the last remains of feudalism, and the full subjection of the high nobility to the royal power; 2, the subjugation of Protestantism in France, where it had assumed a character as much political as religious; 3, the abasement of the house of Austria, by crushing its ambition for universal domination, and consequently the elevation of the power of France abroad. As a preliminary step, he took from Austria the passes of the Valtellina, and secured them by treaty (1626) to Switzerland; and in the same year he set on foot the war against the Protestants and England, which extended to them her protection. Richelieu determined to strike at once a decisive blow, by taking from the Protestants their most important stronghold. The siege of La Rochelle was begun, and prosecuted with an activity to which the presence of the cardinal himself added a new impulse. The besieged made so desperate a resistance that the population of the city was reduced by war and famine from 30,000 to 5,000 souls, when they surrendered on Oct. 28, 1628. This event, followed by the treaty of Alais and the edict of Nîmes, put an end to the political power of Protestantism in France, and one of Richelieu's designs was accomplished. The other, against the high nobility, had already been attained by the imprisonment in the castle of Vincennes of the marshal d'Ornano, confidant and favorite of Gaston of Orleans, brother of the king. On hearing of that bold measure, the lords hastened to Fontainebleau, and there laid the first plot against the life of the cardinal, who, being informed of it, decided at once to make such an example as would strike terror into the hearts of his enemies. The count de Chalais of the house of Périgord, a giddy young man, led away far more by his love for the duchess de Chevreuse than by any political hatred, was arrested and imprisoned in the castle of Amboise. It is said that he was there seduced into disclosures against the queen by promises of mercy, but he was beheaded in 1626, his accomplices being either detained in prison or dispersed. But Richelieu meant to bring the nobility to practical obedience and submission to the royal power. In order to stop a bloody mania which threatened to deprive the country of the flower of its young noblemen, the penalty of death had been proclaimed against those who should fight duels. In defiance of the ordinance, in 1627 François de Montmorency, seigneur de Bouteville, and the count des Chapelles, young nobles of the highest rank, fought in Paris, in the Place Royale itself, and

both paid the penalty with their lives. The consolidation of the government at home did not divert the cardinal from carrying out his plans abroad. Charles de Gonzague, duke of Nevers, legitimate heir to the duchy of Mantua, without any help but the protection of France, was maintained in possession of his inheritance by force of arms. This war set at variance for the first time the cardinal and Maria de' Medici, who now joined Anne of Austria in opposition to the prime minister. The misunderstanding soon became a deep hatred. The queen mother determined to destroy her former favorite, and the cardinal was informed of his dismissal. There was great exultation at court, but Richelieu went to Versailles, where Louis XIII. had gone to hunt, and in a brief interview fairly frightened him into a reconciliation. This event is known under the name of *la journée des dupes*. Richelieu, more powerful than ever, took revenge at once upon his declared opponents. Marillac, who had been selected as his successor, was exiled to Lisieux, while his more important brother, the marshal de Marillac, was imprisoned and afterward put to death. Maria de' Medici did not yet consider herself defeated, and with the assistance of Gaston of Orleans laid new plots against the cardinal. This proved her ruin; she was exiled from France in 1631, while her partisans either shared her fate or were cast into prison, and for years she wandered about, pursued by the implacable resentment of Richelieu. In 1631, the year when Richelieu was elevated to the dukedom and peerage, her former associate the duke of Orleans and the marshal duke of Montmorency organized a new rebellion, but were overthrown at Castelnaudary, and Montmorency was executed. The thirty years' war was then raging in Germany. Richelieu did not hesitate to side with the Protestants against the house of Austria, and assisted Gustavus Adolphus by subsidies. The power of Richelieu had now attained its highest prosperity at home and abroad, both his domestic and foreign policy being crowned with success. While the power of Germany was assailed through the sword of the king of Sweden, the revolution was at the same time encouraged in England, whose court had been a refuge for Maria de' Medici. When Gustavus Adolphus fell at Lützen (1632), Richelieu contrived to secure to France new possessions on the left bank of the Rhine, and the services of the duke of Saxe-Weimar with his army. He now declared war against Spain, and was present at the capture of Perpignan (1642). At last Austria was humiliated, Portugal was separated from Spain (1640), French influence predominated in Catalonia, England was in full revolution, and France quiet and prosperous. Still, the administration of Richelieu was again threatened by intrigues at court or treason in the camps. An attempt, based upon a passion of Louis XIII. for Mlle. de Lafayette, had no result but the retirement of the intended mis-

tress to the convent of Chaillot, and the dismissal of the king's ordinary confessor. Nor was the rebellion of the count de Soissons, prince of the blood, any more successful, its leader being killed in his first battle against the royal troops at Sedan (1641). The last of these conspiracies of the nobility was the secret treaty of alliance concluded with Spain by the dukes of Bouillon and Orleans. The young marquis de Cinq-Mars, although indebted to Richelieu for the high favor and the high offices that he enjoyed at court, was one of the first among the conspirators. He was executed at Lyons, with his friend De Thou, Sept. 12, 1642. After this last vindication of his power, Richelieu, an invalid, returned to Paris in triumph, carried on a litter by his guards, escorted by an army, and surrounded by the utmost pomp. Two months after, his unrivalled fortune being at its very zenith, he died. Richelieu was the founder of the French academy. He also founded the *jardin du roi*, now the *jardin des plantes*, and enlarged the Sorbonne. He wrote two plays, *Mirame*, a comedy, and *La grande pastorale*, neither of any value. He is regarded as the author of *Mémoires du cardinal de Richelieu*, first published complete by Petitot in his collection of memoirs relating to French history (Paris, 1823); of the *Testament politique du cardinal de Richelieu* (2 vols., 1764); and of the *Journal du cardinal de Richelieu, qu'il a fait durant le grand orage de la cour* (2 vols., Amsterdam, 1649). The *Lettres, instructions diplomatiques*, &c., of Richelieu have been edited by Avenel (6 vols., Paris, 1853-'68). See also Martineau, *Le cardinal de Richelieu* (1865 *et seq.*).—The cardinal's elder brother, ALPHONSE LOUIS DUPLESSIS, who had resigned the bishopric of Luçon to retire to a Carthusian convent, was reluctantly compelled to resume high offices in the church. Archbishop of Aix in 1626, archbishop of Lyons in 1629, grand almoner of France in 1632, he died in 1653, 71 years of age. Richelieu had two sisters, of whom Françoise, the elder, married René de Vignerod, and had a son who died in 1646, leaving two sons, the elder of whom, LOUIS FRANÇOIS ARMAND DUPLESSIS, known as the marshal de Richelieu, born March 13, 1696, succeeded to the dukedom of his great-uncle, commanded in the seven years' war, was one of the most notorious rousés and worthless characters in French history, and died Aug. 8, 1788. His grandson, ARMAND EMMANUEL DUPLESSIS, duke de Richelieu, born in Paris, Sept. 25, 1766, was active as an agent of the French royal family during the revolution, entered the Russian civil service, was governor of Odessa, which he embellished, under Alexander I., refused to serve Napoleon, and was prime minister under Louis XVIII. He succeeded in procuring for the great European powers, at the congress of Aix-la-Chapelle (1818), terms much less severe than they had required from the French gov-

ernment in 1815. Though poor, he refused a national recompense from the chambers, and, when a pension of 50,000 francs was conferred on him, gave it to found a hospital at Bordeaux. He died March 16, 1822, and was succeeded in his titles by his sister's son, Armand François Odet de Chapelle de Jumilhac.

RICHER, Edouard, a French author, born in Noirmoutiers, department of Vendée, June 12, 1792, died in Nantes, Jan. 21, 1834. His father fell in battle with the Austrians in 1793. The national convention by a special decree adopted him, but from delicate health he did not follow his father's profession. He published in 1816 a poem entitled *Victor et Amélie*, and in 1821 a history of Brittany. He became a convert to the doctrines of Swedenborg, and wrote *La religion du bon sens, La clef du mystère*, &c. A collection of his Swedenborgian writings appeared at Nantes in 8 vols. (1832-'6), and his literary remains were edited in 1836, with a biography, by Émile Souvestre.

RICHERAND, Anthelme, baron, a French physiologist, born in Belley, Feb. 4, 1779, died in Paris, Jan. 25, 1840. He graduated at the Paris school of medicine in 1799, and at first devoted himself to the study of physiology. He was appointed surgeon to the hospital St. Louis, and in 1807 professor of surgical pathology in the faculty of medicine. When the allied troops occupied Paris on the fall of Napoleon, Richerand was distinguished by the vigor and devotion with which he cared for the sick and wounded of all nationalities, for which he received many honors from foreign governments, and the French government made him a baron and surgeon-in-chief to the three first legions of the national guard of Paris. His principal works are: *Nouveaux éléments de physiologie* (Paris, 1801), which passed through ten editions and was translated into many languages; *Leçons sur les maladies des os* (1805); *Nosographie et thérapeutique chirurgicales* (1805); *De l'enseignement actuel de la médecine et de la chirurgie* (1816); *Des officiers de santé et des jurys médicaux* (1834); and *De la population dans ses rapports avec la nature des gouvernements* (1837).

RICHLAND, the name of counties in six of the United States. **I.** A central county of South Carolina, bordered W. and S. W. by the Congaree river and E. by the Wateree, and drained by their branches; area, 465 sq. m.; pop. in 1870, 23,025, of whom 15,177 were colored. It has a somewhat hilly surface, with pine forests, and a fertile soil. Several railroads terminate at Columbia. The chief productions in 1870 were 121,495 bushels of Indian corn, 12,805 of sweet potatoes, 2,565 tons of hay, 5,453 bales of cotton, 26,823 lbs. of rice, and 1,082 of wool. There were 623 horses, 990 mules and asses, 1,367 milch cows, 2,623 other cattle, 1,063 sheep, and 5,579 swine; 1 manufactory of railroad cars, 3 of iron castings, 5 of machinery, 1 of cotton-seed oil, 7 flour mills, and 4 saw mills. Capital,

Columbia, which is also the capital of the state. **II.** A N. E. parish of Louisiana, drained by Bayou Beuf and other streams; area, about 550 sq. m.; pop. in 1870, 5,110, of whom 2,705 were colored. The surface is low and level and the soil highly productive. It is traversed by the North Louisiana and Texas railroad. The chief productions in 1870 were 95,225 bushels of Indian corn, 3,235 of peas and beans, 19,839 of sweet potatoes, and 6,051 bales of cotton. There were 958 horses, 653 mules and asses, 2,829 milch cows, 2,968 other cattle, 1,843 sheep, and 11,094 swine. Capital, Rayville. **III.** A N. county of Ohio, drained by the head waters of the Walhonding river; area, about 450 sq. m.; pop. in 1870, 32,516. It has an undulating surface and a fertile soil. Several railroads centre at the county seat. The chief productions in 1870 were 588,575 bushels of wheat, 621,881 of Indian corn, 700,830 of oats, 113,877 of potatoes, 36,740 tons of hay, 269,981 lbs. of wool, 833,005 of butter, and 58,543 of maple sugar. There were 8,580 horses, 8,979 milch cows, 10,091 other cattle, 71,093 sheep, and 25,116 swine; 5 manufactories of agricultural implements, 6 of brick, 24 of carriages and wagons, 12 of men's clothing, 12 of furniture, 3 of machinery, 4 of sash, doors, and blinds, 10 of tin, copper, and sheet-iron ware, 9 of woollen goods, 8 iron foundries, 14 tanneries, 3 breweries, 22 flour mills, and 11 saw mills. Capital, Mansfield. **IV.** A S. E. county of Illinois, drained by tributaries of the Wabash river; area, about 375 sq. m.; pop. in 1870, 12,803. It has a nearly level surface and a fertile soil. It is intersected by the Ohio and Mississippi railroad. The chief productions in 1870 were 150,268 bushels of wheat, 482,594 of Indian corn, 204,634 of oats, 11,422 tons of hay, 2,000 lbs. of tobacco, 31,612 of wool, 87,166 of butter, and 8,080 gallons of sorghum molasses. There were 3,254 horses, 2,723 milch cows, 4,054 other cattle, 12,447 sheep, and 12,256 swine; 3 manufactories of furniture, 2 of sash, doors, and blinds, 4 saw mills, and 2 flour mills. Capital, Olney. **V.** A S. W. county of Wisconsin, bordered S. by Wisconsin river and drained by Pine river and Knapp's and Mill creeks; area, 576 sq. m.; pop. in 1870, 15,731. It has a generally level surface and a fertile soil. The Chicago, Milwaukee, and St. Paul railroad skirts the S. border. The chief productions in 1870 were 189,900 bushels of wheat, 345,787 of Indian corn, 183,952 of oats, 108,926 of potatoes, 17,349 tons of hay, 9,126 lbs. of tobacco, 68,573 of wool, 316,734 of butter, 25,544 of cheese, and 350,436 of hops. There were 3,719 horses, 4,668 milch cows, 1,117 working oxen, 5,715 other cattle, 21,014 sheep, and 13,113 swine; 2 manufactories of furniture, 6 of carriages and wagons, 5 flour mills, and 8 saw mills. Capital, Richland Centre. **VI.** An E. county of Dakota, recently formed and not included in the census of 1870; area, about 1,400 sq. m. It is separated from Min-

nesota by Red river, and is watered by its affluents. The river bottoms are fertile; the rest of the county consists of rolling prairies.

RICHMOND, the name of counties in four of the United States. **I.** The southernmost county of New York, comprising Staten island, Shooter's island at the entrance of Newark bay, and the islands in Staten Island sound; area, 58½ sq. m.; pop. in 1870, 33,029. The chief productions in 1870 were 35,083 bushels of Indian corn, 12,001 of oats, 34,863 of potatoes, and 7,610 tons of hay. There were 2 bleaching and dyeing establishments, 4 manufactories of brick, 7 of carriages and wagons, 1 of machinery, 1 of linseed oil, 1 of lead and zinc, 5 of sash, doors, and blinds, 4 ship yards, 2 flour mills, and 5 distilleries. Capital, Richmond. (See STATEN ISLAND.) **II.** An E. county of Virginia, bordered S. W. by the Rappahannock river; area, about 175 sq. m.; pop. in 1870, 6,503, of whom 3,028 were colored. It has a nearly level surface and fertile soil. There are extensive forests of pine, and the waters abound with oysters. The chief productions in 1870 were 29,769 bushels of wheat, 121,680 of Indian corn, 9,781 of oats, 1,736 bales of cotton, and 1,913 lbs. of wool. There were 552 horses, 993 milch cows, 1,063 working oxen, 1,274 other cattle, 1,100 sheep, and 4,032 swine; 3 flour mills, and 2 saw mills. Capital, Warsaw. **III.** A S. county of North Carolina, bordering on South Carolina, and bounded N. E. by Lumber river and W. by the Yadkin; area, about 730 sq. m.; pop. in 1870, 12,882, of whom 6,598 were colored. The surface is undulating and the soil productive. It is traversed by the Carolina Central railroad. The chief productions in 1870 were 19,604 bushels of wheat, 131,855 of Indian corn, 21,350 of oats, 11,970 of peas and beans, 43,364 of sweet potatoes, and 5,130 bales of cotton. There were 871 horses, 768 mules and asses, 2,346 milch cows, 3,295 other cattle, 2,247 sheep, and 19,088 swine. Capital, Rockingham. **IV.** An E. county of Georgia, separated from South Carolina by the Savannah river; area, about 350 sq. m.; pop. in 1870, 25,724, of whom 12,565 were colored. It has an uneven surface, and the soil is fertile near the streams. It is intersected by several railroads terminating in Augusta. The chief productions in 1870 were 3,610 bushels of wheat, 77,895 of Indian corn, 18,544 of sweet potatoes, 4,286 lbs. of rice, and 2,017 bales of cotton. There were 342 horses, 507 mules and asses, 739 milch cows, 1,334 other cattle, 378 sheep, and 3,718 swine; 2 manufactories of cotton goods, 4 of iron castings, 8 of machinery, 2 of marble and stone work, 2 of saddlery and harness, 1 of woollen goods, 5 flour mills, and 5 saw mills. Capital, Augusta.

RICHMOND. **I.** A S. county of Quebec, Canada, drained by the St. Francis river, an affluent of the St. Lawrence; area, 525 sq. m.; pop. in 1871, 11,213, of whom 3,718 were of French, 2,935 of English, 2,463 of Irish, and

1,872 of Scotch origin or descent. It is traversed by the Grand Trunk railway. Capital, Richmond East. **II.** A county of Nova Scotia, Canada, occupying the S. portion of Cape Breton island, with Madame and smaller islands adjacent; area, 623 sq. m.; pop. in 1871, 14,268, of whom 6,965 were of French, 4,902 of Scotch, 1,437 of Irish, and 746 of English origin or descent. Capital, Arichat, on Madame island.

RICHMOND, a city, port of entry, and the capital of Virginia and of Henrico co., the largest city in the state, on the N. bank of James river, here crossed by five bridges, at the head of tide water, and at the lower falls, about 150 m. from its mouth, and 95 m. S. S. W. of Washington; lat. $37^{\circ} 32' 17''$ N., lon. $77^{\circ} 27' 28''$ W.; pop. in 1790, 3,761; in 1800, 5,737; in 1810, 9,785; in 1820, 12,067; in 1830, 16,060; in 1840, 20,153; in 1850, 27,570; in 1860, 37,910; in 1870, 51,038, of whom 3,778 were foreigners and 23,110 colored; in 1874, 60,705. The city is built on Richmond and Shockoe hills, which are separated by Shockoe creek, and is surrounded by beautiful scenery. It is regularly laid out and well built; the streets, which are lighted with gas, cross each other at right angles. There is a line of horse cars. On Shockoe hill are the state capitol and other public buildings. The capitol, in the centre of a park of eight acres, is a large and imposing edifice, having at one end a handsome portico; it contains in its central hall Houdon's celebrated statue of Washington, and near by a marble bust of Lafayette. On the east of the capitol square is the governor's mansion. On the esplanade leading from the mansion toward the W. gate of the square stands a monument by Crawford, consisting of a bronze equestrian statue of Washington rising from a pedestal of granite surrounded by bronze figures of Patrick Henry, Thomas Jefferson, John Marshall, George Mason, Thomas Nelson, and Andrew Lewis. The square also contains a marble statue of Henry Clay. Among the principal public buildings, in different parts of the city, are the state penitentiary, state armory, court house, jail, custom house (also occupied by the post office), theatre, and two markets. There are several cemeteries, the handsomest of which is Hollywood. The falls of James river afford im-

mense water power. Vessels drawing 16 ft. can ascend to within a mile of the centre of the city, at a place called Rockets, and those of 18 ft. draught to Warwick, 3 m. below. A canal has been built around the falls, and above them there is navigation for over 200 m. Improvements are in progress in the river, which are expected to render the docks accessible by vessels drawing 19 ft. The James River and Kanawha canal extends to Buchanan, 196½ m. Richmond is the point of intersection of five lines of railroad, viz.: Chesapeake and Ohio; Richmond, Danville, and Piedmont; Richmond, Fredericksburg, and Potomac; Richmond and Petersburg; and Richmond, York River, and Chesapeake. The value of its foreign commerce for the year ending June 30, 1874, was as follows: imports, \$156,260; exports, \$3,463,626. The number of entrances was 33, tonnage 9,032; clearances 74, tonnage 36,305; number of vessels belonging in the district, 31,

State Capitol of Virginia.

tonnage 2,528. The chief articles of export are tobacco and flour. The latter is noted for its excellent quality, and is mostly shipped to Brazil. Great quantities of tobacco are shipped to the north. The number of entrances in the coastwise trade for the year ending Sept. 30, 1873, was 719, tonnage 512,613; clearances, 579, tonnage 487,004. Regular lines of steamers run to Norfolk, Baltimore, Philadelphia, and New York. The manufactures give employment to more than 4,000 men. The principal establishments are 13 iron works, machine shops, and foundries, producing all kinds of wrought- and cast-iron work, steam engines, agricultural implements, tobacco machinery, &c.; one sugar refinery, one tannery, four manufactories of plug and smoking tobacco, four of cigars, three of coaches and wagons, one each of saws, files, &c., of sash, doors, and blinds, of sheetings and shirtings, of stoneware, sumach, cedar ware, bedding and

corn husks, furniture, and paper boxes; a type foundry, a stone-cutting establishment, and five flouring mills, capable of producing 2,000,000 barrels annually. The Tredegar company has a capital of \$1,000,000 and employs 1,200 hands, producing spikes, axles, bar iron, freight cars, &c., to the annual value of \$3,250,000. There are several granite quarries in the vicinity. The city contains four national banks, with an aggregate capital of \$1,400,000, six state banks and savings institutions, with \$1,000,000 capital, and ten insurance companies. It is divided into six wards, and is governed by a mayor and council. The police force on Feb. 1, 1875, consisted of 82 men. The fire department comprises five steam engine companies, two hook and ladder companies, and one hose company, with a total of 100 men, and has a telegraphic alarm. The city is supplied with water from two reservoirs, with an aggregate capacity of 50,000,000, gallons, which are filled from the river by force pumps. The assessed value of real estate in 1874 was \$41,600,000. The receipts during the year ending Feb. 1, 1875, amounted to \$1,574,355 37, including \$68,670 84 on hand at the beginning of the period; disbursements, \$1,495,717 56; balance, \$78,637 81. The bonded debt on Feb. 1, 1875, amounted to \$4,239,727 97; floating debt, \$32,379 18; total, \$4,322,107 15. The whole number of persons admitted to the city almshouse during the year ending on that date was 812; average number of inmates, 245. One of the state insane asylums is situated here. There are several orphan asylums and other charitable institutions. The public schools are under the charge of a board of nine members, besides the mayor, who is president *ex officio*. There are seven school houses for white children, with an aggregate seating capacity of 3,093, and five for colored children, with a seating capacity of 1,758. The number of schools in operation during the year ending June 30, 1874, was 92, of which 59 (1 high, 21 grammar, and 37 primary) were white, and 33 (5 grammar and 28 primary) were colored; whole number of teachers, 105, of whom 10 were colored; pupils enrolled, 4,959 (3,041 white and 1,918 colored); average daily attendance, 3,595 (2,228 white and 1,367 colored). The expenditure for school purposes during the year ending Aug. 1, 1874, amounted to \$80,932 52, of which \$50,542 90 were for teachers' wages and \$19,108 26 for construction and furniture; value of school property on the above date, \$207,537 75. There are numerous private schools. Richmond college, under the control of the Baptists, founded in 1840, has a library of 6,000 volumes and a law department organized in 1868. The Richmond institute (Baptist), for theological instruction, was founded in 1868; it has a library of 1,200 volumes. The medical college of Virginia was established in 1851. Seven daily (two German), four semi-weekly, and ten weekly newspapers, and two semi-monthly and seven monthly periodicals are published. There

are 49 churches, viz.: 15 Baptist (7 colored), 1 Disciples', 6 Episcopal, 1 Friends', 4 Jewish, 3 Lutheran, 11 Methodist (1 colored), 4 Presbyterian, 3 Roman Catholic, and 1 Unitarian. —Richmond was founded by William Byrd in 1737. It was incorporated in 1742, and became the state capital in 1779, at which period it was a small village. On the night of Dec. 26, 1811, the theatre took fire while crowded with spectators, of whom upward of 70 perished, among them the governor of the state. A church, known as the "Monumental" church, has been erected on the site. In May, 1861, Richmond was made the seat of government of the "Confederate States of America," and it so continued until their overthrow in April, 1865. Although geographically near the N. E. frontier, it was practically the military centre of the confederacy. If the railroads meeting here, and extending to every part of the south and southwest, had been planned for military purposes, they could not have been better placed. The defensive position of the city is excellent. On two sides it is covered by the James; on the other sides the Chickahominy and swamps form a natural line of exterior defence. Here also were mills, manufactories, and foundries. When McClellan landed on the peninsula in the spring of 1862, the immediate capture of Richmond was apprehended; and even while he was held in check at Yorktown a panic arose. On April 21 the confederate congress hastily adjourned; the government archives were packed up, and the railroads were crowded with fugitives. The panic increased when Yorktown was abandoned, Norfolk seized, and the Merrimack destroyed. But the state legislature resolved that the city should be defended to the last extremity; the governor ordered that all business except the filling of government contracts should be suspended at 2 o'clock; the militia was to assemble at 3 and drill till sunset. At this time there were no fortifications, and no attempt was made to obstruct the passage of the Chickahominy; and a determined attack at any time during the campaign would have had good chances of success. From August, 1862, to June, 1864, while the war was carried on in northern Virginia, Maryland, and Pennsylvania, Richmond was held only by a few thousand militia; and several expeditions, mostly of cavalry, were undertaken rather with the design of liberating the Union prisoners and destroying the public works than of permanently holding the city, which might have been easily retaken by the confederates, who were in force between it and the Union army of the Potomac. In March, 1864, Kilpatrick, with 4,000 cavalry, came on the north within 4 m. of the city, penetrating two lines of defences, but was stopped at the third, and abandoned the enterprise. At the same time Dahlgren with a few hundreds reached the inner line from the south, but was repulsed, himself killed in the retreat, and his command dis-

persed. Meantime the defences of Richmond had been made too strong to be assailed in front, and the operations of Grant, although really directed against that city, took the form of the siege of Petersburg. (See PETERSBURG, SIEGE OF.) Although several strong demonstrations were made against Richmond during the siege, the exterior lines were never carried, the interior lines were never even seen, and in the city itself there was nothing to show that it was beleaguered. The only garrison was the militia of the city, under Ewell, and little was known of what was passing in the army. When, on the morning of April 2, 1865, Gen. Lee informed Jefferson Davis that the army would abandon Petersburg and Richmond that night, there was a universal panic. The government archives were hastily packed up and taken to the station of the Danville railroad, by which the president and cabinet set off in a special train, and every possible effort was made by the people to escape. As night fell the disorder rose to tumult, riot, and general pillage. Toward midnight the last of the troops had crossed the James, and Ewell, who commanded the rear guard, ordered the bridges to be burned, the ironclads in the river blown up, and everything destroyed which could be of use to the enemy. In the very heart of the city were four great government warehouses filled with tobacco, which, in spite of the remonstrances of the mayor, Ewell ordered to be set on fire. Close by were the Gallego flour mills, said to be the largest in the world, and the arsenals filled with loaded shells. The flames spread from street to street, covering acres of the business part of the city, and the tumult and pillage continued all night. Early the next morning the federal general Weitzel entered the city with 20 horsemen, finding before the abatis in his front a line of torpedoes, still marked by flags, followed by three lines of works, each of the inner ones commanding that exterior to it. The whole Union army soon marched in. Gen. Shepley, who had filled the same post at New Orleans, was made military governor. The conflagration was still spreading, and every effort to suppress it was unavailing till toward evening, when the wind veered, and the flames died out. Fully one third of Richmond had been burned, comprising nearly all its business portion.

RICHMOND, a city and the county seat of Wayne co., Indiana, on the E. side of the east branch of Whitewater river, 68 m. E. of Indianapolis; pop. in 1850, 1,443; in 1860, 6,603; in 1870, 9,445; in 1875, 11,579, of whom 1,581 were Germans and 422 Irish. It is built on rolling ground 700 ft. above tide water, and is surrounded by a fertile agricultural district, with which it has an important trade. There is a good fire department. Horse cars traverse the principal streets. In the N. E. corner of the city are fair grounds 33 acres in extent. Richmond is an important railroad centre, the

Little Miami, the Cincinnati, Richmond, and Fort Wayne, and the Cincinnati, Eaton, and Richmond railroads, as well as several divisions of the Pittsburgh, Cincinnati, and St. Louis railroad, centring here. There is good water power. The number of manufacturing establishments in 1874 was 127; number of hands employed, 1,507; capital invested, \$1,807,785; value of raw materials used, \$795,784; of products, \$2,729,346. The chief articles of manufacture are threshing machines, portable engines, ploughs, flour and saw mill works, school and church furniture, and burial caskets of wood. The slaughtering of hogs is extensively carried on, the number slaughtered in 1874 being 27,700. There are three banks, with an aggregate capital of \$900,000. The taxable value of property in 1875 was \$8,383,767. The principal charitable institutions are the orphans' home and the home for friendless women. There are nine public school houses, with a high school and inferior grades, having 37 teachers and an enrollment of 1,900 pupils. There are also two Lutheran and two Roman Catholic schools and a business college. The Friends' academy is an important institution. Earlham college, also under the auspices of the Friends, was founded in 1859. It has preparatory and collegiate departments, and admits both sexes. In 1874-'5 it had 14 instructors, 221 students, and a library of 3,500 volumes. The buildings are about half a mile W. of the city. Richmond has two theatres, two daily and six weekly (two German) newspapers, a public library of 10,000 volumes, and 20 churches: 2 Baptist, 1 Christian, 1 Episcopal, 1 Evangelical Association, 3 Friends', 2 Lutheran, 4 Methodist, 1 New Jerusalem, 2 Presbyterian, 2 Roman Catholic, and 1 Wesleyan.

RICHMOND, a town of Surrey, England, 10 m. W. S. W. of St. Paul's, London; pop. in 1871, 15,113. It is built on the side and summit of an eminence on the Thames, and is famous for its scenery. It is well paved, lighted with gas, accessible by rail and steamboats hourly from the capital, and connected by bridge with Twickenham. It has a theatre, lecture hall, and numerous places of worship; and near by are Pembroke lodge, the seat of Earl Russell, within the park, and many other splendid residences. The Wesleyan theological seminary, on the hill, is a fine specimen of the Tudor style. The parish church contains monuments to Thomson, Edmund Kean, Dr. John Moore, Gilbert Wakefield, and other noted men who are buried here. The Star and Garter hotel, near the park, is celebrated alike for its diners and for the unrivalled prospect it commands. Originally built in 1738, it has been repeatedly enlarged, was partially destroyed by fire in 1870, and was rebuilt in 1872. Here the annual dinners of the bank of England directors and of many of the great commercial companies of London are given.—Richmond was originally called Schene or Scheen, afterward Sheen, and was a royal residence under

Edward I. and II. Edward III. died here in 1377. Chaucer was surveyor of the works of the palace in 1389. Anne, queen of Richard II., died here in 1394. In 1414 Henry V. founded a Carthusian priory, which was appropriated by Henry VIII. in 1540, restored by Mary in 1557, and suppressed by Elizabeth in 1559. The palace was burned down in 1498, but was rebuilt immediately after by Henry VII., who changed the name of Sheen to Richmond, from his title of earl of Richmond in Yorkshire before his coronation, and he died here in 1509. Mary temporarily imprisoned here Elizabeth, who afterward made it her favorite residence, and died here in 1603. Richmond park, originally New park, comprising 2,253 acres, surrounded by a brick wall 8 m. in circumference, was enclosed by Charles I. about 1636, and was thrown open to the public in 1752. The palace was partially destroyed under the commonwealth, and was pulled down in the next century. George III. joined the old palace park to Kew gardens. Sir W. Chambers built the Richmond observatory in 1769.

RICHMOND, Countess of. See BEAUFORT, MARGARET.

RICHMOND, Legh, an English clergyman, born in Liverpool, Jan. 29, 1772, died at Turvey, Bedfordshire, May 8, 1827. He graduated at Trinity college, Cambridge, in 1794, was ordained in 1797, became a curate in the Isle of Wight, and in 1805 chaplain of the Lock hospital, London, and in the same year was presented to the rectory of Turvey. He wrote "Annals of the Poor," including the celebrated story of the "Dairyman's Daughter," of which separately more than 4,000,000 copies in 19 different languages have been circulated. He also published "The Fathers of the English Church, or a Selection from the Writings of the Reformers and Early Protestant Divines of the Church of England" (8 vols. 8vo, 1807-'11), and "Domestic Portraitsures," consisting of memoirs of his three children.

RICHTER, Johann Paul Friedrich, popularly known as **JEAN PAUL**, a German author, born at Wunsiedel, near Baireuth, March 21, 1763, died in Baireuth, Nov. 14, 1825. He studied in the gymnasium at Hof and in the university of Leipsic, and published his first work in 1783-'4. Poverty drove him from Leipsic, and during ten years he taught in private families. Subsequently he resided at Hof until his mother's death in 1797, when he returned to Leipsic, and in 1798 joined Herder at Weimar. In 1801 he married Karoline Mayer in Berlin, and removed to Meiningen, and next to Coburg, and in 1804 to Baireuth, where he spent the rest of his life in the enjoyment of a pension of 1,000 florins. The death in 1820 of his only son gave a blow to his health from which he never recovered. His writings abound in a bewildering variety of playful, witty, pathetic, childlike, and sublime thoughts, and are pervaded by a high moral tone; but his style is so incongruous and intri-

cate that Reinhold published in 1810 a special work to unravel his meaning. His principal works are: *Die unsichtbare Loge*, a novel (2 vols., Berlin, 1793); *Hesperus* (4 vols., 1794; translated into English by Charles T. Brooks, Boston, 1865); *Blumen-, Frucht- und Dornenstücke* (4 vols., 1796-'97; translated into English by E. H. Noel, with a memoir of the author by Carlyle, 2 vols., Boston, 1863); *Das Kampanerthal* (Erfurt, 1797; English translation, "The Campaner Thal and other Writings," Boston, 1863); *Titan* (Berlin, 1800-1803; translated by C. T. Brooks, 2 vols. 12mo, Boston, 1862); *Fliegeljahre* (4 vols., Tübingen, 1804-'5); *Vorschule der Aesthetik* (3 vols., Hamburg, 1804); and *Levana, oder Erziehungslehre* (Brunswick, 1807; 4th ed., enlarged from his posthumous papers, Stuttgart, 1861; English translation, Boston, 1863). The last two express his views on philosophy, in which he sympathized with Herder and Jacobi, and opposed Fichte. His complete works comprise 65 vols. (Berlin, 1826-'38). E. Förster and Christian Otto published *Wahrheit aus Jean Paul's Leben*, partly founded upon his autobiography (8 vols., Breslau, 1826-'33). Förster was the sole author of *Denkwürdigkeiten aus Jean Paul's Leben* (7 vols., Munich, 1863). Among the published correspondence of Jean Paul are his *Briefe an eine Jugendfreundinn* (Brandenburg, 1858). Carlyle was the first in 1827 to familiarize the English with Jean Paul's genius. In the United States appeared a biographical sketch after the German, and extracts from *Fliegeljahre*, translated by Eliza Buckminster Lee (Boston, 1842; new ed., 1864).

RICINUS. See CASTOR OIL.

RICKAREES, or **Ricarees**, called also Aricaras, Rees, and Black Pawnees, a tribe of Indians of the Pawnee family, living on the Upper Missouri. They are said to call themselves Starrahé and also Panani. They are an offshoot of the Pawnees of Platte valley, Nebraska, from whom they separated about a century ago. They were originally ten large tribes, but were reduced by smallpox in 1791 and by the hostility and oppression of the Teton and other Sioux. They were warlike, the men generally going naked, their heads adorned with feathers. They came into collision with the whites before 1810. Twelve years after they were near Cannon Ball river, in two palisaded villages of 141 lodges. On June 2, 1823, they attacked Gen. Ashley's party of traders, killing and wounding 23. Col. Leavenworth was sent against them, and defeated them in a severe battle, Aug. 9. They made peace, but fled during the night of the 13th, and their towns were fired by the traders. The Rickarees went to the Platte, and as the Sioux seized their country became wanderers. By 1825 they were again on the Missouri, where a treaty was made with them, July 11. As they still remained hostile, all trade with them was closed in 1831, when they again became wanderers. Some years later they returned from

the Platte and united with the remnants of the Mandans, and have since lived with them and the Minnetarees, engaging largely in agriculture. In 1862 they removed to Fort Berthold. During the civil war a number served as scouts in the army. By the treaty of July 27, 1866, \$75,000 a year is to be expended for the three tribes; and by executive order of April 12, 1870, a reservation of 8,640,000 acres in N. W. Dakota and E. Montana was assigned to them. They have begun to erect log huts instead of earth lodges, and have been assigned to the care of the American board of foreign missions, but up to 1875 had no missionary or school. They were reported in 1874 at 975, though Dr. Matthews estimates them at only 800.

RICKETS (Lat. *rachitis*, from Gr. *ῥαχίς*, the back bone), a disease of children characterized by an arrest of ossification, and leading to deformity, chiefly of the lower limbs. Rickets rarely occurs before the child is 12 months old, and commonly first shows itself in the second year. It is most frequent among those who inherit unhealthy constitutions, and who are ill fed or confined to a damp and badly ventilated atmosphere. According to Trouseau, 90 out of every 100 children affected with rickets have been either brought up entirely by hand or have been prematurely weaned. Very frequently the disease supervenes on some exhausting and long continued illness. Trouseau thinks the tardy evolution of the first teeth is indicative of a tendency to rickets. The first symptom of the complaint is an enlargement of the joints, the wrists, knees, &c. Afterward the long bones, particularly those of the lower extremities, give way under the weight of the body, and become bent, sometimes in one, sometimes in another direction; often the ribs are pressed in and the sternum pushed outward, making the child what is termed chicken-breasted; the bones of the pelvis and those of the spine become variously bent and deformed. This is due to a deficiency in the proportion of calcareous matter in the bones, which renders them less rigid than natural and liable to yield to the increasing weight of the body. The deformity of the chest produced in this manner may be so great as to seriously interfere with the functions of the heart and lungs. The bones of the head are never deformed, though rachitic children have frequently large heads, and the fontanelles are late in closing. During the progress of the disease the patient is pale and languid, and has a deficient or irregular appetite. It is very rarely fatal; after an uncertain period the appetite returns, the child recovers strength and flesh, and the bones attain their natural firmness; in after life the bones affected are found to be unusually hard and compact.—The treatment of rickets is mainly by a nutritious, digestible diet, fresh air, suitable clothing, and passive exercise. Tonics and chalybeates may be employed, and the tepid salt-water bath may be found useful.

RICORD, Philippe, a French physician, born in Baltimore, Md., Dec. 10, 1800. His father had come to the United States in 1790. In 1820 the son went to Paris, where he received his medical degree in 1826. He first practised at Olivet, near Orleans, and later at Croüy-sur-Oureq. From 1831 to 1860 he was surgeon-in-chief of the *hôpital du midi* in Paris. He has specially devoted himself to venereal diseases, his works on which have a wide reputation.—**ALEXANDRE**, his brother, born in Baltimore in 1798, received the degree of M. D. at Paris in 1824, and is author of several works on medicine and natural history.

RIDLEY, Nicholas, an English bishop, born at Wilmontswick, Northumberland, about 1500, burned at the stake in Oxford, Oct. 16, 1555. He graduated at Pembroke hall, Cambridge, in 1518, and in 1524 took holy orders. In 1527 he went to study at the Sorbonne, and was afterward at Louvain till 1529. On his return to Cambridge he was chosen under treasurer of the university. He became domestic chaplain to Archbishop Cranmer in 1537, vicar of Herne in Kent in 1538, and master of his college in 1540. He preached against the use of images and holy water, and gradually became a strenuous supporter of Protestant doctrines. At the instigation of Bishop Gardiner he was accused of preaching against the six articles, but the accusation being referred to Cranmer, he was acquitted. In 1545 he was made a prebendary of Westminster, and in 1547 bishop of Rochester. He sat on the commission that deprived Bonner of the bishopric of London, and in 1550 was appointed his successor; he also shared in the deposition of Bishop Gardiner. He assisted Cranmer in preparing the 41 articles. Having sought an interview with the princess Mary, he expressed his views very freely, and requested permission to preach before her, which was peremptorily refused. Moved by a sermon of Ridley's, Edward VI. converted Grey Friars and St. Bartholomew's priories, with their revenues, into charitable institutions, and his own house of Bridewell into a compulsory workhouse for such as were in distress through wilful idleness. In a sermon preached at St. Paul's Cross Ridley espoused the cause of Lady Jane Grey, and warned the people of the evil that would follow to Protestantism if Mary should come to the throne. On Mary's accession he was at once arrested and committed to the tower (July, 1553), and in April, 1554, was taken to Oxford, to attend a discussion on the real presence. At its close he was with Cranmer and Latimer adjudged an obstinate heretic, and confined at Oxford; and after many attempts to induce him to recant, he was led to the stake with Latimer. His works were collected by the Parker society (1 vol. 8vo, 1841).

RIDOLFI, Roberto, an Italian conspirator, born in Florence about 1520. He settled in London as a merchant and banker in 1554, acted there as secret agent for the pope and other

continental princes, and was engaged in several conspiracies against Queen Elizabeth. In 1569 he was imprisoned for a month and fined. In 1571 he visited Brussels, Paris, Rome, and Madrid, bearing credentials of disputed authenticity from Mary queen of Scots and the duke of Norfolk, empowering him to solicit aid to dethrone Elizabeth, and a papal decree annulling the forced marriage of Mary with Bothwell. The duke of Alba received him coldly; the pope gave him money and recommended him to Philip II. of Spain. At Madrid, where he arrived July 3, 1571, he laid before the king and six of his chosen councilors a plan for assassinating Queen Elizabeth, which he declared to have been entertained by the English Catholics and approved by the pope. This assertion, to which the pope's letter of commendation gave some color, induced the king to give a partial assent to the plot in spite of Alba's urgent objections. But meanwhile the intrigue was discovered in England and the chief conspirators were brought to punishment. In December, 1874, on occasion of the Gladstone-Manning controversy, Lord Acton accused Pius V. of complicity in the contemplated assassination of Queen Elizabeth, while writers on the opposite side have labored to show that the pope merely approved of her being dethroned, but knew nothing of the plot against her life. Ridolfi, after the death of the duke of Norfolk and of Mary queen of Scots, continued his intrigues on the continent; but little is known of his subsequent career.

RIEDEL. **I. Friedrich Adolph von**, baron, a German general in the British service, born at Lauterbach in the grand duchy of Hesse, June 3, 1738, died in Brunswick, Jan. 6, 1800. He left his studies at Marburg to join the Hessian regiment in the British service, distinguished himself at the battle of Minden in 1759, and in 1776 was major general in command of the division of 4,000 Brunswickers which formed part of the German mercenary force employed by England in the American revolutionary war. Landing at Quebec June 1, he spent a year in Canada, exercising his men in the Indian mode of warfare. Having accompanied Burgoyne on his march to Albany, he rendered efficient service in the capture of Ticonderoga, and secured the British victory the day following at Hubbardton by bringing up reinforcements. In the first action at Saratoga, Sept. 19, 1777, by a timely forced march through the woods, he saved the army of Burgoyne from annihilation. After the second engagement, Oct. 7, he advised a retreat, and had his counsel been taken Burgoyne's escape into Canada might have been effected. After the surrender Riedesel accompanied his commander-in-chief to Albany. With the other German prisoners he reached Cambridge, Mass., Nov. 7, 1777, whence in the following year he was transferred to Virginia. On being exchanged in

the autumn of 1780, he was placed by Clinton in command of Long Island. In August, 1783, he returned to Germany. Having been made lieutenant general in 1787, he commanded the Brunswick contingent sent to Holland to support the cause of the stadtholder. At the time of his death he was commandant of the city of Brunswick. His "Letters and Military Journals in America," edited by Max von Eelking, has been translated by William L. Stone, with a memoir by the translator (2 vols. 8vo, Albany, 1868). **II. Friederike Charlotte Luise**, wife of the preceding, born in Brandenburg in 1746, died in Berlin, March 29, 1808. She was a daughter of the Prussian minister Masson, and was married at the age of 16. She followed her husband to America, joining him in Canada, and was his constant companion during his stay in this country. In her frequent correspondence with her mother her adventures were graphically and minutely described. These letters were published by her son-in-law Count Reuss, under the title of *Voyage de mission en Amérique, ou Lettres de Mme. de Riedesel* (Berlin, 1799; English by William L. Stone, 8vo, Albany, 1867).

RIEL, Louis. See MANITOBA, vol. xi., p. 114.

RIENZI, Nicola Gabrini, commonly called COLA DI RIENZI, "the last of the Roman tribunes," born in Rome about 1312, assassinated Oct. 8, 1354. He was a notary, but claimed illegitimate descent from the imperial house of Luxembourg, was well educated, of imposing presence, and gifted with extraordinary powers of eloquence. The removal of the papal see to Avignon in 1309 had left Rome a prey to contending factions of nobles, whose houses were fortified castles, and whose armed dependants kept the city in a constant turmoil. On the accession of Clement VI. in 1342, Rienzi was included in the deputation sent to Avignon to urge the pope to return to his see. Petrarch, who headed the deputation, conceived an admiration for Rienzi, to whom he afterward addressed the ode commencing *Spirto gentil*. The pope showed no disposition to revisit Rome, and Rienzi, despairing of any alleviation of the public calamities through the ecclesiastical power, and eager to lead the people to liberty, proceeded by flattering and deceiving the nobles to disarm their suspicions. He submitted to various kinds of indignity to advance his end, and imitating Brutus, in his own words, "made himself a simpleton and a stage player, and was by turns serious or silly, cunning, earnest, and timid, as the occasion required." On the day after Ash Wednesday, 1347, he caused a scroll to be affixed to the doors of the church of San Giorgio in Velabro, on which was inscribed: "Ere long Rome will return to her good estate." On the succeeding vigil of Pentecost the people were summoned to repair to the capitol on the following day. Rienzi passed the night in the church of Sant' Angelo, where he heard the thirty masses of the Holy Ghost, by whom he said

his acts were inspired, and at 10 in the morning issued forth in complete armor, bare-headed, and surrounded by 25 sworn confederates. By his side was the bishop of Orvieto, the pope's vicar, and he was followed by a guard of 100 men-at-arms. The procession, escorted by shouting multitudes of citizens, ascended the capitol, where the "laws of the good estate" were read to the people, providing for the public security in general. A guard was established for the protection of the citizens, and of the shipping and commerce on the Tiber; the right of the nobles to keep strongholds within the city was abolished; all places of defence were to be delivered to the delegates of the people; granaries were to be opened; the poor were assured of alms, and the magistrates were bound to administer justice according to law. The people adopted the constitution by acclamation, and Rienzi, being invested with power to establish the good estate, assumed the title of tribune in the following words: "Nicholas, by the grace of Jesus Christ, the severe and merciful, tribune of freedom, peace, and justice, the deliverer of the Roman republic." The nobles, awed by this sudden revolution, surrendered their fortresses, and gave in their submission. Embassies from Florence, Perugia, Siena, and many other cities of Italy were sent to Rome to congratulate Rienzi on his good work, and to offer substantial assistance; and several powerful Christian sovereigns paid him equal deference. He himself sent an embassy to the pope to ask his approbation; and as an evidence of his submissive reverence for the papal authority, he associated the bishop of Orvieto in office with him, taking care however that the honor should not be accompanied by any control of the affairs of government. Rienzi strove to augment his importance by processions, pageants, and public spectacles; spared nothing which would minister to his pomp and private luxury; and caused himself and his wife to be waited upon by the lords and ladies of his court. On Aug. 1 he was knighted in the Lateran church, and after the ceremony summoned all potentates, ecclesiastical or secular, who presumed to contest the prerogative of Rome to elect the emperor, to appear in the city at the ensuing Pentecost. On Aug. 15 he caused himself to be crowned in the church of Sta. Maria Maggiore with seven crowns, symbolizing the seven gifts of the Holy Ghost, under whose special influence he still claimed to act. His splendid processions gradually palled upon the public taste, and the populace began to murmur at the large expenditures from the public treasury to support the extravagance of their tribune. The nobles, whom he alternately threatened and caressed, finally banded together, and, having recovered several of their strongholds, appeared in arms before the city. By the imprudence of his enemies he gained a victory as surprising to himself as to others, and more than 20 of the

Colonnas, Orsinis, Savellis, and other noble families perished in battle or in flight. Instead of following up his advantage, he allowed his enemies to gather strength while he wasted his time in idle pageantries. The pope declared against him, and the people, alarmed by their rapidly increasing taxes, broke forth into open murmurs, which he was unable to quell, notwithstanding he restricted his extravagance and dropped his most ostentatious titles. At this juncture the freebooting count of Minorbino entered the city and fortified himself in one of the palaces of the Colonnas, whence he refused to retire when summoned by Rienzi. The latter called the armed citizens to his assistance, and, meeting with no response, solemnly abdicated his power, and took refuge in the castle of Sant' Angelo, Dec. 15, 1347, whence he escaped in the disguise of a monk. He took refuge among the Franciscans in the fastnesses of the southern Apennines, with whom he remained two years and a half as a tertiary of the order. During the jubilee celebrated in 1350 he is said to have appeared in the disguise of a pilgrim among the multitudes who flocked to Rome; and soon after, at the instigation, he tells us, of Fra Angelo, an inspired hermit, who informed him that the Father and the Son had ceased to rule in the world, and that the age of the Holy Ghost was at hand, he went to the court of Charles IV. at Prague, and exhorted him, in accordance with the prophecy of Fra Angelo, to undertake the conquest of Italy, in which he assured him none could be of so much service as himself. The emperor, amazed at the ambitious schemes and heretical doctrines of Rienzi, ordered him into custody, and finally sent him a prisoner to the pope at Avignon. A commission of ecclesiastics was appointed to try him, but their labors seem never to have been prosecuted with energy. Meanwhile Rome had returned to its former state of anarchy, and Innocent VI., the successor of Clement, determined, as a means of restoring the papal authority in the city, to send Rienzi thither. In the summer of 1354 he reentered Rome in the capacity of a senator, by the appointment of Cardinal Albornoz, the papal legate. Unwarned by adversity, he returned to his old pomp and luxury, and established an unmitigated tyranny. He was defied by the refractory Colonnas in their castle of Palestrina, against which he conducted a tedious and expensive but unavailing siege. The execution of Fra Moneale, a well known captain of a free company, from whose family he had received pecuniary assistance, and whose property he appropriated to his own use, filled the citizens with horror; and on his attempting to levy a fresh tax to pay his troops, a popular insurrection burst forth. Rienzi took refuge in the capitol, and, being deserted by his guards, appeared upon a balcony in armor, grasping the standard of the people, but was driven back by a shower of stones. Finally, in the disguise of a door-

keeper, he was arrested and led to the foot of the capitol stairs, where, while in the act of addressing the people, he was run through the body by Cecco del Vecchio, an artisan, and was forthwith despatched by a hundred weapons, his head cut off, and his body treated with shameful indignities.—An important series of letters, addressed by Rienzi to the emperor and the archbishop of Prague after his first fall, and vividly illustrating his character, was discovered by Pelzel, the historian of Bohemia, in the last century, and was in 1841 published in German by Dr. Papencordt, under the title of *Cola di Rienzi und seine Zeit* (Hamburg and Gotha). Some of them are given in Hobhouse's "Illustrations to Childe Harold." The story of Rienzi forms the groundwork of one of Bulwer's best known novels.

RIESENGBIRGE (Giant mountains), a range of mountains partly separating Prussian Silesia from Bohemia, and with the Lusatian range forming a continuation E. of the river Elbe to the Erzgebirge range W. of that river. The Riesengebirge belong to the N. W. division of the Sudetic mountain system, and pursue a S. E. course from the sources of the Bober to those of the southern Neisse until they are merged in the Glatzergebirge, of the Sudetic mountains proper. The range extends about 75 m., with a breadth of 30 m., and is of the same general geological structure with the Erzgebirge, the rocks being chiefly metamorphic slates and granites, and productive in a similar variety of valuable ores. Those of iron are especially abundant, and some of the earliest establishments for producing that metal were in this region. The highest summits are the Schneekoppe, which rises to an altitude of upward of 5,000 ft., and the Hohes Rad, and the Grosse and Kleine Sturmhaube, all of which are about 4,500 ft. high.

RIETSCHEL, Ernst Friedrich August, a German sculptor, born in Pulsnitz, Saxony, Dec. 15, 1804, died in Dresden, Feb. 21, 1861. He studied under Rauch and in Italy, settled in Dresden, and was appointed professor in the academy of fine arts. Among his works are a colossal group of "Mary weeping over the Body of Christ;" statues of Lessing, Goethe, Schiller, and Weber; "Love taming a Panther;" "Love borne by a Panther;" the "Four Hours of the Day;" and busts of Luther and Augustus II. of Poland and Saxony for the Walhalla.

RIFLE (Dan., *Rifle* or *Riffel*, a chamfer; Ger. *reifeln* or *riffeln*, to chamfer or groove), a term applied solely until within the past 25 years to small arms, the surfaces of whose bores are spirally grooved to increase the accuracy of their fire. Rifles are supposed to have been invented in the latter part of the 15th century, by Gaspard Zöllner of Vienna. They are known to have been used in target firing at Leipsic in 1498. The first rifles were made with their grooves parallel to the axis of the bore, and although no increased accuracy was

given to the fire by such grooving in theory, yet in practice the firing was better, because the grooves allowed the windage to be diminished, and formed receptacles for the residuum of the firing, which in smooth-bores lodged on the surface of the bore, causing wild shooting after a few discharges. The effect of spiral grooving was probably discovered accidentally, and the date of the discovery cannot be determined. In 1563 a law of the Swiss canton of Bern prohibited the use of arms with spiral rifling in target shooting, on account of the discord which such arms produced among the competitors. Some accounts name as the inventor Augustin Kutter of Nuremberg, who died in 1630. The advantages of rifling were first discussed scientifically in "New Principles of Gunnery" (1742), by Benjamin Robins, an English mathematician, who died in 1751. He mentions breech-loading arms as in use in Europe at that time.—That length in the direction of the bore in which the spiral rifling would make one turn is called the "twist," the parts cut out of the surface of the bore are the "grooves," and the spaces between the grooves are the "lands." The grooves are as nearly parallel to each other as they can be made, and generally have a constant inclination to the axis of the bore. In this case the twist is said to be uniform. There is another kind of twist, in which the groove starts from the breech parallel to the axis of the bore, and gradually inclines from this line until it attains the required angle, where it remains constant. This is called a "gaining twist." It is now only used in small pistols, and has little if any advantage over the uniform twist. The centres of gravity and of figure of a lead or iron ball do not generally coincide, and the diameter of the ball of a smooth-bore is necessarily smaller than that of the bore of the piece. It follows from the first fact that the line of direction of the force exerted upon the ball by the powder does not generally pass through its centre of gravity, causing a tendency to revolve about an axis passing through that centre, which axis will not coincide with the axis of the bore or the tangent to the trajectory, thus forming one source of deviation of the projectile from the theoretic trajectory. It follows from the second fact that the ball as it advances through the piece will bounce against the surface of the bore, causing a motion of rotation about some unknown axis; this is another source of deviation. If these sources of deviation be removed, the projectile will move in the theoretic trajectory, and will strike the point aimed at, if the other conditions to attain this end have been complied with. If a barrel be rifled, and the ball so made that projections on its surface precisely fit the grooves of the rifling, the ball in passing through the barrel must receive a motion of rotation about the axis of the bore; and as the axis of rotation will then nearly or quite coincide with the tangent to the trajectory du-

ring its flight, the sources of deviation above mentioned will have been removed. No account is here taken of the tendency of the axis of rotation to continue parallel to its original direction, which (as the path of the ball after it leaves the gun is a curve) gives some deviation from the desired point, as such a discussion involves an abstruse mathematical investigation. If a lead ball be pushed down the bore of a muzzle-loader until it reaches the powder, and then by some means be so expanded that the lead is squeezed into the grooves of the rifling, such a ball will receive in passing through the bore the required motion of rotation. In a breech-loader the lead ball is slightly larger than the bore, and the explosion of the powder upsets it, and forces the lead into the grooves, thus destroying all windage, and giving the necessary motion of rotation about the axis of the bore. Of two balls of the same weight projected from guns, it is evident that that one which presents the smaller surface to the direction of the motion will be less resisted by the air. Hence, other things being equal, the smaller the bore of the gun within practical limits, the less resistance is there to the motion of the ball, or in other words the further the ball will be carried, or technically the flatter will be the trajectory. Formerly the difficulty of loading pieces with small bores prevented the use of small calibres in military arms; but the general introduction of breech-loaders, in which small calibres can be loaded as easily and quickly as large ones, has caused the advantages of small calibres with cylindrical bullets to be recognized, and the calibres of all breech-loading military small arms manufactured within the past ten years range between .5 in. and .4 in. The great majority range between .45 in. and .4 in. It has been mathematically determined that the larger and denser the projectile, the less in proportion is the resistance of the air. It follows therefore that for the same calibre an oblong projectile is less retarded than a spherical one, and that for the same initial velocity the oblong projectile will have a greater range than the spherical one. It has also been mathematically determined that the length of trajectory of a projectile, in which the velocity is reduced by any definite amount, is directly proportional to the product of the diameter and density of the projectile, and inversely proportional to the density of the air. Hence greater ranges are obtained by the use of large and heavy projectiles, in preference to small and light ones, solid shot instead of shells; lead instead of any lighter metal, and long instead of short projectiles. These principles have all been applied in the manufacture of modern rifled small arms; but it is only within the past 30 years that the rifle has come into general use as a military weapon.—Various styles of rifling have been used in the manufacture of military arms, the difference being in the number and shapes of the

grooves and the lengths of the twists. But in general, the grooves are flat, in number from three to seven, and the breadth of the lands less than that of the grooves. In muzzle-loaders the depth of the grooves diminishes from the breech to the muzzle, but in breech-loaders that depth is constant. In muzzle-loaders too, as a very great range was not considered attainable, the twist was gentler than it is in breech-loaders. In the former the twist

FIG. 1.—Whitworth's Small-arm Projectile.

was generally one turn in 60 in. or more; in the latter it is usually one turn in 22 in., and in some arms it is a little greater than that. The intensity of the twist is limited by the danger of causing the ball to "strip" in passing through the bore. About 5 per cent. of the force of the powder is taken up in generating the enormous velocity of rotation made necessary to attain the long ranges of modern arms. Whitworth's rifling consisted in making the bore of the barrel hexagonal in section, with rounded angles, and giving the bore a twist. The effect of this was good, but the difficulty of its manufacture, or rather the ease of manufacture of the cylindrical bore, has caused its general rejection in military small arms. Henry's rifling, which was adopted by the British government for all its small arms, has produced excellent results. Although the section looks as if it might be difficult to bore

FIG. 2.—Henry's Rifling.

it correctly, yet, on account of the peculiar arrangement of grooves, it is no more difficult to make than ordinary rifling.—As small arms became lighter and of more general use in armies, the necessity for a light arm of long range for the use of light troops, sharpshooters, &c., became more apparent. The fire of the ordinary musket or arquebus was too wild for such troops, and the rifle came gradually into use, but the slowness of its fire

prevented its general adoption. In Germany, during the thirty years' war, organized companies of riflemen were used with advantage by William V., landgrave of Hesse-Cassel. In 1645 three regiments were organized in Bavaria, and in 1674 the elector Frederick William of Brandenburg had riflemen distributed among his infantry regiments. In 1740 Frederick the Great organized a small body of light infantry of 60 men armed with rifles, which finally grew into a regiment. France also early made use of sharpshooters or riflemen. In 1689 a French organization existed in which the men were armed with two pistols, a sword, and a rifle called *escopette*. But the rifle, on account of the difficulties in its manipulation, did not grow in favor, and at the commencement of the French revolution no rifle regiments or companies existed in France. The Swiss and Austrians paid much attention to their military rifle organizations during the last half of the 18th century, being forced into that direction by the passionate fondness for the arm which existed in the Swiss mountains and in Tyrol. During the war of the American revolution the Americans, who were obliged to bring every weapon into requisition, made excellent use of their hunting rifles, and were really the first sharpshooters. The British, taught by their dearly bought experience, adopted rifles as an important part of their armament in 1794. Rifled carbines are mentioned in Smith's "Military Dictionary" (1779) as arms "used by the hunters or light infantry." In the new organization the left flank company of each battalion of ten companies was composed of light infantry or riflemen, and received special instruction, the right flank company being grenadiers. The French about the same time (1792), following the same example, introduced new model rifles into their infantry and cavalry armaments. Their accuracy for short ranges was superior to that of the musket; but the shortness of the range, the slowness of loading, the necessity for a peculiar patched ball and for using a mallet, and the fact that no bayonets were used with them, soon caused their abandonment. The consequence was that under Napoleon I. rifles were little used in the French army. But although Napoleon had a low opinion of the rifle as it existed in his day, he had great faith in the improvement of the musket. He therefore designated Col. Pauly at Paris to improve the musket, who in 1812 patented in France what has since been known as the Pauly gun. The cartridge in this gun contained its own means of ignition. In Pauly's shop Dreyse worked. Pauly's gun having been thrown aside on account of its alleged want of simplicity, Dreyse worked on in the direction of the bolt gun, and in 1836 made the first breech-loading needle gun. As Pauly's was the parent gun of all breech-loaders which close the breech with a swinging block, so Dreyse's needle gun is the parent of all breech-

loaders which close the breech with a bolt. In 1826 Lieut. Delvigne of the French artillery invented a rifle with a chamber smaller than the bore. The chamber was connected with the bore by a spherical surface of the

Fig. 8.—Pauly Breech-loader. 1. Vertical section. 2. Elevation. 3. Cartridge.

same radius as that of the ball. The powder having been poured into the chamber from the muzzle, the ball was dropped into the bore, and rested on the top of the chamber. A few blows of the ramrod, with its head hollowed to fit the bullet, squeezed the lead into the rifling grooves without disturbing the powder, and when the piece was fired it was found that the range and accuracy were materially increased, an effect due to the rifling. This idea of Delvigne's, viz., getting the ball to its place on top of the powder in the chamber without other force than its own weight, and then causing it to take the rifling by the action of ramming, was the mother idea of all improvements in muzzle-loading military rifles from that time onward, and in fact may be said to be the first step in modern improvements of rifles. In 1842 France armed ten battalions of chasseurs with rifles made on Delvigne's principle, and at the same time instituted the school of firing for the purpose of educating sharpshooters. This school has been imitated by nearly all other nations. The cartridge for Delvigne's arm was special, and

Fig. 4.—Breech of Delvigne's Rifle (1842).

therefore objectionable; hence Col. Thouvenin invented the *carabine à tige*, in which the bore is of the same diameter from the muzzle to the breech. From the breech projects into the bore a steel rod about $\frac{1}{4}$ in. in diameter, the axis of which is coincident with that of the bore, and its length such that the front end of the rod reaches to the top of the powder charge. The rifle was loaded precisely as was the old musket. The middle part of the ball rested on the front end of the rod, and a few blows of the ramrod squeezed the lead into the rifling. This rifle made a good target at 500 yards. The next step in the improvement of rifled small arms was the introduction of the elongated projectile of Capt. Minié about 1845.

The *carabine à tige* was still used, but the rifling was made more abrupt, having a twist of $6\frac{1}{2}$ ft. instead of 20 ft., an increase necessary on account of the greater weight of the new projectile, and the greater range attained. The rod at the breech (*tige*) was left out. Ranges

FIG. 5.—Breech of Carabine à tige (1846).

of more than 1,300 yards were obtained, and accurate shooting was done at ranges of 900 yards. Grooves had been made in the rear part of the bullet to hold the lubricant. In order to simplify the shape of the ball these grooves were afterward left off; but the shooting was materially diminished in accuracy by the omission, and the experiment showed that such grooves made the very resistance which was necessary to keep the axis of the long projectile coincident with the tangent of the trajectory through its flight; or in other words, they kept the bullet from turning end over end. About 1849 Capt. Minié invented a bullet which had in its rear a recess of a truncated conical form lined with a tin cup something like a small thimble. This recess made the sides of the bullet thin, so that the effect of firing the charge was to press the tin cup into the bullet, forcing the lead into

the grooves of the rifling. This invention caused the abandonment of the rod in the *carabine à tige*, and gave an impetus to the introduction of rifles into all European armies, so that by 1855 the infantry firearm in those armies was the rifle; the old smooth-bore mus-

kets were rifled, and used the Minié bullet, becoming rifles in all respects, and retaining the ease of loading of the smooth-bore. The United States had for 30 years before that time kept a small supply of military rifles, manufactured at the Harper's Ferry armory. Their calibre was $\cdot54$ in., and their weight about $9\frac{1}{2}$ lbs. The rifling was in three grooves, each $\cdot36$ in. broad, with a constant twist, making one turn in 10 ft. The depth of the grooves was $\cdot005$ in. at the muzzle and $\cdot008$ in. at the breech. The ball, which was spherical and patched, weighed $\frac{1}{2}$ oz. or 220 grs., and the powder charge weighed 75 grs. These rifles were used in some frontier campaigns, and by a few regiments in the Mexican war. They were altered about 1855 by increasing the calibre to $\cdot58$ in., and by making the grooves $\cdot3$ in. broad, $\cdot005$ in. deep at the muzzle, and $\cdot013$ in. deep at the breech. In 1855 the United States adopted a new model rifle musket, which has been known since as the Springfield rifle. The calibre was $\cdot58$ in., and the weight with bayonet about 10 lbs.

The rifling was in three grooves, each $\cdot3$ in. wide, $\cdot005$ in. deep at the muzzle, and $\cdot015$ in. deep at the breech. The twist was uniform, making one turn in 6 ft. The bullet was cylindrical-conical with expanding base, and weighed 500 grs. The powder charge weighed 60 grs. From this date the rifle became the infantry arm of the United States, although the suddenness of the outbreak of the civil war of 1861-'5 made it necessary to bring into use all the small arms then belonging to the United States, smooth-bores as well as rifles.—All attempts to improve muzzle-loading small arms may be considered to have ceased after 1861, the fact that breech-loaders were soon to supersede them as infantry arms having become apparent to all military authorities. In 1814 Pauly's invention was examined by a commission of which Brillat-Savarin was president, and an exhaustive series of experiments was made. The commission reported that troops armed with these guns would have a very great advantage over an enemy armed with muzzle-loaders, because the Pauly guns could be loaded and fired without slackening the march; that they could be fired more rapidly than muzzle-loaders, would carry further, and required less powder; that rain or dampness would not affect the fire; that they never hung fire; that the charge was easily withdrawn; that a ramrod was not required; and that, other things being equal, the range was greater than that of a muzzle-loader. Add to these the further advantage that they could be loaded while the soldier was lying down, and we have all the merits claimed for the breech-loaders of the present day. But Europe was at that time exhausted with the wars of Napoleon, and little attention was given to the invention. About 1811 a breech-loading rifle was invented in the United States by John H. Hall, and after trial at the Washington arsenal and at Fortress Monroe in 1818-'19, a large number were ordered to be made at the Harper's Ferry armory. They were manufactured there under the direction of the inventor, who first introduced the system of making the parts of the arm interchangeable, and was the first or among the first to use the drop-hammer for stamping out the parts by one or two blows. Carbines were made after the same invention, which were used by the mounted troops of the United States until about the time of the Mexican war. Although these rifles were very strong shooters, there were some elements of danger about them, and they never were favorites with the troops. This is the first instance of the successful introduction of a breech-loader into a military service. The Hall rifle was made to use both the flint and the percussion locks. Taking an ordinary muzzle-loader, and cutting the barrel in two about 6 in. or less in front of the breech, and arranging the rear piece on a hinge or trunnions so that it may be raised high enough to expose the bore, we have nearly the Hall rifle. This movable piece could be

clamped so that its bore and that of the barrel were coincident, and it made the chamber. To load the piece, the front end of the chamber

FIG. 8.—Hall's Rifle.

was thrown up by a trigger under the stock. The cartridge was then inserted, the chamber pressed back to its place, where it was held by a trigger and spring, and after priming or capping, the piece was ready for firing. A breech-loading rifle was invented in Norway about 1838, and between 1839 and 1845 extensive preparations were made with it by the government of Sweden, resulting in the conclusion that it was superior in all respects to muzzle-loading arms.—In 1841 Prussia decided to arm the troops with the *Zündnadelgewehr* or needle gun, and in the course of a few years its whole army was furnished with this arm. Its first uses in actual service were in the revolution of 1848 and the first Schleswig-Holstein war, where its superiority to the muzzle-loader was demonstrated. The decisive Prussian victory of Sadowa in the Austrian war of 1866 was at first attributed wholly to the fact that the Prussians had the needle gun, while the Austrians had only muzzle-loaders; and a great impetus was given to the introduction of breech-loaders in all European armies. In France a needle gun was adopted which was

a bolt to which is attached a handle which acts in keeping the breech closed, precisely as does the handle of a door bolt in keeping the bolt in place when it is shot. The bolt traverses forward and back in an iron receiver which is screwed to the barrel. The lock and needle are enclosed in the bolt. The spring, like that in nearly all bolt guns, is of spiral steel wire. Supposing the piece unloaded, to load it, the needle is pulled back by the thumb piece in rear; then the handle is turned to the left, the bolt withdrawn, and the cartridge inserted. The bolt is pushed forward, the handle turned to the right against its stop in the receiver, and after cocking by pushing forward the thumb piece, it is ready for firing. The fulminate is just in rear of the wad at the base of the bullet, so that the needle passes through the whole powder charge before it strikes the fulminate. The cartridge envelope is papier maché. The calibre of the rifle is about .6 in.,

FIG. 10.—French Chassepot.

1. Gun complete. 2. Section showing lock and rifling of gun ready to fire.
3. Cartridge.

and the number of grooves is four. There is a great leak of gas from this rifle. The gas check is made by the contact between the bolt and the rear part of the chamber, and is not sufficient, particularly as this contact becomes more imperfect as the gun is used. In the Chassepot, or French military rifle, the breech action is in several respects like that

FIG. 9.—Prussian Needle Gun.

1. Gun complete. 2. Section showing working parts of lock, gun ready to fire.
3. Cartridge.

in all respects an improvement on that of the Prussians, called the Chassepot after the inventor. The needle-gun breech action consists of

of the preceding, having a bolt handle by which the bolt is held in place, the latter containing the lock and needle. The fulminate is in a paper wad which forms the rear of the cartridge envelope. The gas check is a cylindrical India rubber, which is pressed against the surface of the chamber when the explosion takes place, and theoretically forms an efficient obstacle to the passage of the gas. The cartridge envelope is silk or linen, and the calibre is .433 in. (11 millimetres). The num-

ber of grooves is four. These are the two principal breech-loaders in use which do not employ the metallic envelope cartridge, and it is notable that the greatest war of modern times was fought with these two arms, metallic cartridge arms having been scarcely used in any of its great battles.—The civil war in the United States stimulated the invention of breech-loading arms. Nearly all of these used the metallic cartridge, and some displayed great inventive talent. Shortly before the war several breech-loaders were tested by the United States which used the detached percussion cap. Among these are the Burnside, Cosmopolitan, Gallagher, Joslyn, Merrill, Maynard, Smith,

FIG. 11.—Spencer Magazine Gun.

Lindner, and Sharps. The last named has been altered to use the metallic cartridge, and is still in use. The others have generally been discarded, and are not in use as military arms. During the civil war the Spencer rifle, a magazine gun, was introduced, and was extensively used by the Union cavalry. It contains a magazine in the butt of the stock, holding seven cartridges, and by the movement of the trigger guard used as a lever the cartridges are admitted to the chamber one by one. The same movement ejects the shell of the exploded cartridge. When the magazine is exhausted, it can be replaced by another, or be reloaded, or the rifle may be used as a single breech-loader, the magazine being previously shut off. In the Henry gun, an American invention, the magazine is under the barrel, and parallel to it.

FIG. 12.—Winchester Repeating Arm.

It contains 17 metallic-cased cartridges, which can be brought successively into the chamber by moving the lever under the stock. It can

also be used as a single breech-loader by shutting off the magazine. This gun has been altered by O. F. Winchester, and is now called

FIG. 13.—Remington Rim-fire Rifle.

the Winchester gun. The Ball, Fogarty, and Gardner guns are also magazine guns. The Remington gun is a single breech-loader using metallic-cased cartridges. An iron receiver made to correspond externally to the shape of a gunstock is screwed to the breech of the barrel; in this are contained the breech block and lock. Supposing the piece to have been discharged, it is loaded as follows: 1, it is cocked; 2, the breech block is pulled back by the handle at its right side, ejecting the shell of the exploded cartridge; 3, the cartridge is inserted; 4, the breech block is pushed back to its place, closing the breech. The gun is then ready for firing. The hammer has a pro-

FIG. 14.—Springfield Breech-loader.

1. Vertical Section of Breech-loading System. 2. Gun complete. 3. Cartridge.

jection which passes under the breech block when it is down, or closing the breech, and prevents the block from flying back when the explosion takes place. The firing pin passes through the breech block from the nose of the hammer to the percussion cap in the base of the cartridge shell. This rifle is used by the United States navy, and has been adopted by Egypt, Spain, and some other nations. It has various calibres and riflings, and is arranged for rim-fire and central-fire cartridges. The Springfield breech-loader, which has been adopted by the United States for the army and militia, is in external appearance like the Springfield muzzle-loader, having nearly the same stock and side lock. The breech action consists of a receiver screwed to the breech of the barrel, and a breech block which when it

closes the breech lies in the receiver. To open the breech, the breech block moves upward and forward about a hinge in its front and on top of the barrel. The movement of the hinge in opening the breech block ejects the shell of the exploded cartridge by a combined cam and spring. In the rear of the breech block is a cam with an eccentric handle used for lifting the block, and so arranged that unless the block is closed the hammer cannot strike the firing pin, but will merely strike the handle. The firing pin goes through the breech block in an inclined direction from the nose of the hammer at the side to the centre of the rear of the chamber, where it strikes the head of the cartridge, exploding the fulminate when its rear end is struck by the hammer. This rifle was selected by a board of officers of the army in 1873 from about 100 competitors. Its calibre is .45 in., and it has three grooves equal in width to the lands, and a twist of 22 in.—

FIG. 15.—Martini-Henry Gun.

The rifle adopted for the military service by the British government is the Martini-Henry, in which the breech action is the invention of Martini, and the rifling that of Henry (not the inventor of the Henry gun), which has already been described. The Martini breech action appears to have been taken from the Peabody gun, an American invention. In the latter the breech block revolves about an axis at its rear end, and the front end falls to open the breech. In the act of falling it moves a bent lever which ejects the shell. The motion of the breech block in the Martini is the same as that in the Peabody; but the Martini breech block contains the lock, differing in this respect from the Peabody, in which the ordinary

FIG. 16.—Peabody Rifle.

side lock is used. Turkey has adopted the Martini-Henry gun. The calibre of this rifle is .45 in., the rifling the Henry, with seven grooves.

The twist is 22 in. The first step made by the British government in the direction of breech-loading small arms was in the alteration of the

FIG. 17.—Snider Breech Action Rifle.

Enfield muzzle-loader to the breech-loading system by the Snider plan, about 1866. The breech block in this system revolves about an axis parallel to the axis of the bore, and at its right. The firing pin passes obliquely from the nose of the hammer through the breech block to the centre of the base of the cartridge. In 1869 Russia ordered from the United States 30,000 metallic-cartridge rifles, consisting of a combination of the Springfield breech-loader and a spiral spring lock. This was the first movement in arming an enormous army like that of Russia with metallic-cartridge arms. The questions of the kind of cartridge and diameter of bore and rifling were carefully studied by the Russian officers in the United States under Maj. Gen. Gorloff, and their results were adopted by the Russian government. The calibre adopted was .42 in.; the ball

FIG. 18.—Gorloff Russian Breech-loader.

weighed 380 grs., the powder 77 grs.; and the cartridge case was brass, central fire. There were six grooves, each .175 in. broad, and the twist was 22 in. Major Pieri of the French army has adopted the same calibre in a breech-loading rifle lately invented by him. In this arm the rifling is peculiar, and there is no trigger nor trigger guard on the lower side of the stock. The rifle is fired by touching a thumb piece on the upper side of the stock, behind the breech action. In other respects it is similar to the Chassepot. Afterward Russia adopted in place of the Gorloff a bolt gun which takes the same cartridge, the invention of the American Col. Hiram Berdan. Since the Franco-German war, Germany has changed her needle gun, with paper or linen

envelope cartridges, for another with calibre .433 in., using a metallic-shell cartridge; and France has commenced the introduction of an altered form of the Chassepot which will make it available for use with the metallic cartridge. It may be said therefore that all civilized nations are now using breech-loading, metallic-cartridge arms.

TABLE SHOWING THE VARIETIES OF BREECH-LOADING RIFLES USED IN THE MILITARY SERVICES OF THE NATIONS NAMED.

NAME OF NATION.	NAME OF RIFLE.	DESCRIPTION OF BREECH ACTION.	Shots per minute.	Weight of cartridge, gra.	Weight of rifle without bayonet, lbs.	Range, yards.	Calibre, inches.	REMARKS.

The extreme accurate range of military breech-loading rifles now in use by nearly all nations is about 1,000 yards. An expert shot will strike a man at this distance three times out of four. It is claimed for the Russian rifle described above, that an expert will place every bullet within a space 3 ft. high by $1\frac{1}{2}$ ft. broad at 1,000 yards distance. The range of magazine or repeating rifles does not in general exceed 500 yards. In order to place a large number of charges in the magazine, the charge is kept small, in some degree sacrificing range to rapidity of fire. The range of rifled pistols is about 100 yards. Thirty years ago the range of the musket, which was the infantry arm in use in all armies, was 200 yards, and the tactics of the three arms, infantry, cavalry, and artillery, dimensions of forts, &c., were all determined upon that basis. It is evident that the great increase of range due to the present style of breech-loading weapons must materially increase the distances at which the fire of hostile bodies of infantry becomes deadly, and must therefore involve a radical change in tactics. This change is now a subject of discussion among the most accomplished soldiers, but has not yet been determined.—See Robins, "New Principles of Gunnery" (London, 1742); Thiroux, *Instruction théorique et pratique d'artillerie* (Paris, 1842); Roret, *Manuel de l'armurier* (1852); Chesney, "Observations on Fire-arms" (London, 1852); Wilcox, "Rifles and Rifle Practice" (New York, 1859); L'Haridon, *Catalogue du musée d'artillerie* (Paris, 1864); Greener, "Modern Breech-loaders" (London, 1870); Favé, *Études sur le passé et l'avenir de*

l'artillerie (Paris, 1871); Mattenheimer, *Die Rückladungsgewehre* (Darmstadt and Leipsic, 1872); and Wingate, "Manual for Rifle Practice" (New York, 1875). (For rifled cannon, see ARTILLERY, and CANNON.)

RIGA, a city of Russia, capital of Livonia, on the right bank of the Dvina, about 8 m. from the gulf of Riga, and 300 m. S. W. of St. Petersburg; pop. in 1867, 102,043, of whom 47,000 were Germans, 25,000 Russians, and the rest chiefly Letts. It is the seat of the authorities of the Baltic provinces, and next to St. Petersburg and Odessa the greatest commercial emporium of Russia. The walls of the city were in 1857 converted into promenades; the citadel was razed in 1867, and no fortifications remain excepting Fort Dünamünde for the protection of the harbor. There are three suburbs: the Moscow suburb, inhabited chiefly by Russians; the St. Petersburg, by Germans; and the Mitau suburb. St. Peter's, the principal of the nine Lutheran churches, has a tower 470 ft. high, and there are four Greek and several other churches and a synagogue. There are two gymnasiums, a new polytechnic institute and school of navigation, and various other schools, and a conservatory of music was established in 1875. One of the finest public buildings is the exchange. The arrivals of vessels in 1873 were 3,177, and the departures 3,181. The imports amounted to 19,611,660 rubles, including coal, salt, iron, and miscellaneous articles; the exports to 20,153,453 rubles, consisting chiefly of flax, hemp, timber, grain, and tobacco. The registered shipping is about 100 vessels, about one fourth

steamers. There are in Riga and vicinity nearly 100 manufactories of woollen, cotton, and other goods, and many ships are built.—The city was founded in 1201 by the Livonian bishop Albert von Apeldern, who here established the order of knights sword-bearers, which in 1237 united with that of the Teutonic knights, and the latter for a considerable time wielded supreme authority together with the see of Riga, which was early raised to the dignity of an archbishopric. The city, however, paid but limited obedience to its rulers, having grown prosperous and become a member of the Hanseatic league. The last of the archbishops, the margrave William of Brandenburg, favored the reformation, which had been introduced under his predecessor (about 1530). The city was subsequently a protectorate of Poland, excepting from 1561 to 1581, when it was free. In 1621 it was conquered by the Swedes, and in 1710 by Russia, but without losing any of its ancient privileges.

RIGDON, Sidney. See MORMONS, vol. xi., p. 833.

RIGG, James H., an English clergyman, born in Newcastle-upon-Tyne in 1821. He entered the Wesleyan ministry in 1845, and soon exerted great influence. In 1852 he published a series of papers entitled "Wesleyan Connectionalism and Congregational Independency Contrasted," and was appointed editor of the "London Quarterly Review," the Wesleyan organ; some of his contributions to which were collected under the title "Modern Anglican Theology" (8vo, 1857). Since 1868 he has been principal of the Wesleyan normal college at Westminster, and since 1870 a member of the London school board. He was a delegate to the conference of the evangelical alliance in New York in 1873, and has received the degree of D. D. from Dickinson college, Pa. His principal works are: "The Sabbath and the Sabbath Law, before and after Christ;" "The Relations of Wesley and Wesleyan Methodism to the Church of England;" "Wesley's Character and Opinions in Early Life;" "John Wesley in Mature and Later Life;" "Essays for the Times" (8vo, 1866); and "National Education in its Social Conditions and Aspects, and Public Elementary School Education, English and Foreign" (8vo, 1873).

RIGHINI, Vincenzo, an Italian composer, born in Bologna, Jan. 22, 1756, died there, Aug. 19, 1812. He studied counterpoint under Martini, and commenced as a singer at Parma; but his reputation as a composer soon surpassed that as a vocalist, and after three years at Prague he entered the service of Joseph II. at Vienna, remaining eight years. He was afterward successively chapelmaster to the elector of Mentz, and director of music at the royal theatre in Berlin. He composed 20 operas, mostly on classical subjects, and one entitled *Don Giovanni, ossia il convitato di pietra*, having a libretto similar to that afterward used by Mozart. He also wrote many arias and

cantatas, a *messe solennelle*, and some instrumental works. His operas have fallen into disuse, but many of their arias are still sung.

RIGI, or **Righi**, an isolated mountain of Switzerland, in the canton of Schwytz, between the lakes of Zug and Lucerne. The highest point, the Rigi Kulm, is 5,902 ft. above the sea, or about 4,500 ft. above the lake of Lucerne. The view from this summit is one of the most extensive in the Alps, embracing most of E. and N. Switzerland and the Jura mountains, and extending far into Swabia. There are numerous hotels and sanitariums on the mountain, which attract as many as 40,000 visitors annually. The summit is accessible by roads from various points at the base. In 1873 a railway on the plan of the one at Mt. Washington, N. H., was completed to the Rigi Kulm. It starts from Vitznau, on Lake Lucerne, on the S. side of the mountain, and its grades range from 7 to about 30 in 100.

RILEY, a N. E. county of Kansas, bounded E. by the Big Blue river, and S. and S. W. by the Kansas and Republican rivers; area, 654 sq. m.; pop. in 1870, 5,105. The Kansas Pacific railroad passes along the S. border. The surface is diversified and the soil fertile. Limestone and sandstone are found. The chief productions in 1870 were 78,166 bushels of wheat, 405,277 of Indian corn, 57,730 of oats, 43,086 of potatoes, 111,590 lbs. of butter, and 15,740 tons of hay. There were 2,299 horses, 2,192 milch cows, 4,458 other cattle, 2,190 sheep, and 1,758 swine; 1 flour mill, 3 saw mills, 2 breweries, 3 manufactories of saddlery and harness, and 3 of tin, copper, and sheet-iron ware. Capital, Manhattan.

RILEY, Charles Valentine, an American entomologist, born in London, England, Sept. 18, 1843. At 17 he came to America, and after farming for three years was for nearly five years editor of the entomological department of the "Prairie Farmer" at Chicago. In 1868 he was made state entomologist of Missouri, and has since then made annual reports on its insects. In the same year he began with Benjamin D. Walsh, state entomologist of Illinois, the "American Entomologist," a monthly magazine. Among the more noteworthy results of his labors are the tracing of the history of the Colorado potato beetle (1863); the discovery of a 13-year brood of the 17-year or periodical cicada (1868); the discovery of the grape *phylloxera* in American vines, and of its identity with the destructive insect of southern France (see PHYLLOXERA); the recommendation to use diluted Paris green against the Colorado potato beetle (1871) and the cotton worm (1873); and the discovery of the yucca moth (*pronuba yuccasella*), by which the North American yuccas are fertilized. In 1873 he was presented with a grand gold medal by the French minister of agriculture and commerce "for services rendered to French grape culture."

RIMINI (anc. *Ariminum*), a town of central Italy, at the mouth of the Marecchia in the

Adriatic, in the province and 30 m. S. E. of the city of Forlì, with which it is connected by railway; pop. in 1872, 33,886. It contains celebrated antiquities, especially a bridge of the finest white marble built under Augustus and Tiberius at the junction of the Via Flaminia and Via Æmilia. The church of San Francesco is of remarkable architecture, and was built by Pandolfo Malatesta, whose family were the local rulers from the beginning of the 13th century to the beginning of the 16th. Rimini possesses one of the largest and finest theatres of Italy.—See *Storia Riminese*, by Tonini (2 vols., Rimini, 1860).

RIMOUSKI, an E. county of Quebec, Canada, bounded N. W. by the St. Lawrence river, near its mouth; area, 4,932 sq. m.; pop. in 1871, 27,418, of whom 25,957 were of French and 880 of Scotch origin or descent. It is watered by streams flowing into the St. Lawrence and into the Restigouche river and bay of Chaleurs, and is traversed by the Intercolonial railway. Capital, Rimouski.

RINDERPEST. See MURRAIN.

RINEHART, William Henry, an American sculptor, born in Frederick co., Md., Sept. 13, 1825, died in Rome, Italy, Oct. 28, 1874. He was apprenticed to a stone cutter, attended the night school of design of the Maryland institute in Baltimore, became foreman of the establishment in which he was employed, and was noted for his fine monumental and mantel work. Opening a small studio, he devoted his leisure hours to modelling, and executed one of his earliest works, "The Woodman." He was in Florence from 1855 to 1858, and on his return to Baltimore brought his bass reliefs "Night" and "Morning." He established a studio there, but soon afterward went to Rome, where he resided till his death. He completed the double bronze door in the capitol at Washington, left unfinished by Crawford. His best works are a "Nymph," "Woman of Samaria," "Indian Maiden," "Rebecca," "Endymion," "Atalanta," "Hero," "Leander," "Antigone," and "Latona." His masterpiece, "Clytie," is in the Peabody institute, Baltimore; his statue in bronze of Roger B. Taney is at Annapolis. He executed more than 100 portrait busts.

RING (Ang. Sax. *hring*), a circular ornament worn on the finger. The finger ring has been more intimately associated with the most important interests of life than any other ornament. In ancient times it was a symbol of authority, and power was delegated by means of it. When "Pharaoh took off his ring from his hand, and put it upon Joseph's hand," he intrusted to him the government of Egypt. Ahasuerus gave his ring to Haman as his warrant for exterminating the Jews; and when he ordered Mordecai to write letters annulling the decree, he took the ring from Haman and gave it to him to seal them with. Signet rings and rings for ornament were worn by all classes of the ancient Egyptians. Many

gold ones have been found in the tombs, and some of silver and of bronze, the latter mostly signet rings. Those worn by the lower classes were usually of ivory or of blue porcelain. The favorite rings of the rich were plain circlets of gold, bearing either a scarabæus or a stone engraved with the name of some deity or king, or with a sacred emblem and legend. Frequently many were worn, sometimes two or three on each finger and on the thumbs. Among the Hebrews the signet ring was an indispensable article of dress, and was perhaps handed down from father to son as a mark of rank and authority (Luke xv. 22). The Hebrew ladies wore rings adorned with precious stones, valuing most those set with rubies, emeralds, and chrysolites. As Homer makes no mention of rings, they are supposed to have been introduced into Greece from Asia subsequent to his time. In the days of Solon every freeman wore a signet ring of gold, silver, or bronze, and it does not appear that the right was ever restricted to any class of the Athenians. At a later period rings were set with precious stones, and were worn as ornaments, some persons displaying several on each hand. Women wore ivory and amber rings. Among the Lacedæmonians only did the law attempt to repress the luxury of wearing gold and jewelled rings, and every Spartan took pride in the use of a plain iron ring.—According to Pliny, the Romans derived the custom of wearing rings from the Greeks, but Livy ascribes its introduction to the Sabines, and Florus to the Etruscans. At first all rings were of iron, and such continued to be worn by many noble families as a distinguishing mark after gold rings had come into common use. For a long time not even the Roman senators wore rings of gold, but they were given to ambassadors at the public expense as a part of their official dress, to be used only on ceremonial occasions. Afterward the privilege was extended to senators, to chief magistrates, and to those of the equestrian order, who were said to enjoy the *jus annuli aurei* or *jus annulorum*. After the battle of Cannæ Hannibal sent to Carthage three *modii* of gold rings which had been stripped from the fingers of the slain Roman knights. Under the empire the right of granting the *annulus aureus* was assumed by the emperors, and even magistrates and governors of provinces conferred the privilege of wearing it upon inferior officers and those whom they desired to honor. In the reign of Tiberius many protected themselves from the consequences of the infraction of certain laws on the plea that they wore the gold ring, in consequence of which an ordinance was passed directing that it should be worn only by freemen whose fathers and paternal grandfathers had possessed a property of 400,000 sesterces. Aurelian gave the right to all the soldiers of the empire, and under Justinian every citizen was entitled to it. With the increase of luxury the

Romans, like the Egyptians and Greeks, covered their fingers with rings, wearing one on each joint, not excepting even the thumb. According to Martial, Charinus wore 60 rings, or six on each finger. Fops had rings to suit the seasons, light ones for summer and heavier ones for winter. The Romans introduced from Egypt the custom of engraving animals on their signets; afterward the portraits of heroes and of princes took their place; and later, indelicate symbols were frequently displayed. Rings were often of immense value; that of the empress Faustina is said to have cost \$200,000, and that of Domitia \$300,000. Plain rings were worn originally by the Romans on either hand, but when gems were added they were worn on the left hand. The Jews wore the signet ring always on the right hand, on the middle or the little finger; but with the Egyptians the fourth finger of the left hand was the ring finger.—The early Christians adopted the use of rings. At first they wore simple circles of ivory, bronze, iron, or some other cheap material, and great numbers of these have been found in the Roman cemeteries; but soon this custom degenerated into such an abuse that the fathers of the church, particularly Tertullian, Cyprian, and Jerome, were obliged to inveigh with severity against the prodigality of rings of gold and precious stones. Many of the Christians adorned their rings with symbols connected with their faith,

FIG. 1.

FIG. 2.

such as the cross, the monogram of Christ (fig. 1), the fish (ΙΧΘΥΣ; see Cross), the dove, anchor, ship (fig. 2), palm branch, &c.; some with the portrait and name of Christ, or the images of the apostles or saints; and others with simple religious phrases, among the most common of which was VIVAS IN DEO or

FIG. 3.

SPES IN DEO. Rings to be used as seal rings alone were fitted with a plate of metal, which usually bore the owner's name together with some sacred symbol. This often took the

form of the bottom of a sandal or of the human foot (fig. 3), an outgrowth probably of the ancient tradition which made this image the symbol of possession.

Among the rings found in the catacombs are some with a key, and some with both a key and a seal (fig. 4), the latter for both locking and sealing a casket. A ring was worn by the early Christian bishops, and the custom still prevails in the Roman church. At the consecration of a bishop, this ring, called the episcopal or pastoral ring, is blessed and put upon the fourth finger of

FIG. 4.

his right hand, as a sign of his alliance with the church. Pope Gregory IV., who was elected in 827, in his work *De Cultu Pontificum*, says the ring is not put on the left hand, because it would seem to give credence to the pagan notion that a vein ran directly from the fourth finger of the left hand to the heart; but on the more worthy right hand, which gives the holy benedictions. The episcopal ring is always of gold set with an unengraved precious stone, usually an amethyst, but sometimes a sapphire, ruby, emerald, or crystal. In 1875, in the course of excavations in the chapter house of Durham cathedral, England, sapphire rings were found in the coffins of the bishops Ralph Flambard, who occupied the see from 1099 to 1128, Geoffrey Rufus, who died in 1140, and William de Sancta Barbara, who died in 1152. The ring of a cardinal is set with a sapphire. The seal ring of the pope is of steel, and is in the keeping of the cardinal chamberlain or chancellor; since the 15th century it has been used for sealing the apostolic briefs. On the death of a pope his ring is broken, and a new one is made for his successor. In England it is customary for sergeants at law on being sworn in to present gold rings to the law officers, certain other officials, and those who come to the inauguration feast. In 1737 1,409 rings, of the value of £773, were given away on the occasion of the admission of 14 sergeants. Rings were also formerly given away at weddings. Edward Kelly, the famous alchemist of Queen Elizabeth's days, is said to have given away at the marriage of one of his maid servants gold wire rings to the value of £4,000. It was with a golden ring that the doge of Venice wedded the Adriatic on Ascension day, casting it into the waters with these words: "We espouse thee, O sea, as a token of our perpetual dominion over thee."—The wedding ring is supposed to be of Roman origin, and to have sprung from the ancient custom of using rings in making agreements, grants, &c. It was usually given at the betrothal as a pledge of the engagement, and its primitive form was

probably that of a seal or signet ring. In Germany it has been common for the wife to wear the betrothal ring after marriage, and the husband the wedding ring. Widows formerly wore the wedding ring on the thumb, as an emblem of widowhood. Betrothal rings were frequently exchanged in ancient times by lovers. Gimmel, jimmel, gimbal, or gimmon rings are twin (*gemelli*) or double rings, made of gold wire twined together; but sometimes three and four rings were thus joined. It is also believed that the Romans originated the custom of giving rings with mottoes or posies engraved on them to their lady loves. In the 14th and 15th centuries the posy was usually inscribed on the outside of the ring, but afterward on the inside. Among the most common posies on old rings are the following: "Let lyking laste;" "Let us share in joy and care;" "I like my choice;" "A faithful wife preserveth life;" "Love and live happy;" "United hearts death only parts;" "I'll win and wear you;" "In Christ and thee my comfort be;" "This and the giver are thine for ever;" "Knit in one by Christ alone;" "As God decreed, so we agreed." Sometimes stones are so arranged as to form a posy, the first letter of each being read like an acrostic, thus: L apis lazuli, O pal, V erde antique, E merald.—Many superstitions have been connected with wedding rings. The once prevalent notion that an artery or nerve extended from the ring finger to the heart is of very ancient origin, and is probably due to the Egyptians. It has been thought too that the wedding ring is possessed of curative powers, and some persons still believe that a sty on the eyelid will disappear after being rubbed with a gold ring. Other rings than wedding rings were also used to cure diseases; a gold ring was supposed to be efficacious against St. Anthony's fire, and one made of silver collected at the communion was good against convulsions and fits. They sometimes owed their virtue to the stones with which they were set: thus diamond was believed to be an antidote against all poisons; ruby changed its color if any evil was about to befall the wearer of it; sapphire and the bloodstone checked bleeding at the nose; amethyst was an antidote against drunkenness; coral hindered the delusions of the devil; topaz cured and prevented lunacy; and the toadstone was considered a sovereign remedy against many disorders. Rings were also believed to possess magical virtues and to be full of occult significance. Plato records that Gyges, king of Lydia, possessed a ring which rendered him invisible when the stone was turned inward. The same story is told of Midas, the mythical king of Phrygia. The Arabians have a book called *Salcuthat*, which treats of magic rings. Among them is mentioned Solomon's ring with which he sealed up refractory jinn in jars before they were cast into the sea. Magic rings were manufactured in great numbers in Athens, and

endowed with whatever charm the purchaser required. The Gnostics engraved ring gems with mystic symbols, names, monograms, and legends, which were supposed to have peculiar values; and in the early ages the names of Jesus, Mary, and Joseph on rings were deemed to be preservatives against the plague. Rings were sometimes made hollow to contain poison. Hannibal died of poison which he carried in his ring. The ring of Cæsar Borgia had a slide within which he is said to have carried the poison that he sometimes dropped into the wine of his guests; and it is said that his father Alexander VI. possessed a key ring which had a concealed poisoned needle within it, and which, when he desired to rid himself of a person, he gave him to unlock a casket.

RINGGOLD, a S. county of Iowa, bordering on Missouri, and intersected by Platte river and by the E. and W. forks of Grand river; area, 576 sq. m.; pop. in 1870, 5,691. The surface is undulating and the soil fertile. The chief productions in 1870 were 40,381 bushels of wheat, 340,735 of Indian corn, 79,159 of oats, 27,894 of potatoes, 52,856 lbs. of wool, 163,485 of butter, and 14,325 tons of hay. There were 2,612 horses, 2,306 milch cows, 4,112 other cattle, 14,219 sheep, and 8,764 swine. Capital, Mount Ayr.

RINGWORM. See EPIPHYTES, vol. vi., p. 689.

RIO ARRIBA, a N. W. county of New Mexico, bordering on Arizona, and intersected in the southeast by the Rio Grande; area, about 5,500 sq. m.; pop. in 1870, 9,294. The E. part is watered by tributaries of the Rio Grande, the W. part by affluents of the San Juan, and it is crossed by several mountain chains. The chief productions in 1870 were 5,249 bushels of wheat, 10,351 of Indian corn, and 19,663 lbs. of wool. There were 399 horses, 749 mules and asses, 547 milch cows, 1,532 working oxen, 1,573 other cattle, 40,772 sheep, and 256 swine. Capital, Los Luceros.

RIO BRAVO DEL NORTE. See RIO GRANDE DEL NORTE.

RIO DE JANEIRO. I. A province of Brazil, lying between lat. 20° 50' and 23° 25' S., and lon. 40° 50' and 44° 40' W., bounded N. by Espírito Santo, N. W. by Minas Geraes, S. W. by São Paulo, and E. and S. by the Atlantic; area, about 18,000 sq. m.; pop. in 1871, 1,050,000, of whom 306,000 were slaves. (These numbers, and some others, are according to the *Almanach de Gotha* for 1875 and other recent authorities, those in the article BRAZIL having been derived from earlier sources.) The surface of the province is mountainous, being traversed by the Serra dos Orgãos (the local name of the Serra do Mar), and bounded W. by the Serra Mantiquiera. In the latter chain, about 5 m. from the N. W. corner of the province, is Itatiaiossú, the highest peak in Brazil (10,300 ft.) Many isolated hills rise from the plains, which are low and marshy. The only important river, the Parahyba do Sul, rises near Paraty, and, after a circuitous and

precipitous course of 400 m. between the two mountain chains (partly through the province of São Paulo), empties near the N. limit of Rio de Janeiro; it is navigable for only 50 m. from its mouth. Numerous salt lakes border the coast, and in the interior are extensive sheets of fresh water. There are many islands on the coast, the largest of which are Ilha Grande and Marambaya. The principal ports are Angra dos Reis, São João, Mangaratiba, Frio, Macahé, and Rio de Janeiro. The last, the only one of importance, is in the bay of the same name, and is one of the best in the world. It is an irregular basin penetrating inland 15 m., with a breadth varying from 2 to 9 m. The entrance, only 1,700 yards in width, is between steep hills, the eastern about 1,000 ft., the western 1,270 ft. in height. The latter is a conical isolated mass of gneiss, called Pão de Assucar. At its base is a fort, and on its opposite side another, forming the salient points of a system of fortifications designed to be impregnable. Just within and nearly midway of the entrance is an isolated rock, also fortified. The basin soon widens, and the shores trending in deep curves form beautiful bays and coves. Many islands and islets are scattered over its surface, the largest of which are cultivated and many of them fortified. Numerous streams empty into the basin, freshening its waters and forming banks on which grow large oysters. The greatest depth of water is 150 ft., just within the entrance; thence northward it shoals gradually, and in the head of the basin there is only 6 or 8 ft. The tides, owing to local causes, are irregular. The climate of the province is agreeable and salubrious on the high lands, but warm and unhealthy on the low lands and near the sea. Vegetation is luxuriant, and crops are abundant. The forests contain varied and excellent timber, and almost all kinds of tropical and temperate plants are found. Coffee, sugar cane, cotton, mandioca, and tobacco are extensively cultivated; tea, rice, cacao, and potatoes moderately. Coffee is the great staple, and its cultivation is steadily increasing. Nearly all the vegetables of temperate climes may be raised. Every variety of tropical fruit abounds, and flowers of rare beauty and fragrance adorn the gardens and forests. Among the native animals are the ounce, tapir, wild hog, and monkey. There are immense herds of cattle. The forests swarm with birds of brilliant plumage, and there is a large variety of beetles, butterflies, and other insects, many of them of great beauty. Fish of many varieties are found in all the waters. There is gold in the Cantagallo region near Minas Geraes, and garnets and amethysts are found. Iron is abundant, but no mines are worked; and granite, a great variety of marble, and several kinds of clay suitable for earthenware and porcelain abound. The province is divided into 17 districts, which are subdivided into municipalities, and these into parishes. Primary education is obliga-

tory. The state provides 164 primary and 4 advanced schools, and there are about 200 private schools in the province. The largest city, Campos, on the right bank of the Parahyba, about 35 m. from the sea, is said to contain 40,000 inhabitants. Niteroy or Niteroy, the capital, contains 25,000 inhabitants, but owing to its situation near Rio de Janeiro it is practically a suburban town. Petropolis, in a valley of the Orgãos, contains the summer palace of the emperor and many villas. Railways are constructing throughout the province, but the "Dom Pedro II." is the only completed road of importance. The chief cities are connected by telegraph. The commerce of the province is absorbed by the city of Rio de Janeiro. **II.** A municipality (Município Neutro) enclosed by the province of the same name, bounded N. by the rivers Guandú-Minin and Mirity, W. by the Guandú, S. by the Atlantic, and E. by the bay of Rio de Janeiro, the islands therein forming a part; extreme length from E. to W. 36 m., extreme breadth 24 m.; area, about 540 sq. m.; pop. in 1872, 274,972, of whom 48,939 were slaves. There are several groups of mountains within its limits, among the highest peaks of which are Tijuca, 3,447 ft., Gavia, 2,575 ft., and Corcovado, 2,272 ft. These, viewed from the sea, present a remarkable outline known as the "sleeping giant." Large boulders are scattered everywhere. In the plains and valleys are lakes of considerable size, only a few feet above the sea level, and there are numerous small streams and torrents, and many mineral springs. The coast is bordered with islands. Agricultural industry is devoted chiefly to the cultivation of fruit, vegetables, cereals, and grass to supply the markets of Rio de Janeiro; but there are several extensive coffee and sugar plantations, and large fields of mandioca. The municipality, which embraces the capital of the empire with a number of small communes, is governed directly by the executive and legislative authorities of the empire; it is divided into 19 parishes, and sends three deputies to the national assembly. There are 185 public and private schools for primary education, with an average daily attendance of nearly 15,000. **III.** The capital of Brazil, and the largest city of South America, situated in the Município Neutro, on the W. shore of the bay of Rio de Janeiro, in lat. 22° 54' S., lon. 43° 10' W.; pop. about 260,000. It is of irregular shape, being built chiefly on a narrow undulating plain extending for 6 m. along the bay. Several rocky hummocks, which rise from the low ground, give the city a picturesque appearance. The older streets are very narrow, and the older houses, generally of two stories and without architectural beauty, are badly arranged and poorly ventilated. The newer streets are wider, and the houses are of improved design, but wanting in modern conveniences. Many are painted in gaudy colors, some are ornamented with varie-

gated tiles, and others are covered with stucco; only a few are of granite or brick. The suburban dwellings are usually surrounded with gardens. The business streets are paved with cobblestones, and the others macadamized. Extensive sewers, of the aggregate length of 75 m., have recently been constructed throughout the city. At their three outlets attempts are made to disinfect and filter the sewage before it passes into the bay. Water is brought from Mt. Corcovado by means of an aqueduct which is more than 100 years old. It is 12 m. long, and crosses a valley 90 ft. deep and 740 ft. wide, upon two tiers of arches, one above the other. The water is distributed throughout the city to fountains, from which it is drawn for use. The supply is insufficient for the increasing demand. The streets, especially those of the suburbs, are lighted better than those of any other city in the world. The principal public edifices are the chamber of deputies and city palace of the emperor, in one spacious unattractive building fronting Palace square; the imperial chapel, of no architectural merit and unadorned, on the same square; the exchange, a low building divided into stalls which are rented to brokers, and containing a good reading room; the post office, unworthy of the business transacted through it; the custom house, perhaps the finest structure in the city; and the marine arsenal, also a fine building, at the end of the rua Direita, in which are all the preceding. The rua Ouvidor, leading out of this, is the principal street of Rio de Janeiro; from it leads the largo do São Francisco, on one side of which is the church of the same name and on the other the military academy. A narrow street leads thence into the largo do Rocio, in which is the theatre of São Pedro d'Alcantara. In the middle of this square is an equestrian statue of Dom Pedro I., the pedestal of which is ornamented with Indian figures emblematic of the great rivers of Brazil. The Campo Santa Anna, the largest square of the city, is unadorned and filthy; on one side of it is the senate, on another are military barracks and the offices of the minister of war, on a third those of the minister of commerce, and on the fourth the Italian opera house and a museum. Among the remaining public buildings are the hospital of Misericórdia, the mint, the academy of fine arts, the observatory, and the palace of São Christovão. Among the charitable institutions are several hospitals for natives, one for Portuguese, one for English, and others for French and Spaniards. The educational institutions are a national college, a military and engineering school, a naval academy, a commercial school, a school of medicine and surgery, a geographical and historical institute, a polytechnic and an agricultural school, several night schools for adults, and many other schools. The city contains 30 churches and chapels, and six convents and monasteries. Besides an Anglican chapel there are several

congregations of other Protestant denominations, composed chiefly of foreigners, the natives being nearly all Roman Catholics. The hotels, with one exception, furnish wretched accommodations. There are several libraries, only one of which, the imperial, contains books in different languages, the others being small and purely local. The imperial library, formerly the royal library of Portugal, brought from Lisbon by the emigrating royal family, has now upward of 100,000 volumes. Among other treasures it possesses the only complete series of Dürer's woodcuts of the "Passion of Christ." There are a government printing establishment and about 50 private publishing and printing houses; 70 native periodicals of little merit, a well conducted English daily newspaper, and a French and a German daily. There is one large market, plentifully supplied with great varieties of fish, poultry, fruit, and vegetables, but deficient in good meat and game. Of the two public gardens, the Passeio Publico is within the city, and the botanical just beyond its limits. Several lines of street railway traverse the city and its suburbs; omnibuses run to all the neighboring villages; two lines of steam ferry boats cross the bay; the Dom Pedro railway connects with the Parahyba river; and a steamer runs to the terminus of the Petropolis railway at the head of the bay. Steam communication with the seaports of the empire is frequent, European steamships arrive and depart almost daily, and there is telegraphic connection with Europe. A sea wall is now (1875) under construction along the water front of the city, beside which the largest vessels may lie. On the N. side of the Ilha das Cobras, off the N. E. extremity of the city, is a dry dock excavated from the solid rock, capable of admitting a vessel 280 ft. long and of 28 ft. draught; and a much larger one is in course of construction near it. There are numerous ship yards, and factories for the manufacture of cotton, tobacco, paper, soap, glass, and carriages, but none of the factories are very extensive. The climate is damp and unhealthy, and the city is seldom free from yellow fever, but this rarely assumes a malignant form. Diseases of the respiratory organs are very common. The mean annual temperature is 82° F.; the mean annual rainfall, 42.5 in. —The trade of Rio de Janeiro is hampered by the national export tax, which averages 13 per cent. on all articles of home production. The exports for the fiscal year 1872-'3 were valued at \$52,643,275, as follows: coffee, \$48,048,725; gold in bars and dust, \$2,108,462; diamonds, \$587,424; tobacco, \$521,990; hides, \$484,080; cotton, \$408,480; timber, \$275,165; sugar, \$133,559; rum, \$68,784; horse hair, India rubber, and wool, \$6,606. The United States takes about 58 per cent. of the coffee and half of the timber (fancy woods); Great Britain takes about half of the remaining exports; the residue is chiefly sent to France and Germany. The imports are very varied;

the value for the fiscal year 1872-'73 was \$36,511,450; more than one half are from Great Britain, about one fourth from France, the remainder chiefly from the Plata, Germany, and Portugal. Flour, kerosene oil, lumber, lard, rosin, and turpentine are almost the only articles received from the United States, the value of which in 1873 was \$2,415,000. The customs receipts of the port for the two financial years 1870-'72 were \$27,648,429. The import tax ranges from 40 to 50 per cent. The arrivals from foreign ports during the year 1873 were 4,431 vessels, of 2,639,362 tons; the departures 3,358, of 2,807,299 tons. The arrivals from Brazilian ports were 6,421 vessels, of 1,051,928 tons; departures, 7,203, of 1,345,648 tons. The total movement of shipping for 1873 was 7,844,237 tons. The trade of the port increases slowly, owing to exorbitant charges and unnecessary delay, which greatly diminish legitimate profits.—Although the bay of Rio de Janeiro was undoubtedly visited soon after the discovery of Brazil, and as early as 1502, it remained without name until Juan Diaz de Solis entered it on Jan. 1, 1516; thinking it the entrance to a river, he named it Rio de Janeiro (river of January). The first settlement was in 1531, but it was abandoned at the end of four months. The province having been conferred by John III. of Portugal as a gift on Martim Affonso de Souza, a small fort was built and a settlement formed near the entrance by him in 1552. This was neglected and appears to have been abandoned, for some French Huguenots under the command of Admiral Villegagnon formed the first permanent settlement in 1555, and erected a fort on the islet which now bears the name of their leader. The French were well received by the Indians, the Tamoyes, who were at enmity with the Portuguese; they carried on a lucrative trade with them, and named the colony Henriville, and the adjacent country Antarctic France. John III. ordered their expulsion, which was accomplished in 1565 by the governor of Bahia, who in 1567 founded another Portuguese colony near the present site of the Misericordia hospital, naming it São Sebastião. The history of the first century of the colony is replete with wars of extermination against the Indians, civil dissension among the colonists, and cruelty, oppression, and assassination. In 1710 the French made an unsuccessful attempt to take possession of the bay; their commander was taken prisoner and assassinated. The attempt was renewed in 1711 with success, but the commander, Duguay-Trouin, accepted a ransom and abandoned the bay. In spite of mismanagement and difficulty, the colony as well as the whole province prospered; and in 1763 Rio de Janeiro was made the capital of the viceroyalty. In the beginning of 1808 the royal family of Portugal came to Brazil on account of the occupation of the mother country by the French; their presence gave an impetus to the growth

of the city, which has ever since remained the first in commercial importance in Brazil. After the return of King John VI. to Portugal (1821) the Brazilians declared their independence and established an empire, with Dom Pedro I., the son of the king of Portugal, as emperor (1822). Thenceforward the history of the city is that of the empire. The capital of the province was transferred to Nictheroy and the municipality of Rio de Janeiro created in 1834.

RIO DE LA PLATA. See PLATA, RIO DE LA.

RIO GRANDE, a S. W. county of Colorado, formed since the census of 1870, intersected by the Rio Grande; area, 1,200 sq. m. The surface is mountainous, the San Juan being the principal range. There are valuable gold mines. Capital, Del Norte.

RIO GRANDE, or **Guahey,** a river of Bolivia, which rises in the S. declivity of the mountains near Cochabamba, and flows in a S. E. direction through the plains of the province to lon. 62° W. Here it bends abruptly N., and after a semicircular sweep round the eastern base of the Sucre mountain chain, holds a N. W. course to its junction with the Mamoré, S. of Trinidad, about lat. 15° S. Exclusive of its numerous sinuosities, it has a total length of about 700 m., the lower half being easily navigable by small steamers. Almost its entire course is through a densely wooded country. Among its affluents, most of which are from the west, is the Flores, a stream of considerable magnitude.

RIO GRANDE DEL NORTE, or **Rio Bravo del Norte,** commonly called simply the Rio Grande, a river of North America, rising in the S. W. part of Colorado, between the La Plata and San Juan mountain ranges. It flows E. for about 150 m., then bends abruptly S., entering New Mexico between the Sierra Madre and the main chain of the Rocky mountains, and flows through that territory to the Mexican border; thence it pursues a general S. E. course, separating Texas from Mexico, to the gulf of Mexico. Its entire length is estimated at 1,800 m. The upper part of its course is obstructed by rocky ledges and cataracts, and the lower part by sand banks and numerous wooded islands; but small steamers have ascended to Kingsbury's rapids, about 450 m. from the sea. The Rio Grande is subject to periodical floods, which commence in April, are at their greatest height in the beginning of May, and fall toward the end of June. For the greater part of the year it is fordable almost everywhere above the influence of the tide. The only important tributary is the Rio Pecos, which rises on the E. slope of the Rocky mountains, in N. E. New Mexico, flows S. through the E. part of the territory to the Texas border, and thence S. E. to the Rio Grande, which it enters about 500 m. above the gulf. Its entire length is estimated at 700 m. At certain seasons its bed becomes dry. Both the Rio Grande and the Pecos flow for the most part through an arid

region; but their valleys, which are generally from 1 to 4 m. wide, that of the Rio Grande expanding in places to 10 or 15 m., are productive when irrigated. The principal towns on the Rio Grande are Brownsville, Texas, about 35 m. from its mouth, and Matamoros, Mexico, opposite Brownsville.

RIO GRANDE DO NORTE, a maritime province of Brazil, bounded N. and E. by the Atlantic, S. by Parahyba, and W. by Ceará; area about 18,000 sq. m.; pop. in 1871, about 230,000, of whom about 13,500 were slaves. The coast is bordered by a chain of dangerous reefs and shoals, and the only good port is that of Natal, an irregular bay commonly called Rio Grande. Two watersheds running N. and S. divide the province into three almost equal parts, and give rise to many streams. The only important river is the Piranhas, which rises in Parahyba, passes through the middle of the province, and empties through five mouths, forming a large delta. It is navigable for 25 m., as far as the town of Assú, on the left bank. The Apody, passing through the western part, is navigable by canoes. Branches of the Borborema mountains extend into the province. The surface is sandy near the sea, and arid in the interior, except on the high lands and bordering the rivers, where there are extensive pastures and some forests. Gold, silver, and iron are found in small quantities, amianthus, limestone, crystals, and salt exist, and sulphur is met with. Good timber is abundant; gums, resins, balsams, Brazil wood, medicinal roots, wild honey, cochineal, and wax are among the natural productions. The carnahuba palm is extensively cultivated for a great variety of uses. Many tropical fruits abound; sugar, cotton, mandiocca, rice, beans, and tobacco are cultivated. The native animals are few, the reptiles numerous, many of them venomous. Large herds of cattle are raised. Sea salt is extensively extracted along the N. coast. The climate is very warm, dry, and unhealthy, severe droughts being frequent in the interior. The province is divided into eight districts. There are 62 public primary schools (41 for boys, 21 for girls), with an average daily attendance of 2,622, five secondary schools, and three private schools. The foreign exports of the province in 1873 were: cotton, \$385,344; sugar, \$165,552; hides, \$13,324; timber, \$135. The chief towns are Natal, the capital, Imperatriz, Assú, and Macaú.

RIO GRANDE DO SUL. See **SÃO PEDRO DO SUL**.

RIJOA, La. I. A W. province of the Argentine Republic, bounded N. and N. E. by Catamarca, E. by Cordova, S. by San Luis, S. W. by San Juan, and W. by Chili, from which it is separated by the Andes; area, 35,000 sq. m.; pop. in 1869, 48,493. Besides the Andes, the province is traversed in a generally N. and S. direction by the Jagüé, Famatina, and Velasco or Rioja ranges, the second containing the Nevado peak, 17,050 ft. above the sea. Be-

tween these chains are vast plateaus and valleys. The only important river is the Bermejo, descending from the Andes in the northwest, and draining the valley of Jagüé. Gold, silver, copper, iron, tin, and quartz occur extensively in the Famatina chain, precious stones in that of Velasco, and nickel, lead, antimony, carbonate of soda, salt, nitrate of potash, and nitrate of soda elsewhere. There are now (1875) in operation two gold, seven silver, and two copper mines. Maize, wheat, cotton, olives, grapes, and various other fruits are extensively cultivated; and timber, gums, honey, wax, and cochineal and other dyes are very abundant. Cattle rearing is one of the chief occupations. The manufactures comprise leather, cotton and woollen fabrics, laces, rum, cordials, and preserved fruits, all of which, with vicuña, guanaco, and puma skins, are largely exported. In 1869 there were 3,000 children attending school. The province is divided into the departments of La Rioja, Arauco, Famatina, Vinchina, Guandacol, Independencia, Costa Alta, San Martin, and Belgrano. **II.** A city, capital of the province, near the E. base of the Rioja mountains, 650 m. N. W. of Buenos Ayres; pop. in 1869, 4,489. It is situated in a vast plain, and has good streets and houses, with a parish church and three churches attached to convents. The surrounding country is remarkably fertile, and wheat and the vine are extensively cultivated. La Rioja was founded in 1591.

RIOM, a city of Auvergne, France, in the department of Puy-de-Dôme, near the left bank of the Ambère, 8 m. N. of Clermont-Ferrand; pop. in 1872, 10,770. It contains several handsome public edifices and the ruins of the ancient ducal palace. It has a college, an insane asylum, and a monument to Desaix, who was born near this town. The chief manufactures are linen, distilled spirits, and articles of wax. There is trade in grain, wine, hemp, leather, preserved fruits, and oil. In the 14th century Riom was the capital of the duchy of Auvergne.

RION. See **PHASIS**.

RIO NEGRO. I. A river of South America, an affluent of the Amazon, which rises in the state of Cundinamarca, United States of Colombia. Above the Cassiquiare it is called the Guainia, and a portion of its lower part is known as the Paraná Pishuna. After flowing E. about 200 m. from its source, it turns S. to lat. 2° N., where it is joined by the Cassiquiare, whose mouth is 600 yards wide, and which connects it with Orinoco. (See **CASSIQUIARE**.) About 50 m. below this it enters Brazil, and at the equator is joined by the Uaupes or Ucayari, which rises in the same hills as the Negro, but pursues a widely divergent course. After the junction the Negro descends over a series of rapids to São Gabriel, about 600 m. from its mouth at Manaos, and then becomes navigable, with a current of 3 or 4 m. an hour, flowing E. about 250 m. and receiving many

tributaries. About lon. 63° W. it receives the Rio Branco, after which it turns S. E., widens in some parts to 12 or 15 m., and becomes deep and sluggish, its waters sometimes flowing backward during the annual rise of the Amazon. Its extreme length is about 1,200 m. Steamers ascend to São Gabriel. The Negro was discovered by Favella in 1637, and soon after the Portuguese founded a settlement near the present site of Manaos. II. A river of South America, forming the boundary between the Argentine Republic and Patagonia. It rises between lat. 38° and 39° S., on the E. slope of the Chilian Andes, descending in four streams which unite and flow southward to lat. 40° 30', where it turns N. E. and flows over a series of rapids to about lon. 69° W. Here it receives the Neuquen from the north, after which it flows E. to lon. 66°, where it forms two islands, Rosas and Cholechel, the latter, which is 210 m. from the sea, being 27 m. long by 3 m. broad. It then pursues a general S. E. course to its mouth in lat. 41° 2' S., lon. 62° 45' W. Navigation to Cholechel island is always unimpeded. The lands along the river are well adapted to grazing and agriculture, and many kinds of valuable timber abound. Carmen de Patagones, a flourishing town of 6,000 inhabitants, is situated on both banks about 20 m. from the sea. The river banks near this place are thickly settled by Scotch and English farmers; the most distant settlement is about 100 m. from the sea. The value of the exports in 1873 was \$430,000. The Negro was first explored by Villarmo, who after encountering great difficulties reached the base of the Andes. In 1873 the Argentine government sent up an exploring party in a steamer, but after many mishaps the expedition was abandoned.

RIOT (Norman law Lat. *riota*, *riotum*; Fr. *riotte*, a brawl), in law, a tumultuous disturbance of the peace by three persons or more, who have assembled together of their own authority, for the purpose of assisting one another in the execution of some private enterprise, and in resisting any one who shall interfere with or oppose their proceedings, and afterward actually carrying out that purpose in a violent and turbulent manner to the terror of the people. It is wholly immaterial whether the act intended is lawful or unlawful; for it is not the act itself, but the manner in which it is done, which creates this particular offence. Two persons alone may be guilty of a conspiracy, but it requires three to make a riot; and where three persons were indicted for a riot, and the jury found only one of them guilty, it was held that this verdict was void because one alone could not make a riot. Women may be punished as rioters, but infants under 14 years of age cannot. The object of assembling is commonly a private quarrel or wrong; for the proceedings of a riotous assembly to redress public grievances or resist the officers of the king or state may amount to overt acts of

high treason, by levying war against the sovereign. In the latter case, the indictment generally charges that the defendants were armed and arrayed in a warlike manner, and, where the case admits it, with swords, drums, colors, and the like. But the question of riot or treason does not turn singly on any of these circumstances; the true criterion is: With what intent did the parties assemble—whether for a private and particular, or a public and general purpose? Numbers may supply the want of military arms and discipline, as experience has often shown, and such was the opinion of five of the judges in the weavers' case in 1675. In this case the weavers in and about London riotously assembled to destroy certain looms and machinery which had enabled those of their trade who used them to undersell the rest; and the defendants were indicted for treason, but were finally only proceeded against for a riot; the remainder of the court holding that their proceedings did not amount to a levying of war, as the motive was a mere private quarrel between different parties of the same trade, and related to no public or general object. On the trial of Lord George Gordon, the leader and instigator of the celebrated "no popery riots" in London in 1781, it was the unanimous opinion of the king's bench that an attempt by intimidation and violence to force the repeal of a law was a levying of war against the king. So, too, in the case of Demaree and Purchase, indicted severally in 1719, "for that they with a great multitude of people, to the number of 500, armed and arrayed in warlike manner, &c., did traitorously levy war, &c.," it appeared that the rabble, with cries of "Down with the Presbyterians," "Down with the meeting houses," &c., undertook by force and violence to carry their threats into execution, and actually did destroy a great deal of property, and resisted the officers sent to disperse them; and the judges agreed that this was a declaration against the "act of toleration," and an attempt to render it ineffectual by numbers and open force, and amounted to high treason. In every riot there must be such circumstances of actual force and violence, or an apparent tendency thereto, as will naturally strike terror into the people; though it is not necessary that actual force or violence should have been committed. The violence and tumult must also be premeditated; for if they arise accidentally from some cause not likely to produce them, it is but an affray. Thus, if several are assembled together for a lawful purpose and a quarrel happens among themselves, it is not a riot, but only a sudden affray, and none in the assembly are guilty but those who actually participate. But even though the persons assemble in the first instance for a lawful purpose and with peaceable intent, yet they may afterward be guilty of a riot. For instance, if a dispute arise among them, and they form themselves into parties or factions, with promises of mutual assistance, and then make an

affray, it is a riot; for the fact of forming such factions or parties and then acting with a definite and unlawful intention is constructive evidence of premeditation. If three or more persons, lawfully assembled, quarrel among themselves, and the party falls upon one or more of their own number, this is a simple affray; but if they attack a stranger, the very moment the quarrel begins it becomes an unlawful assemblage, and it is a riot in all those who join the affray, but only in them. So a person seeing a riot and joining therein becomes a rioter himself, though he did not go there premeditating the act, and is liable as a principal with the rest. The inciting persons to assemble in a riotous manner is also indictable. The law will not allow individuals to seek redress for private grievances by disturbing the public peace, though in some cases the justice of the quarrel in which they are engaged may be a great mitigation of the offence. —By the common law, riots were punished by fine and imprisonment, and if enormous by the pillory. But these penalties being found insufficient, statutory provisions were early made for their suppression. The first English statute enacted for this purpose was 34 Edward III., c. 1, E. II., which gave justices of the peace very extensive authority in such cases, and visited the offence with severe punishment. The statute 1 George I., commonly called the "riot act," made it a capital felony for persons riotously assembled to the number of 12 or more to continue so assembled for one hour after proclamation by a justice of the peace requiring them to disperse; thus leaving the offence, if committed by more than 3 and fewer than 12 persons, punishable by fine and imprisonment only, but if by 12 or more by death. Subsequent statutes made other specific offences felonious, such as riotously demolishing any church or chapel, or any house or other building, or any machinery or manufactory, or forcibly obstructing the export of corn from any part of the kingdom. Principals in the second degree and accessories before the fact were also punishable as felons. In the United States the statutory provisions respecting riots follow in a great measure those of England, but are milder in their punishments and more qualified in their application.

RIPARIAN (Lat. *ripa*, the bank of a river), in law, a term relating to the rights and privileges of persons who own lands lying upon or bounded by streams or rivers. At the common law all bays and arms of the sea, and all rivers wherein the tide ebbed and flowed, were considered navigable, or public highways; and all rivers, irrespective of size, where the tide did not ebb and flow, were unnavigable. The owner of land lying upon an unnavigable stream (in the common law sense) owns the bed of such stream to its centre, or thread; and the grant of a piece of land bounded by a river will carry the exclusive right and title of the grantee to the middle of the river, unless

the grant certainly expresses the intention of the grantor to convey only to the bank or margin. If a person owns the land lying on both sides of the river, he also owns the whole river as far as his land extends along it; and the owner in fee of land lying under an unnavigable river, whether he owns the whole bed or only to the centre on one side, may sell and convey such land separate from the upland to which it is attached. Where a river is actually navigable for boats and rafts, the public have an easement in the water for this purpose, and are entitled to a right of passage up and down, which the riparian proprietors cannot interfere with or prevent; and all obstructions or impediments to the free use of the river in this manner are public nuisances, which the public may lawfully abate. The owners hold the land under the water subject to the public right of passage over it. The proprietors of adjoining banks are entitled to use the water of the river, and the land under it, as regards the public, in any manner or for any purpose whatever, not inconsistent with this easement; and neither the state nor any private individual has a right to alter the course or character of the stream, or to render it by any means less useful to the owner of the soil. —When a piece of land in a conveyance lies upon and is bounded by a navigable pond of water, it is generally held that the grant only extends to the margin of the pond, and the grantee acquires no right to the soil beneath it. So riparian owners on technically navigable rivers, that is, on rivers in which the tide flows, are not entitled, as a matter of right, to the soil under the water in front of their uplands, because it belongs to the state. The land covered by navigable ponds and lakes also belongs to the state when these are not private property, but a grant of the bed of such a pond or lake could only be made to the owner of the adjoining shore. —If the water running between the lands of separate owners gains gradually and imperceptibly upon one side or the other, the title of each continues as before to the middle of the stream regardless of the change. But if the change takes place suddenly and visibly, the ownership remains unchanged, and the boundary line continues as previous to the alteration, at what then was the middle of the stream. If therefore the river should suddenly and entirely forsake its natural channel, and make for itself a new one in the lands of the proprietor on one side, he would thereby become the exclusive owner of the soil under the whole river so far as it was enclosed in his land. If soil be formed by alluvium or the washing up of earth out of the river, by slow and imperceptible accretion, or by the dereliction of waters which have gradually receded and left the land beneath them bare and dry, it belongs to the owner of the adjoining land. Islands formed in the same manner are subject to the same rule. If they are formed near the shore, they belong to the person who owns the land on

that side of the stream to which they are nearest; if they are formed in the middle of the stream on both sides of the dividing line or centre, they belong to the proprietors on both sides in proportion to the extent which may lie on their respective sides of the line. Lands and islands formed out of the sea, or in navigable, *i. e.*, tide rivers, belong to the sovereign or state, and not to the proprietors of the adjoining shore. By the common law the seashore, being that part between high and low water mark where the tide ebbs and flows, belonged to the sovereign or state, and was common to all the public, the possession of the adjoining proprietors extending only to high-water mark; but in this respect the common law has been changed in Massachusetts and Maine, as to owners on bays and arms of the sea, by the colony ordinance of 1641 and the usage arising therefrom, and the proprietorship goes to low-water mark, subject to the public easement, and not exceeding 100 rods below high-water mark. And now, in other states which lie on tide waters, the owner of land has some right to use it as far as low water, for the purpose of putting a wharf or similar building there.—The common law definition of a navigable river, being one where the tide ebbs and flows, has been considered and judicially adjudged to be inapplicable to the great rivers of Pennsylvania, Alabama, and other states. These rivers are declared to be navigable, and the boundaries of adjacent lands extend not to the middle of the stream, but only to low-water mark. But this question, where not particularly regulated in the several states by statute or judicial decisions, is still somewhat unsettled; and even where navigable waters are declared to be common highways, and as such for ever free to the public, it does not appear that the common law principle, that he who owns the land on both sides owns the entire river, and he who owns the land on one side only owns to the middle of the river, in both cases subject only to the easement of navigation, is thereby abolished.—While every riparian proprietor has an equal right to the free use of the water which passes his land, as it is accustomed to flow, without any diminution or alteration as to quantity or quality, he has no exclusive property in the water itself, but a simple usufruct while it passes along; and he cannot appropriate it to his exclusive use, or divert it from its natural channel, without the consent of the adjoining proprietors, who have an equal right to its use with himself. If he does divert it on his own premises, he must return it to its ordinary course when it leaves his estate. He may use it to irrigate his lands or to water his cattle, or he may use the whole force of it in any reasonable manner he chooses, so long as such use does not interfere with the rights of his neighbors. But he cannot use it to the prejudice of any adjoining proprietor, unless he has a prior right to divert it, or a right by grant or by prescription (which sup-

poses a grant) to some exclusive enjoyment of it. Whether, without such right, his use is reasonable, depends upon the circumstances of each case. The natural title which riparian owners thus have to the reasonable use of the waters may be restricted, altered, or enlarged by such grants or prescriptions; otherwise streams of running water could never be effectually applied either to agricultural or manufacturing purposes. Twenty years' exclusive occupation and use of water in any particular manner raises the presumption of a grant for that purpose from the adjoining proprietors; and owners whose land lies above or below must take the stream subject to such adverse right. But nothing short of an express grant, or the use and enjoyment of the water so diverted or obstructed, or materially changed in its course and character, for a sufficient length of time to raise the legal prescription of a grant, will justify the owner as against any other owner to whom such alterations may prove injurious.—By the common law the proprietor of land lying upon an unnavigable river possesses the exclusive right to fish therein, as far as the middle of the stream; and if he owns both sides he has exclusive right, for fishing purposes, to the whole river, as far as his land extends, subject only to the rights of the public in the same as a highway for navigation. But this right is qualified by the same general rule which regulates his other riparian rights; it must be so used as not to injure or interfere with the rights and privileges of others. Therefore he cannot erect dams, weirs, or other obstructions for the purpose of preventing the ascent or passage of fish. Such impediments were regarded by the common law as a nuisance, and in Massachusetts the party offending in this manner is subject to a penalty provided by statute. The common law right of fishing may be controlled or modified by the municipal law of the land, and in many of the states it is regulated by statute provisions. On navigable rivers and tide waters, however, the adjoining proprietors do not possess this exclusive right of fishing opposite to their own lands; it is a public and common privilege in which every one is equally entitled to share. But this public right of fishing in the water does not extend to permitting a stranger to pass over the land of another in order to reach the water. Neither are persons claiming and enjoying this common right entitled to draw the seine, or to fish, or build fishing huts, or dry their nets, upon the land of the adjoining owner, or upon islands which are private property; this privilege belongs exclusively to the owner of the soil. The civil law declared that the right of fishing was common in rivers, as well as in the sea, and gave the use of the adjoining banks for this purpose to the public. This principle is acknowledged where the civil law prevails, and has been adopted by some of the states in regard to their large navigable rivers, but it is unknown to the common law.—

A question which has been much discussed and variously regulated by different nations is that relating to the public right to a foot or tow path along the banks of navigable rivers, and the use of the banks for the assistance or convenience of navigation. The civil law allowed such a right, and held that all persons had the same right to bring their vessels to land and fasten ropes to the banks of the river that they had to navigate the river itself. The same doctrine is held in Louisiana, where it has been decided that, though the banks of navigable rivers are the property of those who own the adjoining lands, yet they are so far subject to the public use, that vessels may make fast to the shore and to the trees upon it, and may unload and deposit their goods there. The rule in Illinois, Tennessee, and Missouri seems to be substantially the same. In New York, Delaware, Pennsylvania, Michigan, Mississippi, Indiana, and perhaps some other states, it has been adjudged that the public have no such right as against the will of the owner. The common law, according to Bracton, was anciently the same as the civil law, but the point remained unsettled till 1789, when it was decided that there was not any right at common law for the public to tow on the banks of navigable rivers.—Another unsettled question in the United States is that respecting the right of ferriage which attaches to riparian ownership. This matter is generally regulated by statute, and the state, by virtue of the law of eminent domain, claims the right to establish ferries wherever the legislature may consider them necessary for the public accommodation, regardless of the ownership of the soil, except as giving a claim for just compensation. But the statutes usually authorize the grant of the franchise by way of preference to the owners of the land on each side of the river where the ferry is established. It has been held that the riparian owner has not, as a matter of right, the privilege of keeping a ferry, and that it can only arise from a grant, actual or implied. This was probably the rule of the common law. But, in the United States, we should say that it is the prevailing rule that the right to a ferry attaches to the riparian proprietor; that it cannot be taken from him without compensation; that he may convey the soil excepting the right of ferriage, which then becomes an incorporeal hereditament, and may be granted in the same way as a rent; and the grantee will have a right to use the adjoining soil so far as may be necessary for ferry ways, but not otherwise.

RIPLEY. I. A S. E. county of Indiana, intersected by Laughery creek; area, about 450 sq. m.; pop. in 1870, 20,977. It has a generally level surface, and the soil is fertile. It is traversed by the Ohio and Mississippi and the Indiana, Cincinnati, and Lafayette railroads. The chief productions in 1870 were 204,995 bushels of wheat, 441,645 of Indian corn, 131,771 of oats, 84,189 of potatoes, 19,504 tons of hay,

5,104 lbs. of tobacco, 48,912 of wool, 380,911 of butter, 22,511 of hops, and 46,713 gallons of sorghum molasses. There were 6,439 horses, 6,127 milch cows, 7,860 other cattle, 18,358 sheep, and 18,554 swine; 4 manufactories of brick, 16 of carriages and wagons, 8 of saddlery and harness, 8 tanneries, 10 flour mills, and 21 saw mills. Capital, Versailles. II. A S. E. county of Missouri, bordering on Arkansas, intersected by Current river, and drained by numerous creeks; area, about 600 sq. m.; pop. in 1870, 3,175, of whom 10 were colored. It has a rough and hilly surface. The chief productions in 1870 were 17,725 bushels of wheat, 142,485 of Indian corn, 14,214 of oats, 4,105 lbs. of wool, and 41,961 of butter. There were 1,068 horses, 937 milch cows, 2,357 other cattle, 2,989 sheep, and 10,470 swine. Capital, Doniphan.

RIPLEY, George. See supplement.

RIPLEY, Henry Jones, an American clergyman, born in Boston, Mass., June 28, 1798, died at Newton Centre, May 21, 1875. He graduated at Harvard college in 1816, studied theology at Andover, was ordained in Boston in 1819, and became pastor of the North Newport Baptist church, in Liberty co., Ga. In 1826 he was appointed professor of Biblical literature and pastoral duties in the Newton theological institution, Mass.; in 1833, when the duties of the professorship were divided, he became professor of Biblical literature and interpretation, and afterward of sacred rhetoric and pastoral duties. He resigned in 1860. He published "Memoir of Rev. Thomas S. Winn" (Boston, 1824); "An Examination of Prof. Stuart's Essay on the Mode of Baptism" (1833); "Notes on the Four Gospels" (2 vols., 1837-'8); "Notes on the Acts of the Apostles" (1844); "Sacred Rhetoric, or Composition and Delivery of Sermons" (1849); "Notes on the Epistle to the Romans" (1857); "Exclusiveness of the Baptists" (1857); "Church Polity" (1867); and "Notes on Hebrews" (1868).

RIPLEY, Roswell Sabine, an American soldier, born in Ohio about 1823. He graduated at the military academy at West Point in 1843, and was appointed brevet second lieutenant in the artillery. He served during the war with Mexico, and was brevetted as captain and major for gallant conduct at Cerro Gordo and Chapultepec. He subsequently served in Florida, and in 1853 resigned his commission in the army, taking up his residence at Charleston. On the breaking out of the civil war he entered the confederate service, rose to the rank of brigadier general, and was wounded at Antietam. He published a "History of the War with Mexico" (2 vols. 8vo, New York, 1849).

RIPON, George Frederick Samuel Robinson, earl de Grey and marquis of, an English statesman, born in London, Oct. 24, 1827. He was a member of parliament from 1852 to 1859, and became prominent as a liberal under the name of Viscount Goderich. On the death of his father, the first earl of Ripon, Jan. 28, 1859, he took his seat in the house of lords,

and on Nov. 14 of the same year he inherited his uncle's title of earl de Grey. He was under secretary of state for war from June, 1859, to February, 1861, and again from July, 1861, to April, 1863, and secretary thenceforward till February, 1866; and he was connected with the India board from February to July, 1861, and from February to June, 1866. At the close of 1868 he became president of the council. In 1871 he went to Washington as chairman of the high joint commission which concluded the treaty of Washington in regard to the Alabama claims, and was for his services made marquis, June 23. In 1872 he was elected for the third time grand master of the freemasons in England, which post he resigned in 1874 on joining the Roman Catholic church.

RIPPLE GRASS. See PLANTAIN.

RISTORI, Adelaide, marchioness del Grillo, an Italian actress, born at Cividale in Friuli in 1821. Her parents were comedians, and brought her up for the stage. Previous to her marriage in 1847 with the marquis Capranica del Grillo she excelled chiefly in comedy. Subsequently she became celebrated in tragedy, especially as Myrrha, Francesca da Rimini, Pia dei Tolomei, Mary Stuart, and Queen Elizabeth. She first appeared in Paris in 1855, and in 1867 and 1875 she visited the United States.

RITCHIE, a N. W. county of West Virginia, intersected by Hughes river, a branch of the Little Kanawha; area, about 450 sq. m.; pop. in 1870, 9,055, of whom 63 were colored. It has a hilly surface, covered with forests, and the soil is fertile near the streams. It is traversed by the Parkersburg division of the Baltimore and Ohio railroad. The chief productions in 1870 were 25,510 bushels of wheat, 35,635 of rye, 146,235 of Indian corn, 40,033 of oats, 4,732 tons of hay, 9,907 lbs. of tobacco, 26,828 of wool, 116,094 of butter, and 29,257 gallons of sorghum molasses. There were 1,970 horses, 5,334 cattle, 11,607 sheep, and 4,617 swine. Capital, Harrisville.

RITCHIE, Anna Cora Mowatt. See MOWATT.

RITCHIE, Thomas, an American journalist, born at Tappahannock, Va., Nov. 5, 1778, died in Richmond, July 12, 1854. After teaching four years at Fredericksburg, he removed to Richmond in 1803, and in 1804 became editor of the Richmond "Examiner," the name of which he changed to "Enquirer." He continued its editor and proprietor for 40 years, exercising an unsurpassed influence over the politics of Virginia and the Union. In 1845 he relinquished the "Enquirer" to his sons, and removed to Washington, where he edited for four years the "Union," a journal established as the organ of President Polk's administration. He subsequently returned to Richmond, and spent his latter years in retirement.

RISES, Congregation of, the name of a committee of cardinals in the Roman Catholic church, established by Sixtus V., and originally composed of six cardinals, with a number of secretaries and consultors. The number of

members depends on the will of the reigning pope. In 1875 it comprised 17 cardinals, 25 consultors, and 11 officials, including secretary, promoters of the faith, and assessors, besides the papal masters of ceremonies. The matters exclusively within its cognizance are the liturgy, the rites of the administration of the sacraments, the rubrics of the missal and breviary, the ceremonial of the church in all public functions, and the proceedings in the beatification and canonization of saints. The congregation meets once a month at the residence of the prefect, who is always the senior cardinal of the board.

RITSON, Joseph, an English antiquary, born in Stockton, Oct. 2, 1752, died Sept. 23, 1803. He was a lawyer, but devoted himself chiefly to literary pursuits. His numerous writings are marked by great accuracy, honesty, and learning, and by their abusive spirit. His harshness led to controversies, in which he seems to have been constantly engaged until his death. An "Essay upon Abstinence from Animal Food as a Moral Duty" was fiercely attacked by the "Edinburgh Review" (April, 1803), in an article written by Sydney Smith and Lord Brougham. Ritson's chief works are: "Remarks Critical and Illustrative on the Text of the last Edition of Shakspeare" (1783), an attack upon Johnson and Steevens; "A Select Collection of English Songs" (3 vols. 8vo, 1783; 2d ed., 1813); "Ancient Songs from the time of King Henry III. to the Revolution" (1790; 2d ed., 1829); "The English Anthology" (3 vols., 1793-4); "A Collection of Scottish Songs, with the Original Music" (2 vols., 1794; new ed., 18mo, 1866); "Robin Hood, a Collection of all the Ancient Poems, Songs, and Ballads now extant relating to that Outlaw" (2 vols., 1795; 3d ed., 1858); "Ancient English Metrical Romances, with Dissertation and Glossary" (3 vols., 1802); "Bibliographia Poetica," an account of English poets from the 12th to the 16th century, never completed, but forming a treasury from which many others have drawn.—See "Letters of Joseph Ritson, Esq., with a Memoir," by Sir Harris Nicolas (2 vols., 1833).

RITTENHOUSE, David, an American mathematician, born at Germantown, Pa. (near which his great-grandfather, William Rittinghuysen, a Hollander, had established about 1690 the first paper mill in America), April 8, 1732, died in Philadelphia, June 26, 1796. During his youth he came into possession of the tools and mathematical books of a deceased uncle, made clocks without any instruction, and followed the occupation of clock making. He was commissioned by the proprietary government in 1763 to determine the initial portion of the boundary line since known as Mason and Dixon's; and although his instruments were all of his own construction, the official surveyors adopted his measurements. He was subsequently employed in determining the boundaries between New York, New Jersey, and

Pennsylvania, and other states. He calculated the transits of Venus of June 3, 1769, and Dec. 8, 1874, and made a successful observation of the former in his observatory at Norriton. In 1770 he removed to Philadelphia, and in 1775 was elected to the provincial legislature. He was a member of the convention called to form a state constitution, state treasurer from 1776 to 1789, and director of the United States mint from 1792 to 1795. In 1791 he succeeded Franklin as president of the American philosophical society, to whose "Transactions" he had contributed many papers, and in 1795 he was chosen a fellow of the royal society of London.—See his life by William Barton (8vo, Philadelphia, 1813), and by Prof. James Renwick in Sparks's "American Biography."

RITTER, Carl, a German geographer, born in Quedlinburg, Aug. 7, 1779, died in Berlin, Sept. 28, 1859. He completed his studies at Halle, and in 1798 became tutor in the Bethmann-Hollweg family at Frankfort, and accompanied his pupils to the academy of Geneva, and to various countries. He was professor of history at the gymnasium of Frankfort in 1819-'20, and subsequently of geography at the university and military academy of Berlin. He created the science of general comparative geography. His most celebrated work is *Die Erdkunde im Verhältnisse zur Natur und Geschichte des Menschen*. At first it appeared in two volumes (Berlin, 1817-'18), but in the second edition the first volume (1822 *et seq.*) relates exclusively to Africa, and 18 volumes (1832-'59) to Asia. W. L. Gage has translated some of Ritter's work into English, under the titles "Comparative Geography" (Edinburgh, 1865) and "The Comparative Geography of Palestine and the Sinaitic Peninsula" (4 vols., 1866). Ritter also published *Europa, ein geographisch-historisch-statistisches Gemälde* (2 vols., Frankfort, 1807); *Die Stupas* (Berlin, 1838); and *Einleitung und Abhandlungen zu einer mehr wissenschaftlichen Behandlung der Erdkunde* (1852). After his death were published his *Geschichte der Erdkunde und der Entdeckungen* (1861), *Allgemeine Erdkunde* (1862), and *Europa* (1863). Among his biographers are Kramer in German (Halle, 1864) and Gage in English (New York, 1867).

RITTER, Heinrich, a German philosopher, born in Zerbst in 1791, died in Göttingen, Feb. 3, 1869. He studied at the universities of Halle, Göttingen, and Berlin, and was professor successively at all of them, at Göttingen for the last 32 years of his life. He was an eclectic in philosophy. His principal work is *Geschichte der Philosophie* (12 vols., Hamburg, 1829-'53; the part relating to ancient philosophy translated into French by Tisset, 4 vols., Paris, 1836-'7, and into English by A. J. W. Morrison, 4 vols., Oxford, 1838-'46; additional French translation by Trullard, 2 vols., 1843-'4). Among his other writings are: *System der Logik und Metaphysik* (2 vols., Göttingen, 1856); *Die christliche Philosophie* (2 vols.,

1858-'9); and *Encyklopädie der philosophischen Wissenschaften* (3 vols., 1862-'4).

RITUALISM, the science of the rites embodied in a ritual or book of rites. The term is popularly, though inaccurately, applied to a movement in churches of the Anglican communion, the three successive periods of which have been called by its opponents "Puseyism," "Tractarianism," and "Ritualism;" but its adherents assert it to be a catholic revival. The principles of ritualism as described by the latter are three. They say, in the first place, that it rests on the declaration set forth in 1571 by the same convocation of Canterbury which first required subscription to the thirty-nine articles: "that preachers should in the first place be careful never to teach anything from the pulpit, to be religiously held and believed by the people, but what is agreeable to the doctrine of the Old and New Testaments, and collected out of that very doctrine by the catholic fathers and ancient bishops." This is held to establish the doctrinal identity of the church of England with the primitive church, and has led to elaborate commentaries by ritualistic writers on Holy Scripture, and to the reproduction of patristic teaching on all leading points of faith and practice. The apostolic episcopate and sacramental grace are specially insisted on; baptismal regeneration is strenuously asserted; and the holy eucharist has been made the central object of teaching and the highest act of worship. The frequency as well as the splendor of eucharistic celebrations has steadily increased, and a fasting reception has been encouraged by early celebrations. The real presence of Christ in that sacrament—a presence spiritual as opposed to carnal, objective as opposed to the idea that it is only in the heart of the believer, and supralocal as opposed to the notion that it is contained within and limited to the species of bread and wine—has been incessantly advocated, until eucharistic adoration is now openly taught and practised. The voluntary use of private confession and absolution, as a preparation for the reception of the holy communion, has also made considerable progress. The second great principle of the ritualists is thus stated in the 30th canon of the English church: "So far was it from the purpose of the church of England to forsake and reject the churches of Italy, France, Spain, Germany, or any such like churches, in all things which they held and practised, that, as the apology of the church of England confesseth, it doth with reverence retain those ceremonies which do neither endanger the church of God nor offend the minds of sober men; and only departed from them in those particular points wherein they were fallen both from themselves in their ancient integrity, and from the apostolical churches which were their first founders." This principle, it is alleged, establishes the fraternal readiness of the church of England for visible reunion with other branches of the apostolic church. The ritualists assert,

therefore, that they are willing to do any and everything lawful to approximate toward the continental churches, from which the Anglican communion is now severed. The third fundamental principle of ritualism is found in the ornaments rubric, which has stood in the English prayer book, almost unaltered, from the beginning of the English reformation: "The chancels shall remain as they have done in times past. And here it is to be noted, that such ornaments of the church and of the ministers thereof, at all times of their ministration, shall be retained and be in use as were in this church of England, by the authority of parliament, in the second year of the reign of King Edward the Sixth." By this law, it is thought, the chancels as well as the vestments and "ornaments of the church and of the ministers thereof" should be precisely the same now as they were before the reformation, no change in them having been made in the second year of Edward. In the case of *Liddell v. Westerton*, the judicial committee of the privy council interpreted the law to refer to the rubrics of Edward the Sixth's first book, which did not come into use till Whitsunday in the third year of his reign. That rubric, in the "Order for administering the Supper of the Lord and the Holy Communion, commonly called the Mass," reads as follows: "Upon the day and at the time appointed for the ministration of the holy communion, the priest that shall execute the holy ministry shall put upon him the vesture appointed for that ministration, that is to say, a white albe plain, with a vestment or cope. And where there be many priests or deacons, there so many shall be ready to help the priest in the ministration as shall be requisite; and shall have upon them likewise the vestures appointed for their ministry, that is to say, albes with tunicles." A further rubric of the same book orders: "Whensever the bishop shall celebrate the holy communion, or execute any other public office, he shall have upon him, besides his rochet, an albe and cope or vestment, and also his pastoral staff in his hand, or else borne by his chaplain." As, in the opinion of ritualists, the three leading principles of the so-called catholic revival thus bind together the present church of England with the primitive, the mediæval, and the continental churches, they profess to give prominence to everything which helps to make this union real, without violating their clear obligations as members of the church of England. There are six chief points depending more or less closely on the principles laid down: 1, the eastward position of the celebrant in the sacrament of the holy communion, with his back to the people; 2, the eucharistic vestments; 3, lights burning at the time of the celebration; 4, incense; 5, the mixed chalice, a little water being added to the wine; 6, unleavened (or wafer) bread. The opponents of these usages have attempted to proscribe them through prosecutions in the English ec-

clesiastical courts. In the case of *Liddell v. Westerton* (1867), it was decided "that the same dresses and the same utensils, or articles, which were used under the first prayer book of Edward the Sixth, may still be used;" which left the ritualists in possession of the field. Suits were subsequently instituted against Mr. Macconochie (1868) and Mr. Purchas (1870), the latter of which was not defended. All the six above mentioned usages and some others were condemned by the highest court of appeal. The advocates of ritualism protested against the decision, which in their view impaired the authority of the court, and parliament has since provided for the establishing of a different tribunal for the hearing of ecclesiastical appeals. One decision, condemning the eastward position, was protested against in writing by about 5,000 of the clergy of the established church. Of more importance than these cases was that of the Rev. W. J. E. Bennett, vicar of Frome, who published a sermon in which he taught "the real and actual presence of our Lord, under the form of bread and wine, upon the altars of our churches." He stated "the three great doctrines on which the Catholic church has to take her stand" to be: "1, the real objective presence of our blessed Lord in the eucharist; 2, the sacrifice offered by the priest; 3, the adoration due to the presence of our blessed Lord therein;" adding: "I am one of those who burn lighted candles at the altar in the daytime; who use incense at the holy sacrifice; who use the eucharistic vestments; who elevate the blessed sacrament; who myself adore, and teach the people to adore, Christ present in the sacrament, under the form of bread and wine; believing that under their veil is the sacred body and blood of my Lord and Saviour Jesus Christ." The court of arches, through Sir Robert Phillimore (who said that if he pronounced otherwise he "should be passing sentence, in his opinion, upon a long roll of illustrious divines"), having decided in Mr. Bennett's favor, his prosecutors appealed to the judicial committee of the privy council (1872), which, although manifesting a strong animus against Mr. Bennett and Sir Robert Phillimore, dismissed the appeal. Encouraged by this doctrinal victory, the English ritualists have announced their determination to persevere until they have recovered what they consider their rightful heritage as a true branch of the Catholic church, in accordance with the professed principles, canons, and rubrics of the reformed church of England, as illustrated by the facts of her history. While devoting close study to holy writ, they have investigated the questions of liturgies and ritual in all ages of the church, especially the reformation era, have taken the lead in hymnology, and have produced many manuals and catechisms for the promotion of personal devotion. They have encouraged the revival of religious orders, mainly for works of charity; and there are many communities

of women who under their rule have devoted themselves to life-long labor in hospitals and similar institutions, for the love of God and their neighbor. An evangelist brotherhood of preachers has also been formed, who devote themselves to the holding of missions in cities and towns. In this country there is more or less of sympathy with the English ritualistic movement, but with much less development of detail. The attempts made in the general conventions of 1863, 1871, and 1874 to legislate against various usages regarded as ritualistic, were all defeated. In 1874 a general canon was passed (by many considered to be unconstitutional), which was regarded as a nearly unanimous expression of opinion unfavorable to ritualistic extremes; but no occasion has arisen in any diocese for putting it in force.

RIVAROL, Antoine, a French author, born at Bagnols, Languedoc, June 26, 1753, died in Berlin, April 13, 1801. After preparing himself for the church he became a private tutor at Lyons. In 1777 he went to Paris, where he assumed after his mother the name of chevalier de Parcieux, and next that of Count Rivarol. He led a dissipated and adventurous life, and acquired celebrity as a wit, satirist, journalist, poet, and miscellaneous writer. He defended Louis XVI., who had given him a pension of 4,000 livres, and in 1792 fled to Brussels. He afterward went to London and Hamburg, and in 1800 to Berlin on a mission from the future Louis XVIII. His principal works are: *Discours sur l'universalité de la langue française* (1784); *Petit almanach de nos grands hommes* (1788); and *Vie politique de Lafayette* (1792). Chénédolle and Fayolle edited his works under the title *Esprit de Rivarol* (5 vols., 1808).—His wife, an English woman, wrote *Notice sur la vie et la mort de M. de Rivarol* (2 vols., Paris, 1802). See also *Rivarol, sa vie et ses ouvrages*, by M. de Lescure, accompanying a select edition of his works (1862).

RIVAS, Ángel de Saavedra, duke of, a Spanish poet, born in Cordova, March 1, 1791. After advocating constitutional government in the cortes, he was exiled from 1823 to 1834. In 1836 he became minister of the interior in the government of Isturiz, which was soon driven from power by the revolutionary movement of La Granja. He was again banished by Espartero in 1837, but returned with Queen Maria Christina in 1843, and was ambassador to Naples till 1848. In 1854 he belonged to the short-lived cabinet which was overthrown by O'Donnell. Next he was ambassador in Paris, and in 1864 he presided for some time over the council of state. His principal works include, besides tragedies and comedies, *Ensayos poéticos* (2 vols., Madrid, 1813); *Florinda*, an epic poem on the Moorish conquest (1824-'5); *Romances históricos* (2 vols., Paris, 1840-'41); *El Moro espósito*, an epic poem (2 vols., 1844); and *Historia de la sublevación de Nápoles* (2 vols., Madrid, 1848; French translation by D'Hervé de Saint-Denis, Paris, 1849).

RIVE-DE-GIER, a town of France, in the department of Loire, on the Gier, an affluent of the Rhône, 12 m. N. E. of St. Etienne; pop. in 1872, 13,946. It has blast furnaces and forges, and steam engines, steel, glass (chiefly bottles of fine quality), and ribbon are manufactured. Near it are silk mills, extensive coal fields, and the reservoir of the Givors canal.

RIVER HOG. See **WART HOG**.

RIVES, William Cabell, an American statesman, born in Nelson co., Va., May 4, 1793, died near Charlottesville, Va., April 26, 1868. He was educated at Hampden Sidney and William and Mary colleges, and studied law. In 1816 he was a member of the state constitutional convention; and from 1817 to 1819, and in 1822 of the state legislature. In 1823-'7 he was a representative in congress, and in 1829-'32 minister to France. He was elected United States senator in 1832, and resigned in 1834, but was reelected in 1835 and again in 1840, serving till 1845. He was again minister to France from 1849 to 1853. In 1861 he was a member of the peace conference which met at Washington in February, and before the inauguration of Mr. Lincoln as president he with others had a special interview with him to consult upon the means of averting civil war. Mr. Rives was a member of the confederate provisional congress at Montgomery, Ala. He published "Life and Times of James Madison" (3 vols., Boston, 1859-'69).

RIVIERE, Briton. See supplement.

RIVINGTON, James, a royalist printer of New York during the revolution, born in London about 1724, died in New York in July, 1802. Early in life he was a bookseller in London, and acquired a fortune, which he lost at Newmarket. In 1760 he settled in Philadelphia, and in 1761 opened a book store in New York. On April 22, 1773, he established the "New York Gazetteer, or the Connecticut, New Jersey, Hudson's River, and Quebec Weekly Advertiser," in which he advocated the cause of the English government with great zeal. In November, 1775, in consequence of his constant assaults upon Capt. Isaac Sears and other republicans, that officer came from Connecticut with 75 horsemen to New York, destroyed Rivington's press, and converted the types into bullets. In October, 1777, the city being occupied by the British, he resumed the publication of his paper under the old title, which was not long after changed to "Rivington's New York Royal Gazette," and on Dec. 13 to the "Royal Gazette." About 1781, when the success of the British was becoming very doubtful, he played the part of a spy, furnishing Washington with important information. His communications were written on very thin paper, and conveyed to the American camp in the covers of books. After the evacuation of New York Rivington was allowed to remain, much to the general surprise. He took down the royal arms from his paper and changed the title to "Rivington's

New York Gazette and Universal Advertiser." His business however having rapidly declined, his paper was soon stopped (1783), and he passed the remainder of his life in poverty.

RIVOLI, a village of Venetia, Italy, in the province and 12 m. N. W. of the city of Verona, on the W. bank of the Adige; pop. about 1,000. It is memorable for the victory gained here by Bonaparte, Jan. 14, 15, 1797, over the Austrian general Alvinczy, who was marching to the relief of Mantua. This action, in which Joubert and Masséna bore an important part, decided the campaign. The Austrians lost 20,000 prisoners, Mantua surrendered, and the French were enabled to dictate terms at Campo Formio. For his services in this battle Masséna was in 1807 made duke of Rivoli.

RIYAD, or **Riad**, a city of Arabia, capital of the sultanate of Nedjed, in the province of Aared, lat. 24° 38' 34" N., lon. 46° 41' 48" E.; pop. estimated by Palgrave in 1862 at 40,000. It is a nearly square walled town, lying in an open valley, and surrounded by green fields, palm groves, and well watered gardens. It is divided into four quarters, but there is no separation otherwise than by broad streets. The N. E. quarter contains the palaces of the royal family and the houses of state officers and of the richer class; the N. W., an irregular mass of houses, is inhabited chiefly by those who are not strict Wahabees; the S. W., which is spacious and clean, is the chosen abode of the Wahabee orthodoxy; and the S. E., called Khazik (crowded), the worst built part of the town, is the home of the lower classes. The central point where these divisions meet is the market place, with the royal palace on one side and the great mosque on the other, the two being connected by a covered way. The remainder of the square is surrounded by the shops of tradesmen and artisans. Besides the great mosque, a large flat-roofed building capable of holding 2,000 persons, there are 30 or more smaller mosques in the several quarters. The palace is a mass of buildings, generally three stories in height, occupying a parallelogram surrounded by high walls, defended by bastions and towers, and having a dry moat around two thirds of its circuit. The walls of the city, which vary from 20 to 30 ft. in height, are massive and strong, and are defended by a deep trench and embankment. Riyad is the great centre of Wahabism, and all its residents are obliged to conform to the strict rules of the faith. Every morning and evening the names of those whom vicinity obliges to attend prayers are read over in the several mosques, so as to insure presence and detect absentees. The pilgrim route from Persia to Mecca and Medina passes through Riyad. It has been the capital of Nedjed since 1818, when Derayeh, the ancient capital, was destroyed by Ibrahim Pasha.

RIZZIO, **Ritzio**, **Riccio**, or **Ricci**, **David**, a favorite of Mary, queen of Scots, born in Piedmont about 1533, assassinated in Edinburgh, March

9, 1566. He was the son of a poor musician of Turin, went to the court of the duke of Savoy, and thence to Scotland in the suite of an ambassador, who selected him because he was a good linguist. He was made by Mary one of her pages, and after the removal of Raulet he became, in December, 1564, her secretary for the French language. All her foreign correspondence passed through his hands, and upon her marriage with Darnley he was appointed keeper of the privy purse. Darnley attributed Mary's unwillingness to give him the power as well as name of king to the influence of Rizzio, with whom she was also suspected of an illicit intimacy. The favorite's rapid promotion, his arrogance, avarice, and low birth, had aroused the envy and anger of the nobles. By the Protestants he was viewed with disfavor on account of his religion. An agreement, partly written and partly verbal, was entered into by Darnley, Morton, Maitland, Ruthven, Lindsay, and others, for putting Rizzio to death. Just before the execution of the design, Darnley was required to sign another bond in which he gave his assent to whatever they should do. In the evening, while the queen was at supper in company with the countess of Argyll, a few courtiers, her French physician, and Rizzio, the apartment was filled by the armed conspirators. Darnley held the queen, who was in an advanced state of pregnancy; Rizzio cowered behind her and held on to her dress. One or two of the assassins stabbed him in the body, and then dragging him into the antechamber despatched him with more than 50 wounds.

ROACH, a fish of the carp family (*cyprinidæ*) and genus *leuciscus* (Klein). The generic characters have been given under **DACE**. The common roach of Europe (*L. rutilus*, Klein) attains a length of 10 to 15 in.; the upper part of the head and back is dusky green with blue reflections, lighter on the sides, and silvery white below and on the cheeks; the pectorals orange red, ventrals and anal bright red, and the dorsal and caudal pale brown tinged with red. The muzzle is rather sharp, and the

European Roach (*Leuciscus rutilus*).

mouth small with soft lips; there are hooked teeth in the pharynx, and the abdomen behind the ventrals is somewhat keeled; there is a single dorsal in the middle of the back, over the ventrals, which, with the anal, has no bony ray; the nape and back rise suddenly; the

scales are large, with concentric and radiating lines, 43 on the lateral line, which falls by a curve from the upper part of the gill cover below the middle of the body, and thence is nearly straight to the tail. It is found in large shoals in the still rivers and lakes of temperate Europe, and feeds on worms and aquatic plants; it is caught abundantly in the Thames, going high up the river in May or June to spawn, but is best for food and finest in color in October; yet it is not much esteemed. The beautiful dace of New England (*L. [leucosomus] pulchellus*, Girard) resembles the European fish, and hence is often called roach; this name is also applied to the bream (*pomotis vulgaris*, Cuv.).

ROAD, a solid pathway for the transportation of passengers and commodities. Roads are of various kinds, the degree of perfection to which they have been carried generally corresponding to the degree of civilization of the country where they are situated. The ancient Egyptians must have had hard paved roads on which to transport the immense blocks of stone used in building the pyramids and other structures. The Hebrews had roads at a very early period; the song of Deborah speaks of abandoned highways (Judges v. 6). The Greeks paid much attention to roads, but the greatest improvements, such as permanent pavements, are said to have been made by the more commercial Carthaginians. The Via Appia, called by Statius the queen of roads (see **APPIAN WAY**), the Via Aurelia (the Tyrrhenian coast road), and the Via Flaminia (see **FLAMINIAN WAY**) were the first great Roman roads, and the Roman empire soon became intersected with numerous paved roads constructed with great care at enormous expense. In many parts they have lasted till the present day. During the last Punic war a paved road was constructed from Spain through Gaul to the Alps. Similar roads were afterward made in every part of Spain and Gaul, through Illyricum, Macedonia, and Thrace, to Constantinople, and along the Danube to its mouths on the Black sea; and the islands of Sardinia, Corsica, Sicily, and Great Britain were crossed by them. Under Antoninus Pius (A. D. 138-'61) all the Roman military roads were surveyed, including six great roads in Egypt. In India good roads were made at an early period, connecting Agra with Lahore, and Lahore with Cashmere; but after the death of Aurungzebe they fell into decay, and the only good roads in India, it is said, have since been constructed by the British, who have carried a good and metalled road, called the Grand Trunk, from Calcutta to Peshawar on the borders of Afghanistan. The "metalling" (pavement of stone or concrete) of these roads is mostly composed of a calcareous nodule called *kunkur* found there, which when moistened and pounded into a crust nine inches or a foot deep forms an excellent pavement. The *kunkur* is sometimes ferruginous, which im-

proves its quality. In ancient Peru the Incas built great roads, the remains of which still attest their magnificence. The most remarkable were the two which extended from Quito (or in fact nearly 100 m. N. of Quito) to Cuzco, and on toward Chili, one passing over the grand plateau, the other bordering on the ocean. Humboldt, in his "Aspects of Nature," says of the mountain road: "But what above all things relieves the severe aspect of the deserts of the Cordilleras are the remains, as marvellous as unexpected, of a gigantic road, the work of the Incas. . . . In the pass of the Andes between Mausi and Loja we found on the plain of Puttal much difficulty in making a way for the mules over a marshy piece of earth, while for more than a German mile our sight continually rested on the superb remains of a paved road of the Incas, 20 ft. wide, which we marked resting on its deep foundations, and paved with well cut, dark porphyritic stone. This road was wonderful, and does not fall behind the most imposing Roman ways which I have seen in France, Spain, and Italy. By barometrical observation I found that this colossal work was at an elevation of 12,440 ft." Prescott says: "Galleries were cut for leagues through living rock; rivers were crossed by means of bridges that swung suspended in the air; precipices were scaled by stairways hewn out of the native bed; ravines of hideous depth were filled up with solid masonry; in short, all the difficulties that beset a wild and mountainous region, and which might appal the most courageous engineer of modern times, were encountered and successfully overcome. The length of the road, of which scattered fragments only remain, is variously estimated at from 1,500 to 2,000 m. Its breadth scarcely exceeded 20 ft. It was built of heavy flags of freestone, and in some parts at least covered with a bituminous cement, which time has made harder than the stone itself. In some places, where the ravines had been filled up with masonry, the mountain torrents, wearing on it for ages, have gradually eaten a way through the base, and left the superincumbent mass—such is the cohesion of the materials—still spanning the valley like an arch."—The Britons failed to keep up the roads made by the Romans, or to construct new ones, and for centuries they used bridle paths, or at most narrow passages for small carts; and not till the 16th year of the reign of Charles II. was there any attempt by the government to improve the roads. The first turnpike road was then established by law; but it was not till about a century ago that a system of good roads was established. Up to that time goods were conveyed in Scotland on pack horses. In 1770 the journey from Liverpool to Manchester, according to the account of Arthur Young, was not a little perilous from the bad condition of the road. But within the next 60 years, when the manufacturing resources of the country, through the introduction of the steam engine

and the extensive use of coal, were developed, the progress in road making was rapid. In the United States the importance of roads for military purposes, leading into the interior territories and to the frontier, was early appreciated, and some important routes were opened by the general government; as the national road from Baltimore, through Wheeling and Cincinnati, to St. Louis, and that from Bangor to Houlton in Maine. The making of turnpike roads by chartered companies, before the general introduction of railroads, often yielded much profit to capitalists. Most of the paved road was constructed upon the Macadam principle. Several public turnpikes have been constructed in parts of New York and in the western states with planks; but they have not proved successful, as the exposure to air and moisture causes them to decay rapidly.—In laying out a new road, the general system resembles that for the construction of railways, but an equal expense in securing level grades is not usually justifiable. It is found that upon a slope of 1 in 44, or about 120 ft. to the mile, a horse can draw only three fourths as much as he can upon a level; on a slope of 1 in 24, or 220 ft. to the mile, only half as much; and on a slope of 1 in 10, or 528 ft. to the mile, only one fourth as much; but these proportions vary with the condition of the road, because when the road is soft the grade is virtually increased. The harder and firmer and smoother the surface of a road is, the less resistance it will offer to a passing wheel; and for this reason elastic road beds are inferior for the transportation of heavy loads. It is usually estimated that the greatest inclination down which horses may trot with safety is, for roads paved with blocks, 1 in 60; for macadamized roads, 1 in 35 or 40; and for gravel or dirt roads, 1 in 15. In regard to the surface of a transverse section of a road, there has been considerable debate, some maintaining that it should be nearly straight, and that the drainage should be secured when practicable by longitudinal grading, the reason being that ease of draught on a convex road requires the wagon to be in the middle of the track. The weight of authority seems to be in favor of raising the track in the middle, but not to such a degree as to cause much inclination of the wagon. On roads where there is much traffic, so that wagons are continually meeting and passing, inclination may be avoided by having two tracks, each raised in the middle. To allow the water to run longitudinally upon a road bed for any considerable distance will certainly cause any macadamized or stone pavement to get out of order, from washing or undermining, unless it is laid in hydraulic cement, or asphalt of sufficient firmness to resist the action of a rapid current of water. In regard to the formation of the road bed there are two systems, that of Telford and that of Macadam. The system of Telford is principally a revival of that employed by the

old Romans, and also adopted by Trésaguet in France in 1760, but discarded in 1816 by Macadam, who substituted small angular broken stones, laying them directly upon the earth. (See PAVEMENT.) Telford made a return to the system of laying heavy stones at the bottom of the bed and covering them with a coating of broken stones. Several excellent roads were constructed by him in Great Britain, the permanence of which is evidence of his engineering wisdom, such as that between Holyhead and Shrewsbury, and the Glasgow and Carlisle road. Macadam preferred a yielding to a rigid foundation, and even laid broken stone upon boggy ground. The angular shape of the stones caused them to bind together somewhat, but the superiority of roads having large stones or concrete (which is preferable since the manufacture of hydraulic cements has become so general) for a foundation is now generally conceded. The kind of stone most suitable for a road bed is a matter of importance; for macadamized roads, granite or basaltic rock, covered with sandstone or argillaceous shale, is to be preferred. Slate rock in various degrees of hardness may often be employed with advantage as a surface covering as well as a filling in many kinds of pavement where hydraulic cement is not relied on to produce firmness. Of the drainage of a road not much need be said, as it is evident that it should be comparatively dry, and not subject to inundation. A ditch at one or both sides, when the land does not slope away, is almost always necessary, and culverts to lead the water from one side to the other. In carrying a road over a hilly country it is usual to wind around the sides of hills and mountains, and an inclined plane of considerable length often becomes necessary. A ditch upon one side, with frequent culverts, should be constructed; but it is sometimes the practice on turnpikes built by companies, and where the income of the road would not justify the outlay for construction and repair of culverts, to make diagonal elevations across the track at frequent intervals to direct the water off the road. If they are placed too far apart, the water is suffered to gather too much headway and thus wear away the road bed. It is this accelerated movement of water in the ditches of a road running down hill that makes it so difficult to construct culverts which shall receive the current and conduct it away without damage to the banks along the roads.—Public roads are laid out, constructed, regulated, and kept in repair by public authority. Private property is taken for the construction of roads upon allowance of just compensation to the owner. The system of making assessments for repairs varies in the different states. Generally all property owners in the town or county where the road lies are assessed. In many of the states all male inhabitants 21 years old or over are required to labor on the roads a specified number of days each year, but a

substitute may be furnished or commutation be made in money. Females are subject to a property but not to a labor assessment. In large cities special regulations generally prevail.—Among the most important works relating to roads are Macadam's "System of Road-making" (London, 1825); Parnell's "Treatise on Roads" (1838); Telford's reports to parliament on the Holyhead road; Penfold "On Making and Repairing Roads" (1835); Poncelet, *Mécanique industrielle* (Paris, 1841); Morin, *Aide-mémoire de mécanique* (1843); Gayflier, *Manuel des ponts et chaussées* (1844); and Gillespie, "Roads and Railroads: a Manual for Roadmaking" (10th ed., New York, 1871).

ROANE. I. A W. county of West Virginia, intersected by branches of the Kanawha and De Kalb rivers; area, about 450 sq. m.; pop. in 1870, 7,232, of whom 23 were colored. The surface is generally hilly, and in the N. part mountainous, and the soil fertile. Iron ore and coal are found. The chief productions in 1870 were 24,087 bushels of wheat, 160,912 of Indian corn, 28,489 of oats, 4,732 tons of hay, 9,907 lbs. of tobacco, 26,828 of wool, 116,094 of butter, 6,922 of flax, and 28,836 gallons of sorghum molasses. There were 1,540 horses, 1,858 milch cows, 3,477 other cattle, 12,973 sheep, and 7,112 swine. Capital, Spencer. **II.** An E. county of Tennessee, intersected by the Tennessee river and drained by its branches, the Clinch and Holston; area, about 600 sq. m.; pop. in 1870, 15,622, of whom 2,128 were colored. Along the W. border is a range of the Cumberland mountains. The soil is generally fertile. The East Tennessee, Virginia, and Georgia railroad passes through it. The chief productions in 1870 were 74,814 bushels of wheat, 504,590 of Indian corn, 112,029 of oats, 1,671 tons of hay, 14,027 lbs. of wool, 163,394 of butter, and 13,080 gallons of sorghum molasses. There were 3,390 horses, 3,064 milch cows, 5,623 other cattle, 10,552 sheep, and 17,661 swine; 1 manufactory of cotton goods, 1 of pig iron, 9 of tanned and 8 of curried leather, 4 wool-carding and cloth-dressing establishments, and 5 saw mills. Capital, Kingston.

ROANNE, a town of France, in the department of Loire, on the left bank of the Loire, 40 m. N. W. of Lyons; pop. in 1872, 20,037. It is well built, and has fine promenades, a wide quay, and a stone bridge 620 ft. long, with seven arches. The town has a college with a library of about 10,000 volumes, a church of the 15th century, a city hall, dyeing establishments, tanneries, flax and cotton mills, and hat shops. It is celebrated for its mineral waters. A canal connects it with Digoin. It is the great entrepot for the product of the Loire coal fields. It contains numerous Gallo-Roman antiquities.

ROANOKE, a S. county of Virginia, intersected by Staunton river, bordered S. E. by the Blue Ridge and N. W. by a ridge of the Alleghanies; area, about 200 sq. m.; pop. in 1870, 9,350, of whom 3,132 were colored. It

occupies part of the great Virginia valley, and has a very fertile soil. It is traversed by the Virginia and Tennessee division of the Atlantic, Mississippi, and Ohio railroad. The chief productions in 1870 were 203,226 bushels of wheat, 86,943 of Indian corn, 89,558 of oats, 3,481 tons of hay, 280,550 lbs. of tobacco, 4,365 of wool, 120,980 of butter, and 4,600 gallons of sorghum molasses. There were 1,846 horses, 5,075 cattle, 2,208 sheep, and 7,344 swine. Capital, Salem.

ROANOKE RIVER. See NORTH CAROLINA, vol. xii., p. 489.

ROBBERY, in law, a felonious taking of money or goods, of any value, from the person of another or in his presence, against his will, by violence or putting him in fear. The characteristic feature of this offence, and that which makes the distinctive difference between it and simple larceny from the person (or between a robber and a cutpurse or common thief), is the violence and fear attending its perpetration; and therefore it makes no material difference whether the thing taken be of great or small value, though it must be of some real value, for otherwise it is no larceny and consequently no robbery; and there must also be an actual taking of something, for the violence and putting in fear alone would amount only to an assault. It is not necessary that the money or property should be taken directly from the person or manual possession of the owner in order to constitute this offence. If it be taken in the actual presence of the owner, and violence be offered to his person, or he be put in fear for the purpose of accomplishing such a taking, this amounts to the same thing; as if, for instance, a robber should assault a man and command him to deliver up his purse, but instead of doing so the owner should throw it away from him, and the robber should then pick it up and carry it off in his presence, this would be as much a robbery as if he had taken it from the owner's person. The robber must have obtained actual possession of the property, but it is not material that such possession should continue; and though for any reason the robber should return the money stolen the next moment after receiving it, either absolutely or conditionally, yet this will not alter the crime, or render its consummation less complete. A sudden snatching of a thing from the hand or person of another is not such a taking by force and through fear as will constitute robbery, unless it occasions either an injury to the party from whom it is snatched, or a struggle for the possession of the property taken; for here there is no putting in fear; and though a certain degree of force may be used, the theft is accomplished rather without than against the consent of the owner, and more by the dexterity of the thief and the sudden surprise of the party than by open force and terror. But where an ear ring was so suddenly pulled from a lady's ear that she had neither time nor opportunity for resistance, it being done with such violence

that her ear was entirely torn through, the perpetrator was held guilty of robbery. The violence and putting in fear, moreover, must precede the taking. If a man quietly steal anything from the person, though he afterward retain possession of it by violence or by intimidating the owner, this is not robbery; for the fear is subsequent to the larceny, and no violence subsequently used, even with respect to the same thing, will operate so as to convert that into robbery which was before only larceny. But if a man be knocked down without any previous warning, and then stripped of his property while senseless, though he could not properly be said to have been previously put in fear, yet it would be a robbery. If the violence be fraudulently used under color of some legal proceeding; or if money be forcibly extorted under pretence of a purchase or sale; or if a man beg in a menacing manner, as with a drawn sword in his hand, and receive alms from the party through the apprehensions regarding his personal safety which the appearance and actions of the beggar naturally excite in his mind; in all these cases it will still be robbery. Thus, where the prisoner forcibly took a bushel and a half of wheat worth 8s. from a woman, and compelled her to accept 13d. for it, threatening to kill her if she refused, this was held to be robbery by all the judges in England. It is not necessary that the delivery of the money or goods should be contemporary with the violence or the immediate effect of it; as, if a robber, finding but a small sum of money about a man's person, compel him to swear under a threat of death in case of non-compliance to bring him a larger sum, which the man does, this is robbery, because the terror caused by such a menace is upon him at the time of his making the payment, and was the cause of his doing so.—The payment of money or delivery of goods by the owner, under the fear of having his property destroyed, is robbery in the receiver. And it is an important rule that the violence is sufficient to make the crime robbery, although it consist entirely of a threat to disgrace a person. The fear arising from a menace of accusing one of a dreadful crime which would endanger his personal safety, or lead to the loss of his character or situation, is equivalent to the fear of personal and immediate violence; and to extort money by such means is robbery. But the fear thus excited must not only be such as will suffice to influence or even to constrain the ordinary action of the will; it must entirely and immediately control and overpower it, and render the person incapable through terror or confusion of resisting the demand. For this reason, in a case where the prosecutor, who was threatened with having such a charge made against him unless he complied with the prisoner's demand, did not part with his money immediately upon the threat being made to him, but on the contrary did so after the person making the threat had left him, and af-

forded him sufficient time in which to consider the matter, and apply for assistance if he desired so to do, and after he had consulted with a friend who was actually present when he paid the money, here it is considered that the prosecutor was not impressed with such terror as to render him incapable of resisting the demand; that there was not the continuing fear which could operate *in constantem virum* from the time when the money was demanded until it was paid; and consequently there was neither the actual nor constructive violence which was necessary to constitute the crime of robbery. Further, it is not necessary that the fear should be of violence to the person robbed. If the threat is made against a man's wife or child, or other person to whom he is bound by ties of blood and affection, and he gives money to the robber for the sake of saving such person from immediate danger or violence, this would be as much a robbery as if the violence were offered to himself. Neither is it necessary that the robbery should be the sole and original motive of the person making use of the violence, if the violence so used led to this result; as, where a man feloniously assaulted a woman, who, without any demand on his part to that effect, offered him money, which he took, yet continued to treat her with violence, for the accomplishment of his original purpose, until interrupted by the approach of others, this was held to be a robbery; for the woman, terrified by the prisoner's behavior, offered the money to save herself from further violence, which otherwise she would not have given voluntarily.—It was a principle of the common law that no restitution of stolen goods could be awarded upon an indictment, inasmuch as it was at the suit of the king only, and the owner could only obtain restitution by an appeal of robbery, which was the suit of the party; but this has long fallen into disuse, and subsequent statutes have remedied the defect. Formerly, when a robbery or other felony had been committed in England, a hue and cry should be raised, which was the old common law process of pursuing with horn and with voice all felons. In this hue and cry all persons, both officers and private individuals, were called upon to join; and no hue and cry was deemed sufficient unless made with both horsemen and footmen. In order that such hue and cry should be more effectually made, the hundred was bound to answer for all robberies therein committed unless they captured the felon; and this responsibility is the foundation of the ancient action against the hundred for any loss by robbery. If the robber was taken, the hundred stood excused; but otherwise the party robbed was entitled to prosecute it by a special action on the case for damages equivalent to his loss. In order further to encourage the apprehending of robbers, certain rewards were offered to such as would bring them to justice, by various acts of parliament, one of which enacted "that such as

apprehend a highwayman and prosecute him to conviction shall receive a reward of £40 from the public, to be paid to them by the sheriff, together with the horse, furniture, arms, money, and other goods taken upon the person of such robber, saving only the rights of any persons from whom the same may have been stolen."—Robbery has always been considered an aggravated crime, especially when committed with dangerous or deadly weapons, and was formerly punished with great rigor and severity. Until comparatively recent times it was indeed punished with death, here as well as in England, even though the amount stolen would, if unaccompanied by violence, have constituted only petit larceny. This was the rule of the common law; but the progress of civilization, restricting capital punishment to a few crimes, has modified the penalty for robbery, as a general thing, to imprisonment for life, or for a term of years, according to the particular circumstances and degree of the crime.

ROBERT GUISCARD. See GUISCARD.

ROBERT I., king of Scotland. See BRUCE.

ROBERT, Louis Léopold, a French painter, born in La Chaux-de-Fonds, Switzerland, May 13, 1794, died in Venice, March 20, 1835. At first he applied himself to engraving, and subsequently to painting under the instruction of David and Gérard. In 1818 he went to Rome, where he pursued his art with singular enthusiasm. He was a laborious painter, rejecting picture after picture which seemed to him unequal to the subject, and occupying in some instances years upon a single work. His productions are few, but in the delineation of Italian life are unrivalled in modern art. His masterpieces are the "Reapers," the "Neapolitan Improvisatore," the "Madonna dell' Arco," and the "Fishermen of the Adriatic." He conceived a romantic but hopeless passion for a beautiful woman of rank, under the influence of which he committed suicide.—See *Léopold Robert, sa vie, ses œuvres et sa correspondance*, by Feuillet de Conches (Paris, 1862).

ROBERT, Louis Valentin Éllas, a French sculptor, born in Étampes about 1818. He studied under David d'Angers, and has produced "France crowning Art and Industry," a colossal group on the palace in the Champs Élysées (1855), four caryatides for the opera at Philadelphia (1857), several for the new Paris opera opened in 1875, a bust of Houdon in the Louvre, a statue representing the drama, busts for the Châtelet theatre, and a bronze statue of Justice which decorates the fountain of St. Michel in Paris.

ROBERT-FLEURY, Joseph Nicolas, a French painter, whose real name is Fleury, born in Cologne, Aug. 8, 1797. He studied under Vernet and Gros, and exhibited his first piece in 1824. Among his works are: "Tasso in the Convent of St. Onofrio," "An Incident of the St. Bartholomew Massacre," "The Last Moments of Montaigne," "The Entrance of Clovis into Tours," and "Jane Shore." One of his finest productions, "Charles V. at the Mon-

astery of San Yuste," was again exhibited in 1867. He has been professor, and for five years director, of the school of fine arts in Paris, and in 1865-'6 of the French academy in Rome. His son Tony is a historical painter.

ROBERTS, David, a British artist, born at Stockbridge, near Edinburgh, Oct. 24, 1796, died in London, Nov. 25, 1864. In early life he was a house painter, and upon removing to London in 1821 he devoted himself for several years to scene painting. In 1832-'3 he visited Spain, and upon his return published a volume of lithographic copies of "Picturesque Sketches in Spain" (1837). In 1838-'9, during a tour through Syria and Egypt and other eastern countries, he made a number of drawings, published as "The Holy Land, Syria, Idumæa, Arabia, Egypt, and Nubia" (4 vols. fol., 1842-'8). In 1841 he was elected a royal academician, and subsequently produced a number of views of celebrated places, with architectural and other accessories, including "Ruins of the Great Temple of Karnak," "Jerusalem from the Mount of Olives," "Rome," "Interior of the Cathedral at Burgos," "The Chancel of the Collegiate Church of St. Paul at Antwerp," &c. His works also include such subjects as the "Destruction of Jerusalem," and the "Inauguration of the Exhibition of all Nations," painted for the queen. At his death he left in his studio 73 oil paintings and sketches and 800 water-color pieces, which were exhibited in 1865 and subsequently sold for £16,000.—See "Life of David Roberts, R. A.," by James Ballantine, illustrated with sketches by the artist (4to, Edinburgh, 1866).

ROBERTSON. I. A central county of Texas, bordered E. by the Navasoto river and W. by the Brazos, and drained by their branches; area, 840 sq. m.; pop. in 1870, 9,990, of whom 4,530 were colored. It has a rolling surface, covered with forest and prairie, and a generally fertile soil, with some very rich bottom lands. It is traversed by the Houston and Texas Central railroad. The chief productions in 1870 were 140,083 bushels of Indian corn, 1,385 lbs. of wool, and 4,833 bales of cotton. There were 897 horses, 1,854 milch cows, 8,648 other cattle, 5,156 sheep, and 7,817 swine. Capital, Calvert. **II.** A N. county of Tennessee, bordering on Kentucky, and drained by tributaries of Cumberland river; area, about 400 sq. m.; pop. in 1870, 16,166, of whom 4,813 were colored. It has an uneven surface and a generally fertile soil. The St. Louis and Southeastern railroad passes through it. The chief productions in 1870 were 161,114 bushels of wheat, 559,020 of Indian corn, 149,019 of oats, 19,295 of Irish and 27,455 of sweet potatoes, 2,103,322 lbs. of tobacco, 19,387 of wool, and 155,643 of butter. There were 3,908 horses, 2,461 mules and asses, 3,000 milch cows, 3,290 other cattle, 11,146 sheep, and 29,817 swine; 8 flour mills, 14 saw mills, and 12 distilleries. Capital, Springfield. **III.** A N. E. county of Kentucky, bounded N. by Shannon creek and S. W.

by Licking river, and drained by several tributaries of the Licking; area, about 175 sq. m.; pop. in 1870, 5,399, of whom 257 were colored. The surface is rolling and in some parts hilly; the soil is fertile. The chief productions in 1870 were 9,913 bushels of wheat, 11,176 of rye, 242,426 of Indian corn, 16,667 of oats, 1,648,201 lbs. of tobacco, 84,675 of butter, and 769 tons of hay. There were 1,931 horses, 961 milch cows, 1,213 other cattle, 2,289 sheep, and 5,412 swine. Capital, Mount Olivet.

ROBERTSON, Frederick William, an English clergyman, born in London, Feb. 3, 1816, died in Brighton, Aug. 15, 1853. His early inclinations were toward military life, but he entered Brasenose college, Oxford, where he graduated in 1840, and the same year took orders. He was curate successively at Winchester, Cheltenham, and Oxford; and in 1847 he became minister of Trinity chapel, Brighton, where his eloquence and originality always attracted a crowded and intellectual audience. He organized a working men's institute, before which he delivered several lectures. The violent denunciations of some of his religious opinions, acting on a naturally feeble constitution, hastened his death. He was the author of "Lectures on the Influence of Poetry on the Working Classes" (London, 1852; republished with additions under the title "Lectures and Addresses on Literary and Social Topics," 1858; new ed., 1861); "Sermons preached at Trinity Chapel" (four series, 1855-'63; new ed., with a memoir, 2 vols., Boston, 1870); and "Expository Lectures on St. Paul's Epistles to the Corinthians" (London, 1859). His "Life and Letters" have been edited by Stopford A. Brooke (2 vols., 1865).

ROBERTSON, James Cragie, a British clergyman, born in Aberdeen, Scotland, in 1813. He graduated at Trinity college, Cambridge, in 1834, took orders in the English church, in 1846 became vicar of Beaksbourne near Canterbury, and in 1859 was appointed canon of Canterbury. He was chosen professor of ecclesiastical history in King's college, London, in 1864, which chair, in conjunction with his canonry, he still holds (1875). His chief work, the first volume of which was published in 1853, is "History of the Christian Church, from the Apostolic Age to the Reformation" (revised ed., 8 vols. 8vo, 1874-'5). He has also published "How shall we conform to the Liturgy of the Church of England?" (1843; 3d ed., 1869); "The Bearings of the Gorham Case" (1850); "Becket, Archbishop of Canterbury, a Biography" (1859); and "Church History during the First Six Centuries" (12mo, 1869). He has edited for the ecclesiastical history society Heylin's "History of the Reformation of the Church of England" (1849), and for the Camden society Bargrave's "Alexander VII. and his Cardinals" (1866).

ROBERTSON, Thomas William, an English dramatist, born Jan. 9, 1829, died in London in February, 1871. He belonged to a theatrical

family, and began life as an actor in a strolling company, of which his father was the manager. His first original drama, "A Night's Adventure," was brought out at the Olympic in 1851. He settled in London in 1860, supporting himself by light literature. His "David Garrick," adapted from the French, attracted general notice in 1864, chiefly owing to the acting of Sothorn. His "Society," produced at the opening of the Prince of Wales's theatre in 1865, made him famous, and was followed by "Ours" (1866), "Caste" (1867), "Play" (1868), "School" (1869), and "M. P." (1870). His last play was "War," produced at the St. James's Theatre.

ROBERTSON, William, a Scottish historian, born at Borthwick, Edinburghshire, Sept. 19, 1721, died at Grange house, near Edinburgh, June 11, 1793. He graduated at the university of Edinburgh in 1741, was licensed to preach, and in 1743 was presented to the living of Gladmuir in Haddingtonshire. In 1745 he volunteered to serve in the army against the pretender. In the general assembly of the church of Scotland he was one of the leading advocates of lay patronage, which at that time was the great dividing question. In 1757 he defended Home, who was persecuted by the ultra Calvinist party for writing the tragedy of "Douglas," and also the clergymen who had attended the theatre to witness its representation. In 1759 he was made chaplain of the garrison at Stirling, in 1761 a dean of the chapel royal, in 1762 principal of the university of Edinburgh and minister of the old Greyfriars, and in 1764 historiographer of Scotland with a salary of £200. About this time he entertained the project of writing the history of England; but after the resignation of Lord Bute, who had been his friend, he gave it up. His histories vie with those of his contemporaries Hume and Gibbon in diction and liberal sentiment, and surpass them in impartiality. They are: "History of Scotland during the Reigns of Mary and James VI." (2 vols. 4to, 1759); "History of the Reign of the Emperor Charles V." (3 vols. 4to, 1769); and "History of America" (2 vols. 4to, 1777); besides "An Historical Disquisition concerning the Knowledge which the Ancients had of India" (4to, 1791). His life was written by Dugald Stewart (8vo, 1801), and by Lord Brougham.

ROBERVAL, Gilles Personne or Personier de, a French mathematician, born at Roberval, near Beauvais, Aug. 8, 1602, died in Paris, Oct. 27, 1675. He went to Paris in 1627, became professor of philosophy in the college of Maître Gervais and of mathematics in the royal college, and was one of the members of the academy of sciences at its foundation in 1665. He early discovered a method of investigating problems similar to the "method of indivisibles," but kept it to himself in order to surpass his contemporaries in the solution of problems, and thus lost the honor of originating

it. A method of determining the direction of a tangent at any point of a curve, which Torricelli claimed to have made in 1644, Roberval, in a letter to Torricelli, declared was known to himself in 1636. Torricelli gave the name of Robervallian lines to curves with infinite branches which admit of an expression for the area between them. Roberval discovered rules for finding the volume of solids formed by the revolution of a cycloid about its base and about its axis. His principal works were published after his death in the old *Mémoires de l'Académie*, vol. vi. (1693).

ROBESON, a S. county of North Carolina, bordering on South Carolina, watered by the Lumber and Little Pedee rivers; area, about 900 sq. m.; pop. in 1870, 16,262, of whom 737 were colored. It has a nearly level surface and a generally sandy soil. It is intersected by the Carolina Central railroad. The chief productions in 1870 were 5,838 bushels of rye, 138,545 of Indian corn, 21,261 of peas and beans, 84,784 of sweet potatoes, 69,486 lbs. of rice, 14,081 of wool, 25,199 of honey, and 2,109 bales of cotton. There were 1,152 horses, 741 mules and asses, 2,915 milch cows, 6,469 other cattle, 8,396 sheep, and 18,751 swine; 1 saw mill, and 15 establishments for the production of tar and turpentine. Capital, Lumberton.

ROBESPIERRE, Maximilien Marie Isidore de, a French revolutionist, born in Arras, May 6, 1758, executed in Paris, July 28, 1794. He was supposed to be of remote Irish origin, and his ancestors had acquired patents of nobility in France. His mother died young, and his father deserted his family and ended his life in Germany. His grandfather placed him at the college of Arras, and M. de Conzié, the bishop, sent him in 1770 to the college of Louis le Grand in Paris. Danton, Desmoulins, and Fréron the younger were among his fellow pupils. He repeatedly gained honorable distinction in his studies, and remained at this institution eight years. After completing his law studies he returned to Arras, where his first important cause was a defence of the introduction of Franklin's lightning rods against the charge of impiety (1783). He became a member of the criminal court of Arras, and in the discharge of his duties was called to condemn a prisoner to death. This so affected him that he resigned his office and advocated the abolition of capital punishment. He was thoroughly imbued with the theories of Rousseau, and gradually espoused the cause of the people in opposition to the clergy and nobility. On the convocation of the states general in 1789, he was elected deputy of the third estate. Lamartine describes his figure as slight; limbs feeble and angular; voice shrill and monotonous; forehead small and projecting over the temples; eyes blue and deeply set; nose straight and small, and very wide at the nostrils; mouth large and lips thin; chin small and pointed; complexion yellow and livid. There was a prodigious and continual tension of all the muscles
